

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

A JOURNAL OF ART, CIVIL ENGINEERING & BUILDING.

THE WEEK.

THAT H.M. the KING has been so far restored to health as to be able to spend his Christmas as usual at his favourite Norfolk home is not only a matter of pleasurable satisfaction to his loyal subjects, but must redound to the credit of "Dr. Brighton," whose practice of late years has been very markedly declining. Undoubtedly one potent cause, if not the chief one, of the waning popularity has been the hopelessly antiquated character of much of the house property, not only in Brighton proper, but even in its younger neighbour and rival, Hove. Tall-built houses with basements often almost dark, with appalling flights of stairs, no lifts, frequently no bathroom, and with infinitesimal backyards, are enough in these days to deter the public from any seaside town, however salubrious or convenient of access. *En passant*, the convenience of access to Brighton is capable of considerable improvement. For architects who have clients able and willing to invest money in profitable enterprise there are hundreds of opportunities in the modernisation or reconstruction of property, both residential and commercial, in Brighton and Hove.

THE terrible catastrophe that has this week befallen Sicily and Calabria not only demands and receives our sympathy with the loss of human life and the sufferings of those who have escaped with barely more than life, but arouses our fears for the art treasures that, to architects, form the most outstanding characteristic of Sicily and Magna Græcia. Messina, which, so far as news has at present reached us, is the worst sufferer by the present calamity, has so frequently been visited by earthquakes, and notably in 1783, that its store of antiquities cannot compare with those in other parts of the island. So severe a shock can, however, scarcely be confined to a very limited area, and we wait with feelings of apprehension for news of lesser but still serious injury elsewhere.

A MOVEMENT has been set in motion by the local JOHN EVELYN Club for the acquisition of an area of 220 acres as an addition to the Wimbledon and Putney Commons. The fields are between these commons, and at one end is Richmond Park, and Coombe Wood at the other. A large part of the area, which belongs to the family of the Duke of CAMBRIDGE, is now to be let for building purposes. The price has still to be settled by negotiation. The committee have explained that they will not agree to any terms higher than those which a prudent and substantial bidder, concerned exclusively to make a profit for his own private advantage, would offer. If the land is now comparatively cheap, it is because a very large outlay would be necessary in road-making and drainage to develop it as a building estate; because no railway station lies near, and, as yet, no tramway provides communication; and, lastly, because it is not close to any industrial or trading quarter. If the chance of buying is let slip by, the roads will be made and the tramways pushed as part and parcel of a great building enterprise. A private resident has provisionally accepted responsibility for the purchase of a strip of thirteen acres at 280*l.* an acre. The organising committee wisely point out that local enthusiasm must show itself before an appeal for help can be made to outside sympathy. The movement has received the necessary approval of the Conservators of the Wimbledon and Putney Commons. It is suggested that if the subscriptions are insufficient to purchase the area outright, there remain various expedients to avert any serious disfigurement. These include the erection of residences on certain special sites, such as those fronting the Kingston Road, whereby the cost of purchase should be materially decreased. But the JOHN EVELYN Club see no reason why public and private contributions should not be sufficiently generous to enable the area to become an absolutely free public open space. Hampstead Heath has been extended for the third time at a cost of 43,000*l.*

ROME has already, by the developments that have followed the abolition of the temporal power of the Papacy, lost so much of its interest for the artist and the antiquarian that the latest schemes of the municipal authority, involving the destruction of many of the historical monuments of the city, both Mediæval and Renaissance, have caused alarm not only to all those who value the antiquities of Rome for their own sake, but to those who are shrewd enough to understand that these constitute a very potent attraction to the many foreign visitors, whose gold is the mainspring of a large proportion of Rome's business activity. Amongst the monuments threatened is the church of Santo Spirito, which, on account of the records in its priceless frescoes of the Greek notables driven out by the Turkish conquests, has enlisted the sympathy of the Greek Historical Society of Athens and drawn from that body a petition to the Italian Government for its intervention. Of still more general interest is the passage connecting the Vatican and the castle of St. Angelo, whose existence is also threatened. Even the remains of the old walls of Rome are in jeopardy. The excuse for the proposed vandalism is the housing of the working classes, but one of the most striking peculiarities of Rome to visitors is the proximity of the open country to the city's boundaries. We almost said outskirts, but Rome has no outskirts. It would surely be better for the working classes to live in "garden cities" or suburbs outside the gates than to be cooped up in flat-dwellings within the city. True that the Romans of the Republic and the Empire lived in "insulæ," but Italians of the twentieth century have surely imbibed sufficient modernity to respect the works rather than the practices of antiquity.

WHILST Fletton bricks sell at 11*s.* a thousand there is not much opening for sand-lime bricks in this country, but their manufacture has found so much favour in Germany that the output is now something like a thousand millions annually, and when our next boom arrives in English building, we may expect to see these bricks competing with our usual clay goods.

THE ABUSE OF COMPETITIONS ON THE CONTINENT.

By LAWRENCE HARVEY, of Geneva.

SOME fifteen years ago the Institute of British Architects took measures to prevent the victimising of their profession by competition-mongers. Apart from the suspicious circumstances which were often met with in the organisation of architectural competitions, it was shown that under the best arrangements then prevailing architectural competitions were very detrimental to the interests of the profession. In one case the money spent by the competitors was more than the cost of the building to be erected. A really monstrous abuse! Usually the secret motive of putting to competition the designing of a public building was that several influential members of the committee had each some person to whom they would like to entrust the job. As they could not openly get him appointed they asked for a public competition in the hope that they would be able to influence their friends of the committee to give the prize to their *protégé*. As committees have neither soul to be saved nor back to be kicked, the trick often succeeded. We speak in the past tense, for we hope that England is become since then so moral that those things could not occur now.

According to the regulations of the Institute, those who set up competitions are obliged to submit to certain conditions which secure as much as possible a fair treatment of the competitors. In our opinion the most important of those conditions is that the judging of the competition should be entrusted to one paid arbitrator. All shuffling of responsibilities is thereby rendered impossible. Left alone to face public opinion, a man of even no heroic virtue feels intensely his responsibility and will take every pains to judge rightly according to his lights. He will probably be most willing to give the reasons of his award, even if they be not asked. This does not mean that the arbitrator's award will please everybody or even most of the interested parties. We remember the late lamented CHARLES BARRY, when President of the Institute, having to act as arbitrator in the competition of designs for the Edinburgh Town Hall. In order to do his work conscientiously he had made a list of the points which decided the relative value of the designs. For each design he gave marks from one to ten for each point: so much for general circulation, so much for convenience, so much for impressiveness of outside or inside, &c., &c. According to the relative importance of the points he multiplied his figures by a co-efficient, one might be five, the other two, the other only one. Then for each design he added all the marks together, and gave his award to the design which obtained the highest total. The result of all this painstaking labour was that everyone was displeased with the award. At all events, however, no one could entertain the slightest suspicion of dishonesty or even slovenliness in the arbitrator's decision.

This is far from being the case at the present time on the Continent, where the system of juries or committees still prevails for awarding the prizes in architectural competitions. One of my Paris confrères, now a well-known architect, competed many years ago for the designing of a group of schools near Paris. Some time afterwards he met one of his school chums who had been appointed a member of the jury, and he told him he had competed and failed. His friend, the eminent member of the jury, said, "It serves you right; you should have shown me your design before you submitted it for competition, and I would have seen that proper notice was taken of it." My Paris confrère added, "In France it is no use competing unless you have friends on the committee or the jury." Even for the scholastic competition of the Grand Prix de Rome the competitors manage to make their designs known to their friends on the jury. A candidate is not considered a serious competitor if he does not. Thanks to the Royal Institute of British Architects we have done with this shameful state of things in England.

With juries to judge architectural competitions irregularities occur which, though not so morally base as what we are told exists in France, are equally unfair and disastrous to the majority of competitors. Some twenty years ago the Swiss Confederation opened a competition for the designing of a central post-office in Geneva. More than a hundred designs were sent in. Yet the jury, without a moment's hesitation, selected unanimously two designs which they considered far above all others. When the names of the authors were disclosed it was discovered that both designs, although entirely different from one another in every particular, were the work of the same firm of architects. This appears very strange, but when explained is simple enough. Up to that time the Swiss Government had shown itself exceedingly economical in its public buildings. The conditions published for the competition underscored this necessity for economy, for it was said that flats should be comprised in the building above the part reserved to the post-office, which flats would be let to private individuals. Now, the winning competitors were intimate friends of the chief of the Federal Board of Works, and in a private interview they heard from him that the Federal Government was enormously rich, and wished to give Geneva the most magnificent post-office possible irrespective of cost, as an acknowledgment for the generous way in which Geneva had received the Federal shouting match.

Now, acting on this information, the firm prepared the two monumental designs to which the jury awarded the palm. In the design selected the flats are represented by one room in the roof. The result is that Geneva possesses in its post-office a monument more impressive than anything of its size to be seen in either London or Paris; but the hundred other competitors have been tricked for all that, and we do not think that any arbitrator would have taken the responsibility of such unfair treatment.

Committees who get up competitions have no more feeling for the professionals who compete than children have for worms they tread under foot. It matters not to them what trouble they give or to what expense they put competitors. The recent international competition for the Monument of the Reformation at Geneva is a most painful example of this kind of victimising competing artists. The architects and sculptors of all countries were invited to send designs for placing a monument somewhere in a large park, so that the game of chance was this, "Your design is splendid, but we do not approve the site you select, and therefore your work is null and void." There was nothing to enable a competitor to know which would be the best site. The design selected by the jury is on a site which offers many drawbacks both practical and æsthetic. As a proof we may observe that nearly the whole population of Geneva, with the exception of the committee and a few friends, is hostile to the successful design. If the committee had required of competitors mere sketches needing very little manual labour, as a preliminary to a final competition in which only a limited number of artists, paid for their work, would have been invited to compete, nobody could complain. But this was not the case; plans involving much labour were demanded, even sculptural details had to be forwarded. For any man who has some fellow-feeling for those who work, the sight of the exhibition of designs for the Geneva Reformation Monument was most painful. Seventy-one designs had been sent from all parts of the world, several from England. Most involved enormous labour, and models, the making of which must have cost from four hundred to eight hundred pounds sterling, exhibited admirable workmanship. All this in vain, to give as a result the selection of a wall with a few statues against it, which will cost, perhaps, five thousand pounds sterling to carry out. If there be any backsliders in England who regret the good old times when competitions were not regulated by the Institute, let them consider the facts which are to be seen on the Continent, and be wise.

FAIR WAGES.

THE report has been issued of the Fair Wages Committee appointed in August 1907 to consider how best effect might be given by Government departments to the resolution passed by the House of Commons on February 13, 1891, the object of which was "to secure the payment of such wages as are generally accepted as current in each trade for competent workmen."

It cannot fairly be contended that such an object is a pandering to Socialism or a submission to the tenets of trades unionism. The Government, as the largest individual employer of labour in this country, naturally desires that its work shall be carried out by "competent workmen," and rightly recognises that this cannot be achieved except by the payment of fair wages. In many departments of Government work the very assurance of our national existence depends upon the integrity of the labour of competent workmen. The rivetting of a battleship, the accuracy of the sights of a 12-inch gun are matters of which no amount of supervision can insure the perfection without the exercise of the skill and thoroughness of competent workmen. The results of the lack of such skill and thoroughness have been seen quite recently in the construction of foreign battleships.

Even if it were possible to obtain satisfactory work without the payment of fair wages, it is obvious that in Government work such a consummation would imply a clever manipulation of unfair taxation. When a competent workman in Government employ is paid a fair wage for his skill and thoroughness the cost is divided amongst the community, with whatever degree of fair division is represented by the Budget proposals of the Chancellor of the Exchequer. If, on the other hand, he were inadequately paid for good work, he would be taxed to that extent in favour of the remainder of his fellow countrymen. In Germany the cash expended by the Government on the maintenance of each individual soldier is considerably less than in our own country. Why? Because the soldier personally bears the super-tax of the cost of his keep. Such a method of indirect taxation is not yet—and, we hope, never will be—part of our fiscal system. Every Englishman desires that his Government shall be served by competent workmen, and that these shall receive fair wages for their services.

The line taken by the Government must necessarily influence the policy of other governing bodies, municipal and public authorities; and fair wages for competent workmen must become the general rule wherever public money is being expended for the public benefit.

Already it has become quite a common custom for our municipal authorities to insert, as a condition in their contracts, the payment of the trade union rate of wages. The Fair Wages Committee, however, in their report discriminate rightly between "trade union conditions" and fair wages. Frequently, no doubt, the trade union rate of wages is "generally accepted as current for competent workmen," but not necessarily always, and therefore the Committee recommend proposals to insure, without dependence on trade unions, the payment of fair wages.

We cannot but think that it would be advisable for architects in their own interest, as well as in that of their clients, to adopt one in particular of the proposals of the Committee—"that the contractor should be required, when tendering, to furnish a schedule of the rates of wages and hours of labour which he proposes to pay and observe in the execution of the contract."

It has now become so universal that contracts are given to the lowest tenderer, that it is important for architects to be able to put all contractors submitting tenders on the same basis. The quality of materials can be adequately defined by a well-drawn specification; the form of the work is explicitly determined by the drawings; but the precise degree of excellence of the workmanship is practically impossible of definition in a specification.

How often it happens that an architect, saddled with the supervision of the work of the lowest tenderer, finds his labour, his anxiety, and his responsibility increased to a heart-breaking extent because the contractor is bent upon making his profit on the lowest tender by the employment of an undue number of so-called "apprentices," or, in plain English, incompetent workmen ready to accept unfair wages. As it is usually the client most keen on getting his work done at the lowest possible figure who is most exigent of the ability of his architect to obtain for him a higher quality of workmanship than that for which he is willing to pay, the result is dissatisfaction, recrimination, and possibly a law suit, in which the architect may be cast in damages under the somewhat severe view which the Courts now seem inclined to take of the responsibility of the architect and the meaning of "negligence."

It would surely be a strong defence to any charge of negligence if it could be shown that a client willingly accepted the tender of a contractor who proposed to pay 6*d.* an hour to his workmen, when his competitors were prepared to give 9*d.* On the other hand, it is but just to the client who is willing to pay a fair price for a good article that he should be assured that he will receive the work of competent workmen fairly paid.

Nor is it only in respect of "labour" that the principle of fair wages for competent workmen holds good. It applies with equal force to the professional man or artist as to the artisan or craftsman. It is an unfortunate result of the wording of the schedule of charges of the Royal Institute that the public has come to understand by the statement that the "usual remuneration" of an architect is a commission of 5 per cent. that this is the universal remuneration—except when he is content to take less.

For some classes of buildings, as workhouses, large asylums, or hospitals, 5 per cent. is no doubt too high a remuneration, and even our leading specialists would be receiving fair wages at a lower figure. But, taking the general bulk of architects' work, is it conceivable that the services of a newly-elected Associate are of equal value to those of the architect who is a member of the Royal Academy, or President or Vice-President of the Royal Institute? If 5 per cent. is a fair wage for the fledgling, surely the services of the tried and proved artist, of the experienced practitioner, are of greater value, and should receive higher remuneration to constitute fair wages. In no other art or profession does such a state of things exist as in architecture. In painting, sculpture, law, medicine, in every sphere, the men at the top of the tree receive higher fees than those at the foot. Even in architecture we do not find that the trade-union idea of an universal wage for every man obtains generally out of England.

If 5 per cent. is fair wages for the Royal Academician or an Institute President, it is unreasonable to expect that the public should be willing to pay or that the youthful practitioner should require the same rate of payment for inexperience and less ability.

The insistence on one universal rate for all architects is a suicidal policy. The public is apt to appraise a man at his own valuation. It loves to pay high prices for the services or the productions of the best men, and would be delighted to pay the architect who is a Royal Academician in the same ratio to the fair wages of his juniors that it does in the case of painters.

When the Royal Institute receives its new charter, the schedule of charges is one matter that requires amendment, and it should be made clear to which end of the architectural profession the 5 per cent. applies, so that all grades of architects may, according to their ability and position, receive their "fair wages."

Mr. George Banks Rennie, of Denford, Hungerford, Berks, and of Lowndes Street, Belgrave Square, engineer and shipbuilder, of G. Rennie & Co., of Greenwich, a member of the Institution of Civil Engineers, who died on November 15, aged seventy-six years, left estate of the gross value of 96,771*l.* 15*s.* 7*d.*, of which the net personalty has been sworn at 85,775*l.* 14*s.* 7*d.*

AN ANCIENT IRISH FORT.

THE Grianan of Aileach, which is scheduled in the Ancient Monuments Protection Act of 1882, was vested in the Board on November 9, 1904, by Lord Templemore, and initial repairs have been undertaken by the Commissioners of Public Works, Ireland. A large portion of the walling had fallen down to within 5 or 6 feet of the ground on the south-eastern face. The wall here was 16 to 17 feet in height, and it has been carefully rebuilt with the fallen stones in dry masonry to its original height, preserving the widths of the steps formed in the thickness of the walling and following exactly the original lines as indicated in the adjoining work.

The parapet wall at the top had been greatly injured and almost entirely thrown down by persons visiting the place. During the years 1870-5 a local resident, Dr. Bernard, had at his own expense rebuilt a great portion of this ancient stone fort, the walls of which at that time had become greatly dilapidated. He took the precaution of marking in black colour the walls at the level at which he commenced the rebuilding. The galleries or passages in the thickness of the walls were undisturbed save in a few places where the covering stones were displaced. The lintel covering the entrance, which had fallen, was re-erected. The work done by Dr. Bernard was in keeping with the untouched work then remaining, and is of the character of similar work to be seen here and elsewhere in Ireland.

The principal dimensions of the cashel or stone fort are as follows:—Diameter internally, 77 feet 3 inches east to west, and 76 feet 6 inches north to south; walls 13 to 14 feet wide at base, averaging 16 feet in height. The entrance faces due east, and is 4 feet 1½ inches wide at bottom, and 3 feet 1½ inches at top, and 6 feet 1 inch in height.

There was no spring, but a small well, which collects surface water only. It was 20 inches in depth, and was probably a cooking pit. Adjoining it is an opening through the wall measuring 18 inches wide and 14 inches high, narrowing to the outside face to a width of 9 inches at the bottom, 7 inches at top, and 1 foot in height. There are no traces of the stone huts which are believed to have occupied a portion of the interior.

According to the seventy-sixth annual report of the Commissioners of Public Works, Ireland, there are several cashels or stone forts of like character vested in the Board such as those on the Aran Islands, county Galway, viz.:—The Great Fort on Inisheer, the Forts of Conor and Mothar Dun on Inishmaan, and the Forts of Dun Ængus (a cliff fort), Dun Eochla, and Dubh Cathair on Inishmór, also at Inishmurray, county Sligo, where the structure was afterwards devoted to ecclesiastical uses; at Kilcolman, in the same county, and Dunbeg Fort (a promontory fort), and Staigue Fort, county Kerry. There are the remains of similar forts and stone-roofed huts at Kilcashel, parish of Kilmovee, county Mayo, which have not been vested. These ruins represent the most ancient type of construction in stone known in Ireland, and are composed of stones laid dry without any cementing material.

Of the original date of the erection of the Grianan there is no record, but there are frequent references to its attempted destruction. The earliest reference to its occupation is in the Tripartite Life of St. Patrick, said to have been written in the sixth century, where Aileach is spoken of as the remotely ancient seat of the Irish kings before St. Patrick's time, and in the Book of Lecan there is a list of its forty-four kings from the fifth to the eleventh century.

In 1101 Murtogh O'Brien, King of Munster, it is said, led a great army into Inishowen and "demolished" Grianan in revenge for Cenncora, which had been razed and demolished twenty years before by Domnal O'Lochlain, and Murtogh commanded his army to carry with them from Aileach to Luimenech (Limerick) a stone for every bag of provisions which they had. In 1599 O'Donnell ravaged Clare, and took Ennis, avenging the sack of Grianan of Aileach five centuries before.

In a volume issued by the Ordnance Survey Office entitled "Memoir of the City and North-Western Liberties of Londonderry, Parish of Templemore," published in 1837 ,the Grianan of Aileach is described as it stood in the year 1835.

The further descriptive and historical notes of the structure which follow are chiefly taken from the publication referred to:—

The Grianan of Aileach is situated in the county of Donegal, about 7 miles from Derry, on the summit of a hill 802 feet high. The ascent on the eastern or Derry side is tolerably gradual, but near the top it assumes a more precipitous character, and it terminates in a circular apex which commands an extensive and beautiful view. Formerly an ancient road between two ledges of natural rock led to the summit. Three concentric ramparts surrounded the cashel or keep of the fortress. These external ramparts, which are all in a state of great dilapidation, appear to have been formed of earth mixed with uncemented stones. They are of an irregular circular outline, consequent upon their adaptation to the form of the hill which they enclose, and ascend above each other in successive steps or terraces. Between the third or innermost rampart and the cashel the road diminished considerably in breadth, and diverged slightly to the right, and this approach was strengthened by a wall on each side, of which the foundation stones alone remained.

The cashel, though in a more perfect state than the external ramparts, was a mere ruin. The circular wall enclosed an area 77 feet 6 inches in diameter, and was about 6 feet in height, varying in breadth from 15 feet to 11 feet 6 inches, or averaging above 13 feet. This wall is not quite perpendicular on its external face, but has a curved slope, or inclination inwards, like Staigue Fort, in Kerry, and most other forts of the kind in Ireland. From the quantity of fallen stones, which form a glacis on either side, it must have been at least twice, and was possibly four times, its present altitude. At the height of about 5 feet from the base on the interior face of the wall, the thickness is diminished about 2 feet 6 inches by a terrace, the ascent of which was by staircases, or flights of steps, increasing in breadth as they ascend and situated at each side of, but at unequal distances from the entrance gateway. There was originally a succession of three or four such terraces, ascending to the top, or platform, of the wall. On each side of the entrance gateway there are galleries within the thickness of the wall, extending in length to one-half of its entire circuit, and terminating at its northern and southern points. These galleries are in places 5 feet high, and have sloping sides, being 2 feet 2 inches wide at bottom, and 1 foot 11 inches at top; they are covered by large stones, laid horizontally.

In the southern gallery, and near its eastern termination, there is a small rectangular recess with a seat about 18 inches high. On each side of the entrance passage there is a recess, probably for the purpose of receiving the leaves of a folding door, as their united measurements are equal to the breadth of the passage.

The circular apex of the hill contains within the outermost enclosure about five and a half acres, within the second about four, within the third about one, and within the cashel about a quarter. The masonry of this great work is exactly similar to that of many other Irish cashels or cahirs. The stones, which are of the common grey schist, are of polygonal forms, adjusted to fit each other and wholly uncemented. They average about 2 feet in length, and it is quite evident that they have been in many parts squared with the hammer, but not chiselled. This, as already stated, is most apparent in the angles, &c., of the entrance passage; but in the exterior face of the building the stones are much more rounded, or worn at the edges, and indicate from their state of decay, as well as from the lichens with which they are overgrown, a very remote antiquity.

In the centre of the area of the cashel there were remains of a small building measuring 16 feet 6 inches by 14 feet 3 inches. The walls, 2 feet thick, and not more than 2 feet high, were constructed with mortar. The antiquity of this building is doubtful, and the probability is that it was erected for a chapel during the severe administration of the penal laws. It was certainly used as a chapel until near the end of the eighteenth century, when a chapel was erected at Burt. There are no other vestiges of habitations either within the cashel or its external ramparts. Between the third and fourth walls there is a spring well, which when discovered was covered with a large stone, and between the second and third walls there is a small mound having around it a circle of ten large stones, laid horizontally and converging towards the centre. When the mound was opened shortly before 1835, nothing was discovered in it that would throw light on the purpose of its erection.

The Grianan of Aileach was one of the most remarkable and important works of its kind ever erected by the ancient Irish, the palace of the Northern Irish kings from the earliest age of historic tradition down to the commencement of the twelfth century, and consequently such careful examination of its vestiges as should help to convey a clear idea of its original form, structure, and extent, would give the best evidence now obtainable of the style of military

Digitized by Google

building known to the Irish at the remotest period of their history.

That Grian, or the sun, was an object of worship among the Pagan Irish is not to be denied, but that the word Grianan was ever applied to denote a temple of the sun, or a temple of any kind, no authority has been as yet adduced or found, while there are abundant evidences that it was constantly used in a figurative sense to signify a distinguished residence, or a royal palace. It is thus explained by O'Reilly:—"Grianan, a summer house, a walk arched or covered over on a hill for a commodious prospect (a balcony)—a royal seat."

Numerous examples might be quoted of the application of this term to the palace or royal fortress of the Northern Irish kings. Of this fact two instances may here suffice. Both these occur in the poem of Cormacan Eigeas, the bard of Murtagh of the Leather Coats, written in the year 939:—

O Murtagh, son of noble Niall,
Thou hast taken the hostages of Inis-Fail,
Thou broughtest them all to Aileach,
Into the splendid Grianan of horses.

Connor, son of Teige, the bull-like,
Puissant, arch-king of Connaught,
Came with us without a bright fetter,
Into the green Grianan of Aileach.

In all the Irish histories the place of the Northern Irish kings is designated by the name of Aileach simply, or Grianan-Ailigh, Aileach-Neid or Aileach-Fririn, and its situation is stated to have been on a hill in the vicinity of Derry. The signification of this name, Aileach, independently of its attendant epithets, is obviously "stone house or habitation," and it is so explained by Michael O'Clery, the Chief of the Four Masters, in his glossary of ancient Irish words.

The following historical notices relative to its demolition appear in the various Irish Annals:—

674 Aileach-Fririn was destroyed by Finsneachta, the son of Donchadh (King of Ireland).

937 Aileach-Fririn was demolished (according to the Four Masters plundered) by the Danes.

1101 Murtagh O'Brien, King of Munster, at the head of the forces of Leinster, Ossory, Meath and Connaught, demolished the Grianan of Aileach, and he ordered his army to bring from Aileach to Limerick a stone of the demolished building for every sack of provisions which they had with them.

This is the last notice of Aileach as a royal residence to be found in the Irish Annals, and it appears never after to have been thoroughly rebuilt.

ELECTRICITY AS APPLIED TO HEATING AND COOKING.*

THE application of electricity to heating is by no means a modern invention—that is, as electrical matters are judged. There is a record of experiments of this nature carried out by Sir William Harris in 1827, but it was not until fourteen years later that Joule discovered the law known by his name. Most of the early experiments were with respect to furnaces for the reduction of oxides. In 1885 a book was published by "Hospitalier," entitled "Domestic Electricity," which dealt with the ignition of oil and spirit lamps by means of platinum wire brought to red heat by primary batteries.

Three or four years later the first company for the manufacture of heating apparatus for domestic purposes was formed. Several companies had previously made attempts, but it remained for the "Carpenter Electric Heating Corporation" to place articles of any reliability upon the market. Since this first attempt (one might venture to call it the first attempt without any great deviation from the truth) great strides have been made both in efficiency of operation, reliability, and lessening of cost of production. The essential features of effective and satisfactory cooking and heating apparatus are:—

1. The operation to be carried out as rapid as its limitations will permit. 2. The highest commercial efficiency possible—i.e. with the water standard. 3. There must be no smell or dirt.

A word as to limitations. Most operations, except the boiling of water, form their own limitations, for if the operation is carried out too quickly the articles will burn; after that the chief is the "coefficient of conduction," whereby the heat capable of being generated is limited by the rate at which it can be carried away therefrom and used for useful purposes, otherwise the wire or metal film, according to construction, will be fused.

Another consideration is the current flow required to obtain high rates of heating. Corporations and supply companies generally limit the current set in flow by the closing of any one switch; this necessitates the employment of a rheostat or some other suitable arrangement. In addition to this increased cost there is further capital outlay in heavier mains, switches, &c.

Speaking generally, there are two principles of heat generation, electrolitic and hot wire. The latter may be subdivided into the following:—(*a*) Incandescent lamps; (*b*) hot wire coils; (*c*) hot wire coils in enamel; (*d*) hot films; (*e*) hot iron plate (transformer method). The author gave a detailed account of each.

He next reviewed some important facts in connection with the heating of air.

The thermodynamic inefficiency of prime movers for the generators of electricity greatly reduces the efficiency of electric warming apparatus, though this disadvantage is not quite so great as is generally believed. For example, with a small room of 1,500 cubic feet capacity it should be theoretically possible to raise the temperature of the air in the room from 32 to 60° Fahr. with about 200 watt hours. If the air in such room is changed twice an hour, a radiator consuming 400 watts would be theoretically necessary to maintain a temperature of 60°, the temperature of the outside air being as low as 32° Fahr. Now, if an electric radiator consumes 1 kw., its efficiency for air warming will only be about 40 per cent., and it is quite clear that it must be possible to improve the efficiency of the apparatus to at least, say, 70 or 80 per cent., and this, in fact, can be done. The capacity of an electric radiator for warming air depends principally on the amount of convected heat given out by the apparatus, and this percentage of convected heat is in inverse ratio to the temperature difference between the apparatus and the surroundings. If the electric radiator has a temperature difference above the surroundings of 1,200° Fahr., the percentage of radiant heat emitted by the apparatus will be approximately 95 per cent., so that only 5 per cent. of the heat will be used for direct air warming or convection purposes. The radiant heat emitted by the apparatus will impinge upon the walls of the room, thereby warming these walls, and a great part of the heat will be dissipated on the outside of the walls. The percentage of heat received by the walls and dissipated on the outside depends upon the heat conductivity of the walls, and in the case of very thin walls or windows this may be very great indeed. At a temperature difference of 600 to 700° Fahr. the percentage of radiant heat given out by the apparatus is still about 70 per cent., and only 30 per cent. is used for direct air warming; and at a temperature difference of 100°, however, the percentage of heat used for direct air warming becomes very great, and it can be safely stated that an electric radiator having an outside temperature of only 100° Fahr. above the surrounding air can by judicious design and construction be made to have an efficiency of 70 to 80 per cent. for direct air warming purposes.

The efficiency of the apparatus will be greatly assisted if the covering of the wall is of such a nature as to retain a stagnant layer of air close to the walls, which effectively insulates the wall from the heated layers or currents of air moving along the wall and thereby prevents the heat of the air in the room from being imparted readily to the wall itself.

If the electric radiator produces a great percentage of radiant heat this stagnant layer of air is no insulator, because the radiant heat will pass through it without incurring appreciable loss. Electroyl radiators have an efficiency of 70 to 80 per cent. for direct air warming purposes, and will therefore bring the electric heating within the reach of everybody, provided that the cost of electricity does not exceed 1*d*. per unit.

In some types of electric radiators the working temperature is so high that the greater part of the heat is given off as radiant heat. With such radiators the air can only be heated indirectly—that is, by coming in contact with bodies some certain distance away from the radiators. The intensity of these heat rays, as is also well known, decreases with the square of the distance.

Reference was then made to some comparative tests carried out at the Thomas E. Clarkson Memorial School of Technology, U.S.A., by Miss C. D. Fraser, of cooking by

* Abstract of a paper read before the Liverpool and District Electrical Association, at the Common Hall, Hackins Hey, Liverpool, by Mr. S. R. Gibbon.

Digitized by Google

electricity, coal, gas, gasoline and kerosene, which showed that with electricity at 1*d.* per unit there is much in its favour.

The author commented on the pushing policy of the Marylebone Borough Council in respect to electric heating in cooking, and hoped that other supply companies and municipalities would follow their example.

QUARRYING IN BELGIUM.

BELGIUM is rich in various kinds of stone and marble. The quarrying industry employs over 37,000 men, and its annual output exceeds 2,500,000*l.* The most important quarries are in the provinces of Hainaut, Liège and Namur, these furnishing seven-eighths of the total stone quarried in Belgium. The products are freestone, limestone and paving-stone. The American Consul at Liège says that the blue stone is the best known, and is serviceable for building and ornamental sculpture, being probably the most important product of this class of quarries. The quarries of Soignies, Ecaussines and Sprimont are the most noteworthy in this connection. These are provided with powerful modern machinery, and employ a large number of workmen. They have also attached to the quarries apprentice workshops, where young workmen receive practical and theoretical training in stone-cutting and sculpture. The quarries of Belgium furnish a great variety of marbles, which stand rather high in the market. Of black marbles there are three distinct groups, the first furnishing a marble much in demand even outside Belgium, which is used in the manufacture of clock cases and mosaics. The "Noir fin de Golzinnes" is valued on account of its purity, the high polish it is capable of receiving, and its adaptability to the carver's chisel. The second group produces a marble that is soft and easily carved, and the third is a deep black, close-grained stone, serviceable for flooring slabs, plinths, window facings and fireplaces. There are many varieties of red marbles, which are used mainly in large work, such as altars, columns, fireplaces and window sills. Blue marble, so-called, is used generally for decorative work and paving. The "florence lilas" is very much in demand. The marbles most used in Belgium are the Sainte Anne blue, the red mottled, the Belgian black and the "granit." The blocks are often shipped in the rough, but it is more customary to finish them at the quarries, the workmen enjoying a reputation of being especially clever in this class of work. The production of porphyry paving-stone blocks, sandstone and calcareous stone is second in importance in Belgium. The slate quarries of Amblere have been worked from time immemorial as material for razor hones. The stones are cut in parallelopipeds, the under side of which is composed of slate, while the upper surface consists of the sharpening stone. The stone is exported chiefly to Germany, but some goes to the United States. Limestone is found generally distributed throughout the country. Limekilns are plentiful, and are confined to no particular locality, although those of the Provinces of Hainaut, Namur and Liège are those only worthy of being mentioned as industrial enterprises. Potter's clay is found generally throughout the country, that found on the Rupel and in the neighbourhood of Courtrai being used in the manufacture of tiles, drainage pipes, paving blocks and bricks. Chalk is extracted in large quantities at St. Vaast and at Trivieres.

BIRMINGHAM UNIVERSITY.

THE new University buildings at Bournbrook have not escaped severe criticism, both professional and lay. From the Bristol Road they appeared to one critic as "an unintelligible mass of sprawling brick, dominated by an imitation of the Mangia Tower in Siena," and from the University Road as "a long stretch of featureless subsidiary buildings which might very well be mistaken for a factory." Fault is also found, according to the *Birmingham Post*, with the campanile, which, this critic complains, "is dumped down in the middle of the courtyard, so that more than half its height is hidden by the library, and only the excessively tapering top is seen in sheer fore-shortening. The general effect is almost comical, and it is difficult to conceive a worse-planned building. It is fairly obvious that the architect had been impressed by Bentley's Westminster Cathedral. He has taken from him the Byzantine domes and the lofty campanile, but, whereas Bentley adhered to the Byzantine tradition in the planning of his noble edifice and displayed his originality in the invention of beautiful details, the architect of the new Birmingham University abandoned the principle of growth so important in Byzantine architecture and merely borrowed certain disconnected ideas for his sprawling, disjointed plan." Much of this criticism is vitiated by two facts which, apparently, have been either ignored or lost sight of. The first is that the new buildings are mainly utilitarian in design, and the second, that in their present state of incompleteness no sound opinion can be formed as to the ultimate appearance they will present. Not till then will the unity and homogeneity of the design be apparent. In the existing inchoate state of the buildings common fairness dictates that judgment should be reserved until that remote, and it must be confessed somewhat problematical, period, when the designs of Sir Aston Webb and Mr. Ingress Bell have been fully carried out.

In the meantime, the close of another year brings with it the task of again recording the progress made in this great work. Its magnitude makes that task no easy one. The work grows so slowly, almost imperceptibly, that even those engaged upon it confess difficulty in stating precisely what progress has been made in twelve months. But what, as a matter of fact, has been accomplished in that time has been the completion of the exteriors of the Harding Library and the chemistry and physics blocks, the carrying up of the tower to the belfry, the erection of an observatory, and substantial progress in laying out the terrace and the grounds. Of the two blocks named, that to be devoted to chemistry is the lesser advanced, but though the scaffolding has not yet been removed it may be said to be finished so far as the exterior walls are concerned.

The designs, readers may be again reminded, are for a series of buildings arranged in the form of a semi-circle, with University Road, which runs practically parallel with Bristol Road, as the diameter. Radiating from the centre to the circumference of this semi-circle there will be ten blocks, and the size of each will be, roughly speaking, equal to that of the Birmingham town hall—a statement which brings the vastness of the scheme vividly before the mind. Of these ten blocks five are at present erected, and three—Blocks A and B devoted to electrical, mechanical, and civil engineering, and Block C to mining and metallurgy—have been in occupation for a considerable time. The two other blocks are those set apart for physics and chemistry. They stand at right angles to the main entrance. This leaves two blocks to be erected between Block C and the physics block, and one between Block A and the chemistry department.

It is upon the tower (the contract for which is being carried out by Messrs. Waring & White, London) that most progress, at least to the outsider, appears to have been made during the past year. This tower, which is built of Accrington red bricks, with Darley Dale stone dressings, has now been carried up to the stone machicolations upon which will rest the balcony running round the belfry walls. When completed, this tower, if only by virtue of its height from the level of University Road, will be a conspicuous landmark for miles round. It rests on a solid rock foundation 50 feet square, and will rise from the ground level to a height of 325 feet, being surmounted by a graceful spire. The clock, which is to be supplied by Messrs. Joyce, of Whitchurch, will have a face 17 feet 3 inches in diameter, and the belfry will contain five bells, weighing five tons each. The tower will contain ten floors, and they and the balcony will be reached by a lift. This tower stands immediately behind the Harding Memorial Library, erected in arches above the main entrance and in front of the entrance hall, over the door of which are statues representing poets, musicians, scientists, and philosophers. The early months of the year were devoted to giving the finishing touches to this hall, the floor of which is in Dove Pentelikon and Sicilian marble, while the walls are adorned with Breche Violette marble columns with grand antique bases and skirtings and statuary caps. The columns support a circular promenade having gilded railings. Above is the dome with its whispering gallery. The dignity of the entrance hall is in keeping with the general scheme, and forms a fitting introduction to the great hall opening out of it. Stately in outline and impressive in its proportions this hall is unquestionably one of the most striking features of the buildings. It has been in use for over a year for examination purposes, and has since been enriched by a beautiful stained-glass window at the south end, the gift of Sir John Holder. At the present time the organ is being fitted up, a peculiarity of the instrument being that the pipes are divided into two parts, fixed on each side of the hall. The mechanical power necessary for the playing of the organ will be supplied by an electrical motor. On the east and west sides of the hall are emer-

Digitized by Google

gency exits leading to the courtyards. Running round three sides of the hall is a recessed gallery constructed to form a kind of colonnade. The Harding Library was practically finished last year, so far as the exterior was concerned, and the work in hand now consists of supplying the internal equipment.

Considerable progress has been made in the laying-out of the grounds, and the site generously presented by Lord Calthorpe is being gradually reclaimed from chaos and confusion to something like ordered design. A terrace 20 feet wide and 1,200 feet long, having centre and side rock-faced bastions of Darley Dale stone, is being constructed parallel with the Bristol Road, and when this is finished will add considerably to the general effect of the buildings on the south side. From the east end of the terrace a winding road will lead down to the Bristol Road, where imposing ornamental gates will be erected at a point opposite Bournbrook Road. At one side of these gates a porter's lodge will be built, the foundations of which are now in hand. From the centre bastion in the terrace a flight of steps will lead to the lower level path, from which more steps will give access to the playing fields, twenty acres in extent, also the gift of Lord Calthorpe. Other work, either completed or in hand, is the erection of the boundary wall along the Bristol Road. On an average 250 men have been and are employed on the buildings, and it is satisfactory to be able to record that during the past year no accident of a serious character has occurred. The whole of the work is being carried out under the supervision of Mr. Henry Gray, as clerk of the works.

Dealing with the work of the University, it may be said that the departments of civil, mechanical, and electrical engineering, and also those of metallurgy and mining, have already been working for three sessions, and as the buildings for these departments were completed, and the initial equipment supplied, little change in these directions has occurred during the past year. In the civil engineering section good progress has been made with the arrangements for the testing of cement, and the new 100-ton vertical tensile testing machine has been brought into regular use. In each section the departmental libraries are properly organised, and are receiving additional volumes, while the metallurgical museum has been enriched by the addition of numerous specimens. But the chief improvements are probably those dealing with the comfort of the students and staff.

THE MAKING OF CITIES.

PROFESSOR PATRICK GEDDES, University College, Dundee, delivered a lecture on "The Making of Cities: Past, Present, and Possible," in Aberdeen Art Gallery last week.

Professor Geddes said they might wonder why he took so vast a subject for his lecture, and said he would introduce himself as being in a way the editor of an encyclopædia of which the name, if it were finished, would be—and for that he could not hope—"The Encyclopædia Civica." It would be a study of cities in their past and present states, and of their people also, and it would try to bring together a splendid literature of cities, to gather in picture and indeed in gallery the presentment of their beauty, and would seek to inspire the citizens of each city to some sense of the possibilities and responsibilities of their future. They all more or less existed in cities, and their holidays were largely spent in visiting them as much as country scenes, but little was known of cities. He could not name a book which would give a discussion of cities as a whole. There was a great deal of history, but it was largely concerned with nations or persons, but the city was still largely overlooked. They must recognise they were not only individuals and not only cities, but great human groups or hives. To know cities was one of the essential steps towards knowing humanity and social science. As in natural science so in civic science, they must begin by going to see examples. Modern American cities, such as Washington, Boston, Buffalo, Yale, and Harvard may be taken as types of city planning, of park improvement and university development. The extension of public parks which was proceeding in America was to be heartily approved, as well as the system of linking up those pleasure grounds with boulevards so as to bring the parks within reach of all the inhabitants of those great cities. Professor Geddes then returned to the modern British city, with its slums and jerry-built houses, while as examples of better things, however, the Glasgow Art Gallery and National Exhibition of 1901 were contrasted favourably with the recent Franco-British Exhibition, which, although on a larger scale, had been visited by fewer people, and had been less successful than that of Glasgow. As an instance of the failure of even the best municipal intentions, without artistic guidance, there was exhibited the triangular bronze pediment recently erected by the Edinburgh Corporation on their magnificent new hospital. The modern question as to town planning was next gone into, with illustrations from German towns and cities, and Professor Geddes showed that town planning was not a new thing, but had been a lost art for a few years. As an example of a garden city, Hampstead was taken as the best up to date. In the scheme the design had followed the natural condition of the ground, making the hills neither too sudden nor too steep. Hampstead, with its famous heath, had enormous possibilities, and with an enterprising mayor there was every indication of the best being made of the town. Professor Geddes described Aberdeen as a regional capital. In his London lectures he had referred to Dundee as the saddest and Aberdeen the finest city in these islands. He urged the community to secure the preservation of Old Aberdeen, with its ancient beauty and attractiveness, and to prevent Rubislaw Den being spoiled; while he also spoke of Aberdeen as the leading municipality in the matter of street tree planting. The practical problem before Aberdeen and other cities was to prepare for the Town Planning Bill, as much yet required to be done to obtain the best from the city. He remarked upon the dangers of some plans, and the possibilities and advantages of others in the matter of health and economy as well as beauty. As the most practical means of preparing for town planning and of avoiding the risks of too hastily prepared plans, a method was outlined by Professor Geddes as convener of the cities committee of the Sociological Society, which had already been arranged at Leicester, Chelsea, Richmond, and other towns. Richmond had for some time been the pleasure-ground of London people, but now the motor-car took them further afield. Chelsea, although more a seat of industry than Richmond, also possessed much beauty. The general idea of the exhibitions which had been held at those places was to bring together the resources of the antiquary, the archæologist and historian of the past with models, plans, and pictures all combined and with views of photographic surveys of the present with its beauties and blemishes. They should also add to those, as far as possible, a survey of the actual social conditions such as had been made by Mr. Booth for London, or on a similar and more convenient scale by Mr. Rowntree for York, Miss Walker for Dundee, or Mr. Arthur Sherwell for Edinburgh. The past and the present being thus represented, the possible improvement of the future had next to be prepared for, and towards that two distinct lines of work were necessary—first, to bring together good examples of town improvements and city design from Germany, America, and other countries as well as our own, so as to educate public opinion and call forth architectural skill and public spirit. Finally, with all that knowledge it should become possible for many architects and others to make useful suggestions towards possible improvements on this or that quarter of the town, and in such ways, by means of those exhibitions, the whole community would be aroused to a clearer sense of its common interests and its possibilities. The advantage, too, to the art gallery, library and museum of such a co-operation with the city authorities and the citizens generally was also pointed out, and the lecturer concluded with a strong plea for the preparation of such an exhibition.

The French Minister of Marine has offered to the Louvre authorities a collection of sculptured works by Puget which were recently at the Franco-British Exhibition.

Mr. William Milner Fawcett, M.A., architect, Cambridge, died at his residence at Cambridge on Sunday at the age of eighty-six. He was born near Leeds. He began practice as an architect at Cambridge in 1859. He obtained his F.R.I.B.A. in 1866, was member of Council from 1871 to 1873 and from 1884 to 1889, and was vice-president from 1896 to 1900. He was a county surveyor for Cambridgeshire 1861, and diocesan surveyor for the diocese of Ely 1871. Among his architectural works are the Cavendish Laboratory, additions and alterations to King's, Queens', Emmanuel, Peterhouse and other colleges, the training college for women at Cambridge, additions to Addenbrooke's Hospital, over seventy county mansions and County Council buildings, and the building and restoration of about fifty churches. Mr. Fawcett was for many years an enthusiastic volunteer.

NOTES AND COMMENTS.

THE third quarterly issue of the *Architectural and Topographical Record* has now appeared, somewhat belated. The parishes with which the present number deals are Boveney, in Buckinghamshire; Tyneham, Steeple, and Kimmeridge, in Dorsetshire. The historical and archæological data are, as usual, well treated, whilst of architectural interest there are measured drawings of a pleasing little two-light fifteenth-century window and seventeenth-century screen, pulpit and pews in the chapel of St. Mary Magdalene at Boveney; a seventeenth-century pulpit in the parish church of St. Mary at Tyneham; and some late sixteenth and early seventeenth-century details from Tyneham House, which is described as "the finest example extant of the sixteenth-century manor houses of the Isle of Purbeck." One of the most interesting things in this issue is the sketch of a chalice with paten cover, bearing date 1574, in the church of St. Michael at Steeple.

THE suggestion of Mr. J. LANDFEAR LUCAS that Portland Place should be extended across Regent's Park to the foot of Primrose Hill, so as to form a stately processional avenue, if inexpedient when Portland Place was laid out, does not seem to have good grounds for its realisation at the present day. London hardly wants a processional avenue from the Langham Hotel to Primrose Hill, or in the converse direction. The tide of fashionable life has drifted so far west that even the lengthening of the wide roadway would scarcely attract carriage folk to these comparatively unknown regions. The idea of taking away part of the park and turning the land bordering on the new processional avenue into building plots is objectionable not only on account of the injury to one of the "lungs" of London, but because Regent's Park was originally a swamp, and is still one of the surest localities in the metropolis for the study of mist and radiation fogs. Of course, it is a corollary of the suggestion now made that the projected Shakespeare memorial should be put on the top of Primrose Hill, instead of, as at present intended, at the Euston Road end of Portland Place. True though it is that the magnificence of Portland Place is lost in a backwater of London's life, if one were proposing to Haussmannise, it should be southward rather than northward, so as to extend this stately avenue, that at present leads from nowhere to nowhere, until it joined Piccadilly Circus. This would hardly fit in with the improvements that have been determined, and partly commenced, in the Regent Street Quadrant and Piccadilly Circus, so that in the present temper of London's inhabitants and London's governors this suggestion is quite as Utopian as the idea of extending Portland Place to Primrose Hill.

THE Institution of Heating and Ventilating Engineers has opened a competition for its members and for employés of any bona-fide heating and ventilating engineer in the British Isles, and is offering prizes of 25*l.*, 5*l.*, and 2*l.* The subject of the competition is the preparation of a complete scheme for heating and hot-water supply suitable for a general hospital, the plans of which have been prepared by a member of the Council of the Institution. We hope these plans have been prepared merely for this competition and not for execution, as they are anything but admirable as an example of hospital planning. This, of course, does not matter if they are merely a basis for the present competition; indeed, they would give all the more scope for skill in the competitors, particularly if the ventilation of the building were included as part of the problem.

IN the future history of the Crystal Palace the fifty-ninth general meeting will mark an important epoch, for it gave approval to a Bill being promoted by which State assistance is asked to permit of its continued existence. The private Bill, which was lodged last week, states that the company have been unable to issue the 75,000 1*l.* preference shares authorised by Parliament in 1906. The Bill proposes to empower the Public Works Loan Commissioners to lend on mortgage 50,000*l.* for the repair and improvement of the structure and such a further amount "as may be requisite" for the redemption of all or any part of the existing 495,000*l.* debenture stocks. The loans made by the Commissioners are to be repaid within sixty years and to bear interest at a rate not exceeding 3*l.* 15*s.* per cent. Power is sought to enable the company to prepare schemes for "the promotion or extension of the usefulness of the Crystal Palace and the grounds thereto belonging for any purposes beneficial to the public." These schemes are to be subject to the sanction of the Board of Trade. Public opinion showed at the recent Mansion House meeting that it would be unwilling to allow the Crystal Palace to become a mere memory, even if it has to be supported out of the national exchequer. It has been officially stated that a sum of 100,000*l.* would place the company on a firm footing.

THE value of hypochlorite of lime, or "chloros," as a sterilising agent for waters polluted by organic impurity, which was proved at Maidstone and Lincoln in our own country, with the Elbe water at Hamburg and the Seine water at Suresnes, has further proved its utility in the purification of the water of Bubbly Creek, or Stock Yards slip, as it is officially known, of the Chicago River, and a full account of the detail of its application is appearing in our contemporary, the *Engineering Record*.

THE Architects' Technical Bureau has issued to its subscribers the first folio of Standardised Manufacturers' Circulars, but its value to architects is not very apparent, as only a very few manufactures are included, and these neither very important nor, for the most part, very novel. Although the circulars bear the imprimatur of the Bureau and profess to have obtained the approval of the advisory committee, it is difficult to understand to what this extends other than to the form of publication, as it is expressly stated that no tests have been made.

ILLUSTRATIONS.

DESIGN OF PROPOSED NEW MOSQUE FOR LONDON.

THE illustration is from a bold pen-and-ink drawing made by Mr. W. I. CHAMBERS.

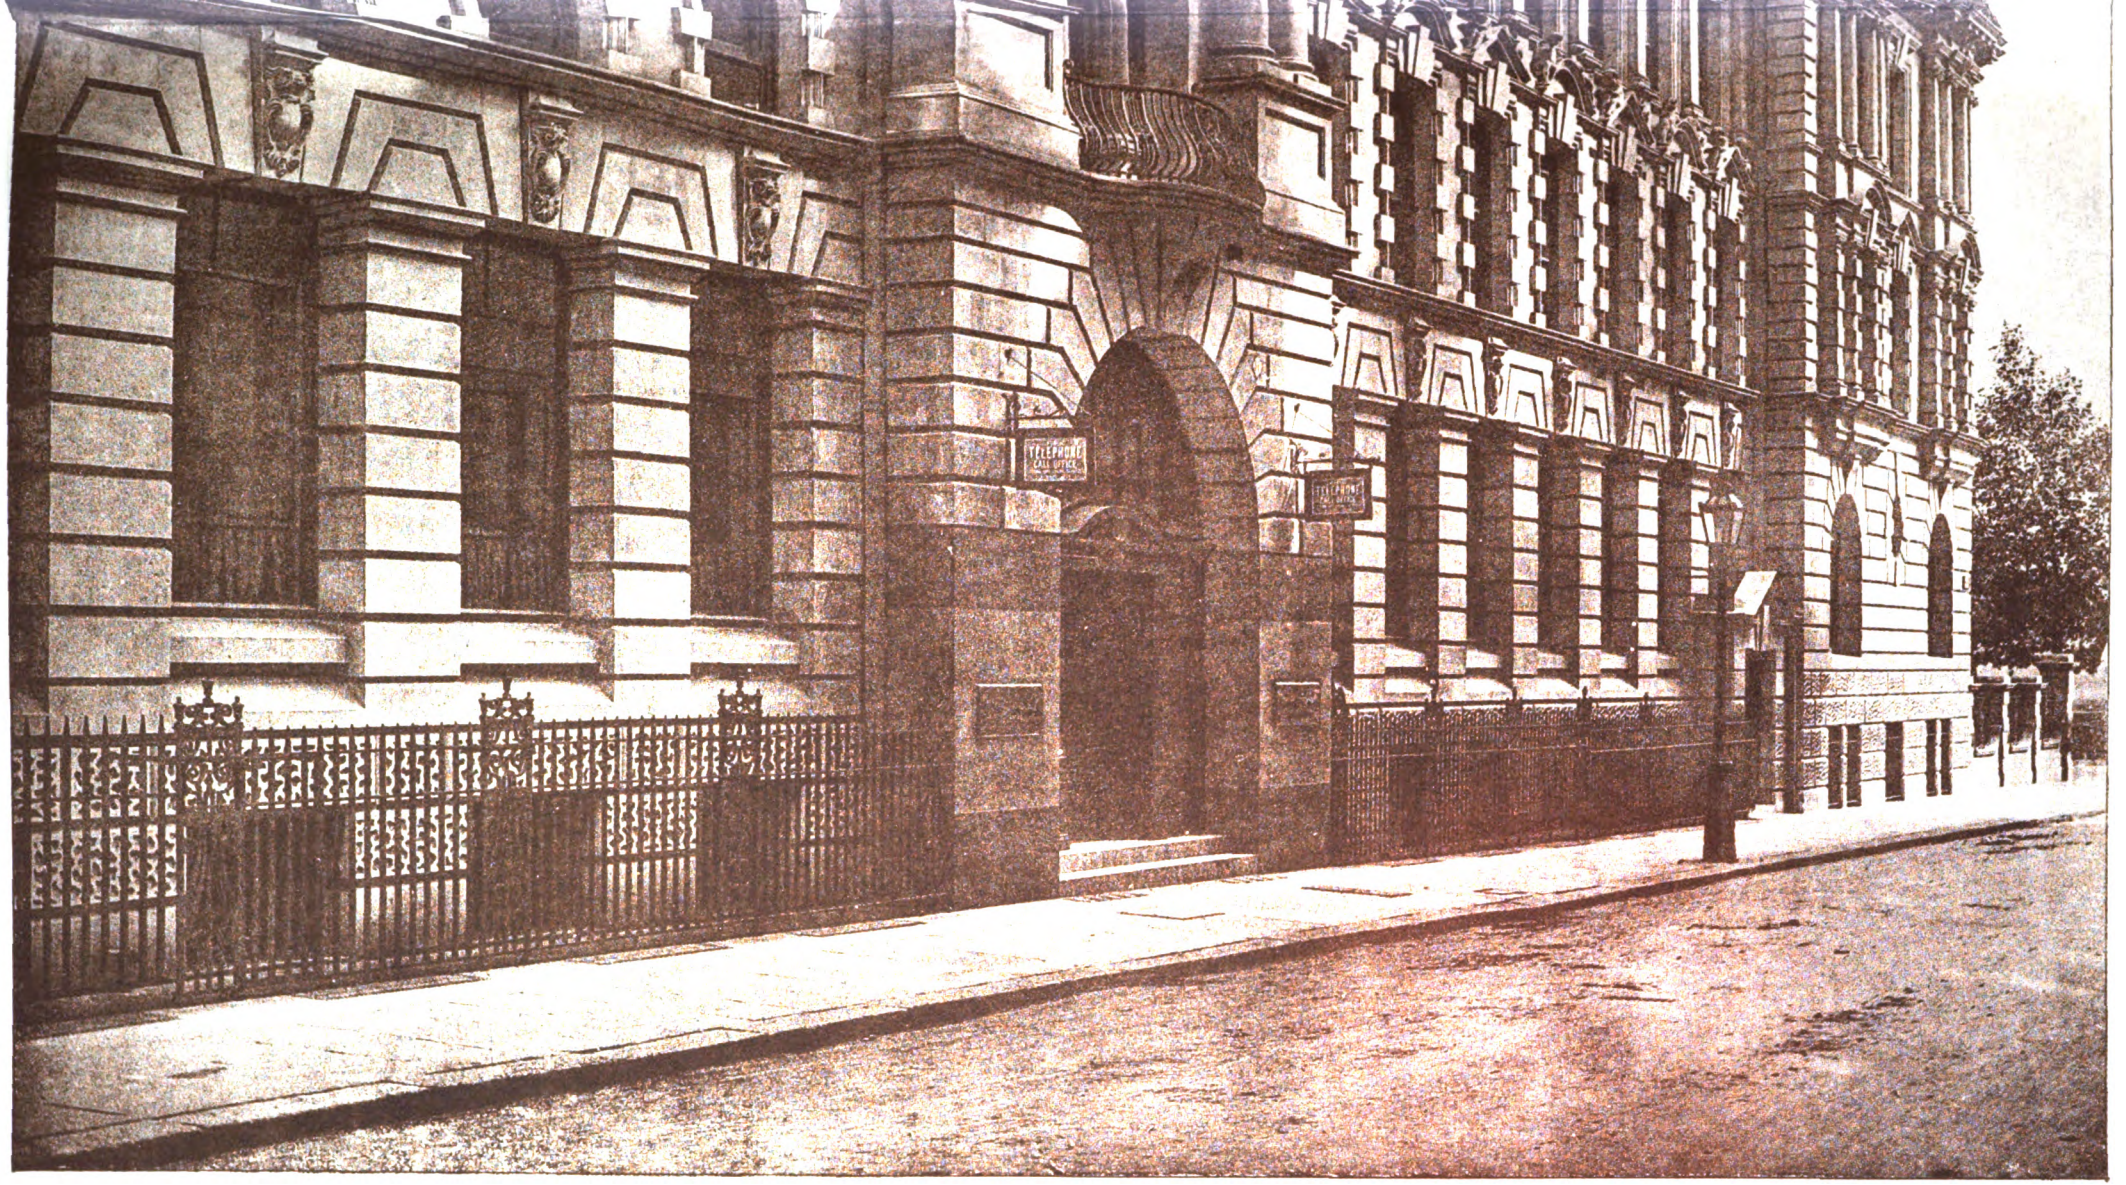
HARLEY HOUSE, MARYLEBONE ROAD, N.W.

THIS fine building, consisting of high-class residential flats, occupies a fine open position on the Howard de Warden Estate, and faces Marylebone Road, opposite Harley Street. The main frontage faces south and is set back 50 feet from the roadway, the intervening space being laid out with ornamental gardens. The main elevations are in Hartham Park and Portland stone, and the construction is fireproof throughout, while there are in addition fire-escape stairs to each flat. Each block has a fine entrance hall panelled in mahogany. The main staircases are in stone, handsomely decorated, and fitted with a passenger lift, giving access to the upper floors. Electric light and electric bells are fitted throughout. The construction of the building was carried out by Messrs. J. SIMPSON & SONS, of Paddington Street, under the supervision of the architects, Messrs. BOEHMER & GIBBS, of Spring Gardens, W.C.

THE BRANCH HOTEL, BRIGHTON.

OUR illustration shows a building recently erected for Messrs. KIDD & HOTBLACK, LTD., in the London Road, Brighton. Occupying a prominent corner in this, the principal approach road to London-by-the-Sea, and near Preston Park, the aim has been to convey some suggestion of both town and country. The materials used are red brickwork with rough-cast and artificial stonework, the cost being under 3,000*l.* The architects are Messrs. CLAYTON & BLACK, of Brighton.

NATIONAL TELEPHONE COMPANY'S BUILDING, VICTORIA ENBANKMENT, E.C.



WE give a view of the National Telephone Company's head offices on the Victoria Embankment, for which Mr. A. N. BROMLEY, F.R.I.B.A., of Nottingham, was the architect.

EASTERN BUILDINGS.*

IN addressing you this evening, I wish first of all to thank you for the compliment paid me in electing me an honorary member of your Society. The objects you have in view are so closely allied to my own mind and work that I had much pleasure in accepting your invitation.

The selection of pictures I am going to show you are not strictly architectural, but they have a more than architectural interest, because they relate to buildings and to incidents of historical interest.

I consider my work to be the putting into pictorial form the current history of the time, whether at home or abroad, and I shall ask you to believe that you are not only seeing the chief features of Constantinople and places around, but the atmosphere of the life and the history of Constantinople. When I was asked to deliver an address here, it so happened that I was in the midst of arranging my pictures which I had brought home from Turkey, and they struck me as being of some interest and appropriate for an address like this. At the moment they are more than ordinarily interesting, because I was there just on the eve of the change in the old Turkish Government. Practically, I saw the expiring efforts of old Turkey to maintain its ground, and the movement for the reformation which has taken place since.

The mosques are the chief architectural features of the East, and they have a special interest, because travelling, as I have done, all over Egypt, and North Africa, and other Eastern countries, one can compare the evolution of the mosque under different circumstances and see, for instance, the Turkish or Moslem influence brought to bear on the mosques in Constantinople in a very remarkable way. The great mosque of S. Sophia was originally a Christian church in remote times, and there you have the evolution of distinct features of Eastern architecture, of wonderful interest to everyone, whether a student of architecture or not. There is the treatment of the domes, they being a great feature in all mosques, and then the minaret, which was Moslem pure and simple and the influence of ancient temple architecture.

These features are very interesting to follow under different conditions. Thus, the building of S. Sophia goes back to about 500 A.D., and was a Christian church throughout the time of the Byzantine Emperors. The addition of the minarets came after the conquest of Constantinople and the occupation by the Turks. There are few buildings in the old world which have cost as much money as S. Sophia, there being good evidence that several millions of pounds have been spent upon it, until it became one of the finest buildings in the world. It is rather different from the ordinary Mahomedan mosque, which is not usually a glorious place within as is S. Sophia. The interior decoration of S. Sophia really owes its origin to Christian influences. There are 107 columns in the building, two storeys of them of superb marble, which are said to be, although it is a subject of controversy, from Ephesus, and form the most beautiful monuments that any church has ever had. You can see costliness in every part of it; a curious feature is the kibleh, which is a sort of recess indicating the direction of Mecca. Every Moslem on entering the church has a piece of carpet which is for his private use whilst at prayer, and occupies a space about 6 or 8 feet long, and as these run in uneven lines over the floor of the mosque they distort and detract from the architectural beauty of the interior. Another interesting feature is the tribune, a sort of room which the Sultan uses when he goes to the mosque upon great occasions. This is a kind of ornamental pulpit of extreme beauty. The splendid decoration and ornament that follows right round the mosque is also noticeable.

The Mosque of Ahmed is equally important from a Turkish point of view, because it was built by Achmet II., one of the great Sultans, and was not only very costly, but a very ambitious building, and even now on state occasions the Sultan attends service there. One point of interest about this building is the number of minarets. San Sophia has four; usually one or two suffices, but Achmet was ambitious to have the finest display of minarets, and therefore erected six. This produced great internal disturbances among the world of Mahomedans, in the sense that Mecca only had six, and this gave great offence to many people connected with the centre of the Mahomedan world at Mecca, which was only appeased by Achmet contributing a seventh to the mosque at Mecca.

The Mosque of Suleiman the Great exhibits the same characteristic features of the building with minarets outside. The open space in front was in ancient times a great cistern for water. Constantinople is very remarkable in regard to its supply of water. It has no natural supply, the water being brought by conduits from a great distance, and at the present time the great reservoir for Constantinople is underground. In olden times there were a number of these underground cisterns; some of them have since gone into decay and disuse, but are still to be seen, and are very beautiful. They appear to be constructed of pillars brought from other buildings or countries, great monoliths of different sizes. The interiors of these cisterns are lighted through shafts, and are now used by silk weavers, and are as beautiful as some ancient church. One of these cisterns, in the centre of Constantinople, is very large and is called the Hall of the Thousand Columns.

Another beautiful building is in the old Seraglio of Constantinople, now used as part of the museum. It is, I think, the most beautiful I have seen in Constantinople.

It is interesting to note that the history of Constantinople is strangely mingled with our own history of the Crusaders and all kinds of familiar events associated with places out there. The siege of Constantinople alone is one of the most marvellous, the most cruel and tragic episodes the world has ever seen, when the Moslems swept like a wave not only over Constantinople, but over the South of Europe. The conquests of the early Moslem Emperors of the thirteenth and fourteenth centuries have been more or less retained, and have had a remarkable effect on the world.

The picture of the Mosque of Mahommed Ali not only shows the extraordinary beauty of its minarets, but gives me an opportunity of saying a word or two about the Moslem religion, because there is no doubt that the discipline and forms of a religious people have a great influence on the world, and I have always thought that the ritual of the Mahomedans, simple in itself, is one of the most powerful weapons that has moved the world, politically or religiously, at any time. First of all, a Moslem to be a good Mahomedan does not require much to impress him. "Allah is good! Allah is great! and Mahomet is his Prophet," is the simple formula that every Moslem needs to repeat several times every day. Minarets therefore play a considerable part in the influence of this worship. They are made with a staircase inside, and the man who calls them to prayer ascends to one of the galleries, and you hear the call at various hours travelling across the houses in a sing-song note, "Come to prayer! Come to prayer! Come to prayer! Prayer is better than sleep! God is the only God!" and so on. This is very effective, and being done at each mosque everybody is reminded by this call of the human voice to come to prayer. This binds the whole of these people together so strongly that the moment there is any prejudice they have only to appeal to the religious bond which binds them all, and the whole of the Mahomedan world becomes fanatical and extreme. It is very wonderful how so small a service, so easily performed, has become so effective a power.

The cloistered forecourt has a fountain in the centre in which the men wash before they say their prayer, so that at every mosque there is provision in this courtyard for washing. There is a beautiful fountain in the forecourt of the great mosque at Constantinople called after Suleiman the Magnificent, who was in power at a period when the Government was most powerful and brilliant; and there are many things of that period, such as works of art, which illustrate to what a pitch of refinement and skill the people had arrived in the sixteenth century; the Korans, the carved kiblehs, and the inlaid work of pearl make that art period one of very great importance, and in themselves form a very good illustration of the riches of that time.

One of the most remarkable ecclesiastical buildings—if one may call them so—is the Mosque of Amru at Cairo, and it is one of the oldest, being first erected in the seventh century.

The influence of the repeated column in giving architectural effect and beauty is very remarkable, and I defy anybody to go through that building without being struck by the singular beauty of the whole. There are columns after columns of these, most of which had been brought from abroad.

Again, the Mosque at Cordoba, in Spain, shows the beauty of repeated columns with Moorish or Arabic ornament. There is the same repetition of pillars at the Mosque of Amru, which survived from still more ancient times, such as the early Temple of Jerusalem; and other very ancient temples, like Mecca, are in the same way simply a repetition of columns, the same as they would get from

* A paper by Sir J. Benjamin Stone, M.P. (Hon. Member), read at the last meeting of the Society of Architects.

Digitized by Google

Egyptian, as exampled in the remains of the clustered columns and spacious courts of the great temples at Luxor, and from Asiatic sources, but in each case the great idea has been to develop the ornamentation, and the manner the pillars are placed gives them a distinctive character in each country.

The Mosque at Mecca.

This picture was obtained under very difficult conditions. The Arab who gave it to me had been appointed sanitary inspector of the pilgrims travelling to Mecca. There is a tremendous difficulty so far as proper sanitary arrangements are concerned. On this occasion and at the risk of his life he took this picture and made me a present of it. But he dare not let anyone know that he had it in his possession, and his only means of conveying it to me was at the moment my train was leaving Cairo, when he put through the window of my compartment a package some 30 inches by 20 inches, with the caution, "Don't look at it till you are out of the country." This picture gives you a real idea of the pilgrims assembling at the great mosque at Mecca. The visit to the "Kaaba" or inner temple covered with the sacred carpet forms another of their great religious expressions. Two or three of these sacred coverings are taken there each year—one from Cairo, one from Constantinople, &c. I was in Cairo when the sacred carpet left for Mecca with the pilgrims. It was a most remarkable sight; the whole of the Mahomedan world seemed to give themselves up to a kind of ecstatic fervour to see this carpet go. They take it to Mecca, and to get there takes quite six weeks. The Khedive and thousands of soldiers see them off at starting. I have a picture of the scene. It is a very important factor in the life of a Mahomedan, because after he has been to Mecca he is permitted to wear a distinct dress, consisting of a green turban, &c., consequently the desire to possess this distinctive dress gives a great impetus to these pilgrimages. A military escort goes right through with them, as it is a very serious undertaking to conduct twenty or thirty thousand pilgrims such a journey, liable to being attacked by warlike tribes. The interest altogether in these pilgrimages has a considerable bearing upon the political history of the country.

The Mosque of Keit Bey, at Cairo, shows the minaret treated with a more ornamental and finer kind of decoration altogether. It is indeed very beautiful, but not only that, the dome is a great feature, its decoration and ornament being of a most elaborate character, purely Arabic; and I think on closer inspection you will agree that the details will bear investigation and are quite characteristic, because they contain words from the Koran, which form part of the ornament.

An interesting mosque at Constantinople is the Mosaic Mosque, which was originally a Byzantine church, the minarets being added afterwards. This is of special interest because it is one of the most famous churches for decoration in mosaic work. The Emperor William of Germany visited Constantinople a year or two ago, and had a desire to see the mosaic work that decorated the inside of this church, but it had all been whitewashed over and not seen for perhaps centuries; however, it was all cleared and the mosaics made visible, but as soon as the Emperor had departed it was all whitewashed over again.

The very famous mosaics of the fifth century at Ravenna, perhaps the best the world can show, are very much of the same character as these.

The interior of the Mosque of Murad II., at Brussa, shows a very simple but interesting form of decoration. Brussa was, before the Turks invaded Europe, the metropolis of the Turkish empire. This mosque has the fountain inside. The ornament, of fifteenth-century work, is very effective.

The walls of Constantinople and other crumbling ruins, once the pride of the Byzantine and Ottoman empires, are most interesting. To look at some of them you would imagine that the great siege could not have been more than a few years ago, although in point of fact it took place in 1452. The prison of Animas, where famous men were imprisoned, possesses a more thrilling interest than perhaps any other building. Great monarchs of Constantinople at different times were imprisoned in this fortress, the dungeons of which are so far down that a lighted newspaper allowed to fall from the top looks like a small star at the bottom.

The Postern Gate is interesting, for it was through here, by a stupid oversight on the part of some soldiers who had left it unfastened, that a rush was made by the advancing Turks in sufficient numbers to prevent it being closed again, and killing the defenders at this spot, took the besieged on the flank at one of the main gates and made way for the whole army to enter. The story of the siege of Constantinople is equal, in romantic episodes, to any historical event in the world.

In olden days, when the Sultans were at the height of their power, they entered the city through the Golden Gate. All people of distinction, conquerors, Roman Emperors, the Roman armies, all entered through this gate, and the story of Constantinople is practically written in it. Around you have the endless cemeteries and monuments marking the events of death through countless ages, and they are still burying and adding to the monuments. The place has a double interest to ourselves, for this was the actual field where the Crusaders pitched their tents when they besieged Constantinople and is still called the Crusaders' field.

The cemetery of Eyoub, where great people of Constantinople, emperors and others have been buried, is a great place of pilgrimage and is one of the most interesting spots, as it overlooks the whole of Constantinople. You see S. Sophia, and further along Sulieman, and so on, and at the top of the Golden Horn war vessels anchored.

What I went to Constantinople especially to see were the famous Sidon tombs. There are seventeen of them in number and were discovered at Sidon, in Syria. They had been the tombs of great potentates of Tyre and Sidon. They may still be considered the most beautiful in the world. They were worked in the age of the Elgin Marbles, and the attitudes of the human figures and the action of the horses are excellent. Their perfect condition is amazing, considering it is about 2,200 years since they were carved. One is called the Tomb of Alexander, because Alexander's figure is on it, but that is only a name for it, as he died and was buried at Alexandria, therefore it could not be his tomb. There is no real record of who were buried in them or who made them; absolutely all trace has been lost. They were hidden in a mountain side of rock and discovered quite by accident. All we know of them is the style and extreme beauty of their ornament. They form some of the greatest treasures of Constantinople; another tomb was brought, not from Sidon, but from North Africa, and illustrates a story from Euripides. Indeed, there was and is now a tradition that it was actually the tomb of Euripides, though there is nothing to confirm it except the story which appears carved on the outside.

To get a more general idea of the country I determined to visit Brussa and Nicea, the latter being the place of the great councils on the ancient creeds.

At Brussa a torrent runs through the town, and the houses on the bridge with the gorge below form a beautiful picture. Brussa is a famous place, for at one time it was the great stronghold of the Turks before invading Europe, and as a place of military operations was famous long before the Crusaders occupied it.

Nicea is nothing but glorious ruins of former greatness, the tombs of some of the great Emperors of Nicea, and the associations of the religious events which occurred there.

If time permitted much more might be said about each of the pictures I have exhibited; indeed, every one might form a text, the story of which could be indefinitely extended.

THE EDINBURGH COLLEGE OF ART.

THE opening of the Edinburgh College of Art, which has been erected on a site at the Cattle Market, Lauriston, has been fixed for January 6. It had been hoped that the College would have been ready for occupation at the beginning of the session in October, but as the building was not finished, the opening ceremony was postponed. The formal opening will be deferred till the whole building is completed, and on account of want of space, invitations for the ceremony on the 6th will be restricted to the Town Council, the College committee, the subscribers, the staff and the students. On the following day the second half of the winter teaching session will commence.

It may shortly be recalled, says the *Scotsman*, that the Edinburgh College of Art has been established by the Town Council at the request of the Scotch Education Department to serve as a central institution for art education in Edinburgh and the south-east of Scotland. It incorporates the work of the Royal Institution School of Art, formerly carried on by the Board of Manufactures, and that of the Art Department of the Heriot-Watt College, and its cur-

Digitized by Google

riculum provides for the study and teaching of the Fine Arts and of the Decorative Arts and Crafts. The administration of the working and affairs of the College are by the articles of constitution committed to a Board of nineteen members of which the Lord Provost is ex officio a member and chairman. Nine other members of the Board are elected by the Town Council from their own members, five by the Royal Scottish Academy, one by the School Board of Edinburgh, and there are three co-opted members. The Town Council gave the site in Lauriston gratis; a grant of 30,000*l.* was received from the Scotch Education Department; 10,000*l.* was got from the funds of the Board of Manufactures, and the public subscribed some 15,000*l.*, which included a handsome donation of 10,000*l.* by Mr. Andrew Grant, Pitcorthie, Fifeshire. These sums were available for the building and furnishing of the College. At present the maintenance of the College is by students' fees, a vote by the Town Council from the residue grant and a grant by the Scotch Education Department. Since October the teaching of the College in its various branches has been carried on under Mr. F. Morley Fletcher, the new director and a staff of competent teachers, at the Mound and in the art class rooms of the Heriot-Watt College. So far the new College arrangements have been a great success. The number of students who have entered is 710, which is about 100 more than attended the Mound and Heriot-Watt classes last year. In the circumstances, however, the work has been conducted under considerable disadvantages. The transfer of the College to the new buildings will, of course, greatly tend to the comfort of the students and of the staff and to the efficiency generally of the teaching; but the full effect anticipated will not be realised until the whole of the College buildings are completed. The need of the building scheme being proceeded with as soon as possible is shown by the fact that until the College buildings are completed it will be necessary to restrict the development of the teaching of crafts, which it is intended should become a feature of the College, and that in the meantime the College will be deprived of part of the library accommodation, the lecture hall, and the staff of their common room. It may further be mentioned that the magnificent collection of statuary belonging to the Board of Trustees, which was formerly exhibited at the statue gallery in the Royal Institution, has been handed over for the use of the new College. There is a condition, however, that it should be exhibited under certain conditions to the public. This cannot be implemented until the College buildings are completed. In the meantime these casts will have to be stored in the vaults of the College. The difficulty in finishing the building at present is, of course, due to the delay which has occurred in connection with the removal of the Cattle Market to Gorgie—a work which, in the interests of all concerned, it is hoped may now be pushed on with all despatch.

The part of the College now completed is, roughly speaking, about three-fifths of the whole building as originally designed, its frontage to the south being 206 feet, and that of the completed building 346 feet. The original plan has been carried out almost exactly as designed, excepting for such minor alterations as have been found necessary in order to permit of the temporary occupation of certain class rooms and other apartments by departments of the College, which will eventually be housed in the remaining section of the building.

The building was originally designed with an entire absence of decorative treatment, but it was afterwards decided to add certain architectural features, which have greatly increased its interest and dignity. The south front, from which the College is entered, has now a projecting colonnade, which will form the centre of the completed building. The colonnade has four Roman Doric columns extending from a raised base to the main cornice. The columns are 3 feet 8 inches in diameter and 31 feet high, and are surmounted by a pediment which at some future time may be completed with appropriate sculpture. The remainder of the façade is plainly treated with broad lines of rustication up to its western extremity, where it terminates with a square projecting pavilion treated with Doric columns similar to those of the colonnade flanking its windows. Owing to the large size and necessary irregularity of the windows which light the sculpture and painting rooms, the treatment of the north façade had to be of a simple kind, and it was only possible to relieve its monotony by slightly emphasising the corners and centre and by raising the roofs over these portions to a higher level than those of the general building. Seen from a distance, the enforcement of the angles of the building, and the greater height of the centre roofs are relied on to indicate the size of the building and to mark its important public nature. The west front is flanked by the corner pavilions, and the one-storeyed building between them is surmounted by a balustrade. The masonry is of red Dumfriesshire stone, and the roofs are covered with green slates.

The entrance doorway, which is in the centre of the colonnade, opens into a hall 32 feet square, flanked by the office on the right and the janitor's room on the left. This hall has four Doric columns, which serve to support the walls of the floor above. Directly facing the entrance is the main staircase leading to the upper floors. On each side of it are the stair to the basement and a corridor leading to the north wing. From the north end of the hall wide corridors branch to right and left, from which the rooms on the south front are entered. The rooms in the south wing are ultimately intended to be used as a lecture room, room for elementary modelling, and a workshop. The lecture room, measuring 28 feet by 26 feet, will for the present be used by the Board and by the director, Mr. Morley Fletcher, and the elementary modelling room, which measures 86 feet by 26 feet, will have to serve partly for elementary modelling and partly for elementary drawing. The rooms on the west wing are laid out as a workshop and pointing and carving room, and at the north extremity is placed the clay room, practically equi-distant from all the class rooms in which clay is used. A separate access is provided from the outside to these rooms, so that stone, marble and heavy materials can be conveniently brought to them. The pointing, carving and plaster-casting rooms are provided with an overhead travelling crane for the convenient handling of heavy materials.

The rooms on the north front are ultimately to be used as modelling life class rooms for men and women, modelling and elementary drawing, but for the present there will be one modelling life class room only. The two life class rooms, which are lighted by windows 18 feet high, are 30 feet square and 30 feet by 35 feet respectively, the professor's room being placed between them. The modelling and elementary drawing rooms measure 54 feet by 30 feet and 66 feet by 33 feet respectively, and are so arranged that they can be divided by curtains, so as to neutralise the effect of cross lighting. The corridors, which are lighted from a centre court, are 9 feet 6 inches wide.

It was recently decided that accommodation must be provided for house painters' instruction, and a portion of the centre court has, therefore, been roofed in, affording a space 56 feet by 39 feet for that purpose.

The main staircase has a central flight to the first landing, from which point it branches to right and left. The steps are of stone, and the upper flights have stone balustrades. On the first floor landing, from which corridors branch to right and left, is the hall in which general meetings will be held, and in which students' work can be exhibited. The hall measures 60 feet by 30 feet, and it is provided with lighting from the roof in addition to that from the windows. This room will be used for the present for architecture until the permanent rooms are built. The room next it is the library, 40 feet by 26 feet, and beyond that are rooms ultimately to be used by the librarian for keeping students' proofs, and for professors and assistants' common rooms. Until the necessary accommodation is provided in the new section these rooms will be utilised for teaching design, and as a lecture room. The rooms to the north ultimately intended for post-graduate students and life and composition are temporarily prepared for painting from the life, there being separate rooms for painting from life for men and women. In the basement there is a large cloakroom, and the rooms ultimately to be used for the crafts will at present be occupied as common rooms for the students and staff, the west room only being devoted to the purpose for which it was constructed—instruction in metal work and glass staining.

All the rooms are finished with the greatest simplicity, the walls being lined to a height of about 11 feet with plain match boarding stained to a dark grey colour, and above that plain plaster. The life class windows are double-glazed, with sashes which open to allow of cleaning both window surfaces, and the electric lighting is arranged so as to give each student lighting at any desired height independent of that arranged for the model. The heating is by hot water on a new system, by which circulation is greatly accelerated, thereby permitting the use of small distributing pipes, and affording effective control, so that the temperature can be

Digitized by Google

quickly increased or reduced. Exhaust electric fans are provided in central positions, to which large shafts are led from the various rooms. The whole of the class room floors are of wood, carried on reinforced concrete for fire-protection, the corridors are laid with plain red square tiles, and the workshops with asphalte on concrete. The architect of the College is Mr. J. M. Dick Peddie, 8 Albyn Place, who, it may be remembered, took up the work on the special invitation of the Town Council, and has carried it through on the lines of a scheme which was drawn up by Mr. Pittendreigh Macgillivray, R.S.A. The result of his professional skill is a building admirably fitted in all respects to the purposes for which it is designed. At present the entrance to the College will be by Lauriston Street.

THE ROSYTH NAVAL BASE.

ON December 22 all offers made by contractors for the enclosed docks and necessary sea walls and quays at Rosyth Naval Base were due to be lodged with the Admiralty. It may be recalled, says the *Scotsman*, that for this important naval work, of which so much has been lately heard, some twenty large contractors in the United Kingdom were invited by the Admiralty to estimate. Five Scottish firms are included in the number, viz.:—John Best & Sons, Ltd., Edinburgh; Morrison & Mason, Glasgow; Charles Brand, Glasgow; James Young & Sons, Ltd., Glasgow; Robert M'Alpine & Sons, Glasgow. It is generally expected that the name of the successful firm will be made known about the middle of January, and that a beginning will be made with the preliminary operations by the end of that month. This will include the erection of suitable accommodation for the large number of navvies and other workmen who will be first brought upon the scene and a pumping station.

Representatives of the various firms competing for the contract have for a considerable time past either been periodically visiting the district immediately surrounding the base or been in residence near it. This was, of course, for the purpose of securing an intimate knowledge of the nature of the work and sources of supplies. It will be readily understood that the range of subjects on which definite and reliable information was required, for the taking out of quantities, the securing of sufficient suitable material at the nearest possible sources of supply and up to the standard of samples supplied by officials of the Admiralty, the reckoning of the cost of carriage, the consideration of the most efficient means to be adopted for the removal of the enormous quantities of sand, gravel and stones required for the formation of the enclosing breakwaters and piers, and for the removal of rocks, clay and silt lying within the area of the basin to be excavated and dredged, was of necessity a very wide and comprehensive one.

Quite naturally the greatest reticence has been maintained by representatives of competing firms as to their proposals for carrying out the work and as to facts and figures which, if they leaked out, might be used to advantage by rival firms. At the same time, the quantities of raw material which will be incorporated in the concrete work are fairly well known. The nature of the strata to be met with in excavating for foundations and in the deepening of the enclosed area of the base, the possibility or otherwise of utilising the material so removed for the foundations or concrete superstructures, and the necessity for removing to a distance silt, are all factors of the greatest importance in the calculations of the engineers. Reliable information as to these is a sine qua non, and involves trouble and expense in the making up of estimated costs.

A certain kind of accommodation for a limited number of navvies is already provided in the district, but while this may be said to be of the usual kind provided for similar works, it has been indicated that it is hardly of the nature which will satisfy some of the competing firms. The navvy, of course, will be at liberty to choose his abode, but it is under contemplation to provide such accommodation as would offer perhaps more comfort and at least greater privacy than can be commanded in the huts usually run by private enterprise. One of the first constructive works to be undertaken will therefore in all likelihood be the erection of suitable houses or superior kind of huts to provide accommodation for a good 2,000 navvies. These will be placed on ground lying between the naval base works and the burgh of Inverkeithing. Something, however, may be done to provide means of communication between the base works and large centres of population within reasonable distance and where accommodation may be available, such as Dunfermline and Edinburgh and Leith. From a consideration of the comparatively few miles intervening between Rosyth and Dunfermline, it does not appear that much difficulty would be experienced in providing ready access, as they are already connected by very direct roads and might easily be converted or adapted for tram or electric traction. On the other hand, as was done during the years when the Forth Bridge was under construction, it seems quite feasible for the North British Railway Company to arrange a special train service between Rosyth and the capital. Undoubtedly, as on the occasion referred to, many of the better class of tradesmen, engineers, mechanical and civil, and heads of departments, would prefer to reside in Edinburgh. As before, it might also be expected that many of the younger class of employés in various departments would eagerly seize the opportunity which would thus be presented of attending the technical and art classes in the city. Then there comes in the question as to how the facilities thus secured would affect the interests of sub-contractors and their employés. There is every indication of the fact that the former will be largely employed, as usual on such work, but many of these questions will undoubtedly depend for solution on the selection of the successful chief firm of contractors.

The term for the completion of the section of the great work at present contemplated is about seven years, but it is suggested that there is a possibility of a more extensive scheme being thereafter entered upon, if it be not actually put under way at an earlier date, when docks of various kinds would have to be constructed. There is thus some justification for expecting that the work soon to be begun at Rosyth may easily be extended to a period of something approaching twenty years. Owing to the fact that a large bonus is offered for the construction of the works at an earlier date than is specified in the contract, it is certain that the present undertaking will be pushed on with all diligence by the contractors. The firm successful in securing the contract will be called upon to give a security of probably a quarter of a million pounds.

The nature of the material to be excavated has been carefully ascertained as far as possible by an extensive series of borings, the material brought up having been carefully noted and to a large extent preserved for reference. In various other ways, sometimes by the competing firms independently of what has been ascertained by the firm which has been engaged in the sinking of a trial caisson on the spot, and by various recognised methods among experienced engineers, the nature of the bottom and thickness of the underlying strata have been mapped. The measurements, the quantities of material to be excavated from within the enclosed basin by pumping, dredging and blasting, the cost of removal of such material as will not be available for the structure, and of the heavy blasting operations necessary for the removal of the basaltic rocks of Dhu Craig have all been reckoned with in the making up of estimates. Where such huge quantities of material have to be dealt with it is only natural that some discrepancies should be apparent in the relative estimated quantities of the various items making the common grand total. From what can be learned, however, it may not be very far off the mark to say that something over one million tons of sand, which must be equal to samples submitted, and a quarter of a million tons of gravel or crushed stones suitable for the specified concrete work, will be required. To represent these quantities in another though rough and ready fashion, it may be said that the amount required would represent something like a twenty-acre field 30 feet deep all over. Part of this quantity will require to be sharp pit or fresh water sand, and the remaining portion will consist of washed sea sand. The sea sand will be used for the construction of the submerged parts of the walls, and will, according to modern practice, be probably secured by pumping from below high-water mark from the large sand-banks which line both shores in the lower reaches of the Forth. This may be transported by rail or conveyed, which is more probable, directly from the banks to the base by means of barges. The means adopted will depend on the very important consideration of cost of carriage. The Board of Trade has already sanctioned the removal of between three and four hundred thousand tons of sea sand from a part of the foreshore in the vicinity of the base during the next seven years. An enterprising firm has already also secured the rights to most of the extensive sand beds in the Forth, as well as inland in the neighbourhood.

The contracts going in for the consideration of the Admiralty will work out at something between two and three millions sterling.

HOUSING IN LONDON.

THE housing of the working classes committee have informed the London County Council that they have had under consideration a comprehensive report on the present aspects of the housing question in London. The report, which has been prepared by the statistical officer, deals in the first place with the conditions now prevailing in London and in "Greater London," or the area which comprises the metropolitan and city police districts. The population of the county has steadily increased during the last century from 959,310 in 1801 to 4,536,541 in 1901, and though the rate of increase is now declining, the increase in numbers is still considerable. Since 1861 the population of the extra-London districts has grown rapidly, the increase for the decennium 1891-1901 amounting to no less than 639,372, whereas the increase for the same period in the county of London was only 308,224. In eleven metropolitan boroughs and in the city of London the population is either diminishing or stationary. An interesting comparison is drawn between the cost of accommodation in the central area and in the suburban districts, the latter including the cost of workmen's fares by train or tram. The comparison is mostly in favour of the suburban districts, and it is demonstrated that it is now quite possible for a working man to obtain dwelling accommodation in the suburbs and to pay the cost of travelling to and from his work without incurring any additional expense over the cost of accommodation in the central area. On the subject of overcrowding attention is directed to the fact that in 1901 there were in the county of London 2,449,789 persons living in tenements of one to four rooms, of whom 726,096, or 29.6 per cent., were living under conditions of overcrowding, as judged by the standard of two persons per room. The figures for that year show that the greatest degree of overcrowding existed in the metropolitan boroughs of Stepney, Finsbury, Holborn, Shoreditch, Bethnal Green, St. Marylebone and St. Pancras. A striking feature, which renders a solution of the housing problem more difficult, is the absence of any relation between the number of empty houses and the amount of overcrowding in a particular district. For example, in Stepney, where it appears from the census of 1901 that nearly 100,000 persons were then living under conditions of overcrowding, recent inquiries in various parts of the borough indicate that there is no lack of vacant working-class accommodation. There is little doubt, however, that taking London as a whole, by far the greater proportion of empties occurs in better-class property.

The report next deals with the changes in working-class conditions during recent years. Wages have increased, while the price of food and other necessaries has fallen. On the other hand house rents have risen, but on the whole it may be taken that the position of the labourer from a financial point of view has improved. Another important factor in the housing problem is the prospects of the future demand for labour in London. In the last few years a number of factories have been removed from within the county, but, from an examination of the available statistics bearing upon the subject, there seems to be no reason to anticipate that, apart from local fluctuations, the demand for labour in London will show any departure from the steady growth of past years.

The report further touches upon the methods of dealing with the housing problem. In the first place it is pointed out that the erection of working-class dwellings is a type of enterprise which does not call for the creation of a monopoly in order that it may be economically administered. At the same time the competition of the Council in the past has not been without its good effects in maintaining and improving the standards of construction and accommodation and particularly the standard of sanitary requirements. During the past six years only 7 per cent. of the new accommodation in London and the suburbs was provided by public bodies, and there appears to be little doubt that whatever the policy of the Council may be, the bulk of the accommodation will continue to be provided by private enterprise. It is found, however, that while working-class families requiring four, five and six rooms are being amply provided for in the suburbs, there is not much provision made for families who can only afford to pay for two or three rooms. The committee regard this fact as tending to justify the policy they have suggested to the Council of confining its operations as far as possible to the provision of accommodation at rents ranging from 7*s.* to 10*s.* a week. On the question of where accommodation is most needed, the report states that it is usually desirable, if sufficient opportunities of cheap transit exist, to ease the pressure of competition for house room by building further out, where land is cheap, rather than add to the accommodation in the particular locality, especially as this latter course usually involves a loss. Also it may safely be accepted that building should not be undertaken in suburban districts which already contain a proportion of working-class population largely in excess of the normal. In the county of London the pressure on working-class accommodation is probably greatest in the district north of the Thames and west of St. Pancras, but it does not follow that the need for accommodation can be met to the best advantage by building dwellings in that particular district. It may be that the provision of cottages further out, with the necessary travelling facilities, would be more beneficial to the population concerned. Bearing in mind these various considerations, the Council's estate north of the Thames, at Old Oak Common Lane, Hammersmith, appears to be favourably situated for the purpose of meeting the special difficulties existing at the present time; but the White Hart Lane estate, being in a district where the working-class population already predominates largely, is not so satisfactory. The further provision of working-class accommodation, whether by private or municipal enterprise, might be most advantageous to the proper spreading of the community if undertaken in districts beyond the county in the north and west. South of the Thames the Totterdown Fields and Norbury estates are both well situated for meeting the need for expansion, and the development by private enterprise of land at Wandsworth, Lewisham and Eltham, already progressing so far as four, five and six-roomed cottages are concerned, is calculated to have similar desirable results if smaller cottages are provided and the means of transit cheapened. The importance of locomotion facilities as a factor in the solution of the housing problem cannot be too greatly emphasised. Since the passing of the Cheap Trains Act in 1883 the number of workmen's trains run has increased enormously, and this, combined with the growth of the electric tramway services, has greatly encouraged the very wholesome movement of the working-class population from the overcrowded central districts. With the growth of population the cheapening of the workmen's fares on railways is likely to become a more pressing question in the future. What is required to cope with the problem of properly distributing the population is not exceptionally cheap fares in one direction, but fares such as workmen may reasonably be expected to pay in all directions; and it is a matter for consideration whether railway companies should not be required to run workmen's trains to serve districts which are in process of development, without waiting until a large working-class population is actually in residence. The question of the convenience and sufficiency of the service of workmen's trains and trams will also become more important. The committee endorse the views expressed in the report, which they commend to the earnest consideration of the Council. They have given instructions for a copy to be sent to each member of the Council, and recommend:—"That the report of the statistical officer presented by the housing of the working classes committee, on the present aspects of the housing question in London, be placed on sale at the price of 4*d.* a copy."

INSTITUTION OF CIVIL ENGINEERS.

AT the ordinary meeting on Tuesday, December 22, Mr. James C. Inglis, president, in the chair, the paper read was "An Investigation of the Heat Losses in an Electric Power Station," by F. H. Corson, A.M.I.C.E. The following is an abstract of the paper:—

An inquiry, originating from Blackburn, in 1903, showed that the average coal consumption of thirty-four principal generating stations of the United Kingdom was about 7.7 lbs. per unit generated. The figures ranged from 3.6 lbs. to 15 lbs., Blackburn standing at 10 lbs.

Rough tests on the various sections of the plant resulted in considerable re-arrangement. The steam-pipe system was overhauled and more effectively drained, and steam separators and driers were in consequence dispensed with. Engine stop valves were, where possible, attached directly to the main steam pipes. The steam ring was discarded, and generally the effective heat-radiating surface was greatly diminished. Better fitting boiler dampers were provided, the condition of the brickwork was improved, and the whole process of combustion was more thoroughly controlled by the institution of flue-gas analysis. These and similar alterations occupied three years, and the fuel consumption fell during that time to about 6 lbs. of the same coal per average

Digitized by Google

unit generated, a reduction of 40 per cent. Further progress being imperative, it was decided to conduct tests covering the whole operation of the works, viewing the losses peculiar to each part of the plant in their relationship to each other and to the whole; and arrangements were made, and apparatus devised, for their prosecution. After isolated trials of the various types of apparatus had proved their reliability, simultaneous tests were arranged, of a duration long enough to embrace all conditions of operation met with in routine work.

The Blackburn undertaking comprises two adjoining stations of 2,300 kilowatts capacity each, containing twelve mechanically fired Lancashire boilers, six fitted with superheaters; fifteen high-speed engines driving generators from 60 kilowatts to 775 kilowatts in size, controlled from three switchboards; steam piping 3 inches to 14 inches in diameter; ejector and jet-condensers fed from an overhead water-tank above the boiler-house; low-speed steam-driven feed-pumps; four batteries of economisers totalling 1,504 tubes; two chimneys, 150 and 250 feet high respectively. The test has covered during 168 consecutive hours the combustion of about 230 tons of coal, the evaporation of 3.376 million lbs. of water, and the generation of 99.295 electrical units. The net results show a consumption of 5.15 lbs. of coal, and a total evaporation of 33.9 lbs. of water per average unit.

Observations have been taken half-hourly of the rate of evaporation, and of the temperature of the feed-water at the feed-tank, and the economiser inlets and outlets; of the chemical composition and temperature of the gases in boiler and economiser flues; of the temperature and pressure of steam supplied to and discharged from the engines; of the temperature and quantity of the injection and discharge water of the condensers; and of the electrical units generated.

Some of these data have also been obtained by using recording apparatus. The performance is shown on a time basis in curves, and in total in eight balance sheets relating to the operation of the whole plant and of its constituent parts. So far as possible, the results have also been entered on the form prescribed by the Institution committee on steam engine and boiler trials.

The principal sub-divisions into which the trials have fallen are:—(i) fuel selection; (ii) estimation of moisture in coal; (iii) determination of calorific value; (iv) flue-gas analysis and measurement; (v) evaporation of water and distribution of steam; (vi) steam consumption of auxiliaries; (vii) steam consumption of main engines; (viii) measurement of output.

1. *Fuel Selection.*—This has been effected after comprehensive trials, involving calorimetric determination and actual working test of various fuels. The insufficiency of the calorimeter indication alone is shown in Table I., and it has accordingly been used only as a preliminary guide, supplemented by practical trial under working conditions. As a means also of ensuring uniformity of supply of fuel, the employment of the calorimeter has been largely discarded, more reliance being placed on observation of the coal in actual use. To exhibit the results quantitatively, the calorimetric determination of the heat value of the coal has been adopted.

2. *Estimation of Moisture in Coal.*—Every load of coal entering the works is sampled at the weigh-bridge. All samples, roughly 1 lb. in weight each, are mixed at the end of the day, and dried, the loss of weight being approximately a true statement of the moisture contained. Periodical tests have been applied to check the accuracy of the method, and have shown that some water, about 1 per cent. of the weight of the sample, still remains. With this correction, the moisture is estimable by these means with close approximation, and uncertainty as to the efficacy of the process is overshadowed by the greater doubt accompanying any calculation of the qualities of the whole from those of a small part. Tables show the results of the moisture tests for nine months.

3. *Determination of Calorific Value.*—The Thompson calorimeter has been modified for the removal of certain liabilities to inaccuracy existent in its original form. Oxygen supply from a gas cylinder has replaced that from potassium chlorate and nitrate, rendering combustion more controllable, and securing better transference of heat to the water. Electric ignition has ensured thoroughness of combustion, and external silvering of the outer vessel has reduced radiation error. Curves illustrating the diminution of radiation resulting from the external silvering are given. The mean calorific value from seventy-three tests of the dried fuel is 13,180 B.Th.U. per lb., or, allowing for moisture, 12,310 B.Th.U. per lb., of the coal as fired.

4. *Flue-Gases Analysis and Measurement.*—The chemical constitution of the flue-gases has been estimated by a Krell CO_2 recorder, and by the Orsat apparatus. Considerable difficulty has been encountered in the selection of truly average sample gas, and a large number of tests have been made to ensure certainty of its representative character at all times. Numerous test-holes have been drilled in the flues, and samples from one point compared with those derived simultaneously from another. Other difficulties have arisen from the type of analyser. After trial of varied arrangements, all such troubles appear to have been surmounted, and the correctness of results has been proved by confirmation of the Orsat apparatus. Diagrams are given of the arrangements made for the purpose of flue-gas analysis, and also typical CO_2 charts obtained from the flues.

Specific Heat.—Some doubt is suggested of the validity of computing the specific heat of the gases from that of their several constituents, and also of assuming the quantity to be independent of change in temperature and pressure. In the inquiry this course has been followed, any error resulting therefrom being probably exceeded by possible uncertainty of the chemical analysis.

Temperature.—Four certified mercury pyrometers, one of recording type, have been used for this section of observations. Temperature records from boiler and economiser flues are given.

5. *Evaporation of Water and Distribution of Steam.*—The feed-water has been registered by a Siemens water-meter in the pump suction-pipe, the instrument being tested daily on the pumping, at various rates, of a measured quantity of about 2,000 gallons. Errors of the meter, due to the presence of air-vessels, were encountered, but were obviated, and the half-hourly record of the meter, corrected by the error curves, may be accepted with confidence. The water lost by leakage and by blowing down of boilers has been determinable by direct test, and the radiation loss by shutting off all engine valves and applying still tests of ten hours' duration for the measurement of condensation. This may be inaccurate, for in practice the steam is superheated, but it has been preferred to results obtained from attempts to derive the figure from the fall in temperature accompanying the flow of a known weight of superheated steam.

6. *Steam Consumption of Auxiliaries.*—The tests under this head cover the steam used by furnace grate-jets, by feed-pumps, and by apparatus of domestic character. The first of these has been arrived at by feeding all jets from one boiler, and noting the rate of evaporation; the second, by condensation of the exhaust into a known weight of water at various speeds of pumping; and the third by frequent direct tests.

7. *Steam Consumption of Main Engines.*—The steam consumed by the main engines is deduced from the increase in temperature of the condensing water, the quantity of which has been measured. The accuracy of this method rests upon dryness of the exhaust steam, which appears to be indicated by thermometers and mercury gauges fitted to the engine exhausts.

8. *Estimation of Electrical Output.*—All energy used for whatever purpose has passed through meters calibrated to 2 per cent. accuracy. In conclusion, the author discusses the part played by each possible source of loss in the indifferent thermodynamic performance of the works as a whole. While regretting that circumstances have compelled somewhat superficial treatment of some details, he has confidence in the accuracy of the data obtained, within the limitations prescribed by the apparatus available and by the character and conditions of the trial.

ATMOSPHERIC POLLUTION.

A REPORT for the year of the chemical department of Glasgow Town Council has been prepared by Mr. F. W. Harris, corporation chemist and analyst. In the course of it he says that during the year some of the problems connected with aerial sanitation have been investigated, notably the relative efficiency of coal and gas fires. The results are intended to demonstrate scientifically that the general adoption of gas as a fuel would greatly reduce atmospheric pollution. It is doubtful whether the citizens generally realise all that is implied by the term "aerial sanitation." The ordinary individual probably only realises the extent of the contamination of the atmosphere when, owing to sudden changes in temperature, the city is enveloped in fog;

Digitized by Google

then the impurities are by condensation of the aqueous vapour rendered visible. But is it generally realised that the atmosphere on a clear day is equally contaminated with impurities? At present we are solely dependent upon climatic conditions whether through fog prevailing the city is enveloped in a black pall loaded with impurities, or whether these are driven to the out-lying districts by favourable winds and warmth. The aims of aerial sanitation are not only to prevent the formation of black fog such as Glasgow is occasionally enshrouded in, but to effect a permanent improvement of the atmosphere. It has been suggested that the dispersion of fog can be attained by high-tension electrical discharges. This method, however, has not developed beyond the laboratory stage, probably on account of the large expenditure necessary to experiment on a practical scale. Considered in the most favourable light, such methods are really only palliative measures, and the only practical and economical means by which our atmosphere can be permanently purified is to eradicate the evil at its source. The eradication of this evil can be attained only by educational and compulsory means. Why are our rivers being gradually purged from the foul contamination of domestic sewage and works' refuse? Simply because local opinion has been stimulated to the realisation of the danger incurred. Educate the citizens by means of lectures and demonstrations to realise that the present method of heating and warming domestic dwellings is wasteful, fully 75 per cent. of the available heat being lost. Make each individual realise that pure air is as essential to health as pure water and pure food, and that by the discharge of smoke he is directly contributing to atmospheric pollution, thereby, from a health point of view, injuring not only himself but his fellow-citizens—in other words, creating a public nuisance. Domestic grates require supervision. The Corporation have already control of drains, gas and electrical fittings, likewise possess similar powers over any discharge into the river. Why not extend such powers to the supervision of fire grates and the control of all emissions into the atmosphere? These are all means to attain the end, namely, the abolition of domestic smoke, the evil of which is far greater than is generally accepted. With the manufacturing offender the solution is simply a question of compulsion. Numerous effective methods of smoke prevention are at hand; it only needs effective compulsory powers to remove the source of pollution.

LONDON BUILDING ACTS.

THE Building Act committee of the London County Council in their annual report state that they held forty meetings; in addition there were thirty-six meetings of sub-committees during the year.

The committee administer the London Building Acts, 1894 and 1898 (decisions with regard to the more important provision being subject to confirmation by the Council), the Factory and Workshop Acts 1901 and 1907, in so far as they relate to the provision of means of escape in case of fire, and the London Building Acts (Amendment) Act, 1905, which deals with the question of the provision of means of escape in case of fire in certain classes of buildings other than factories and workshops in which more than forty persons are employed. The Council has also charged the committee with the preparation of the draft by-laws under section 2 (1) of the Advertisements Regulation Act, 1907.

For the purposes of the administration of the Building Acts, London is divided into fifty-six districts, for each of which a district surveyor is appointed. The power of appointment and dismissal of district surveyors is vested in the Council. During the year 9,820 cases under the Building Acts were dealt with, about half the number relating to dangerous and neglected structures, and 6,922 new buildings were examined by the district surveyors, who received fees amounting to nearly 18,000*l.* in respect thereof. 20,172 old buildings were examined, the fees paid to district surveyors on these amounting to over 26,000*l.* It was necessary to take legal proceedings in a large number of cases, either to obtain authoritative decisions or to enforce compliance with the law. About four miles of new streets were sanctioned during the year. In order to obtain the views of all parties interested in the more important applications under the Building Acts, each local authority concerned is asked to express its views before these applications are considered.

Under the Factory and Workshop Act 1,323 cases have been considered by the committee; in 377 of these cases the provisions of section 14 of the Act did not apply and they were, therefore, removed from the list of cases to be dealt with; sixty-five certificates were issued in respect of new factories and the necessary work was completed in 167 old factories. In carrying out this branch of the committee's work every endeavour is made to avoid unnecessary interference with the trade or manufacture carried on at the premises dealt with.

The London Building Acts (Amendment) Act, 1905, is somewhat drastic and is largely retrospective, but, speaking generally, considerable discretion is allowed to the Council in dealing with buildings coming within the scope of the Act, and there is a right of appeal in the more important cases to the Tribunal provided by the Act of 1894. Every effort, too, is made by the committee to administer the Act in a reasonable manner so as to secure the advantages of compliance with the provisions of the Act with as little hardship as possible to the individual. The work involved in the administration of the Act is very heavy, as will be seen by the fact that during the year under notice no fewer than 10,541 notifications were received from the district surveyors under sections 10 and 12 (projecting shops and access to roofs); of these cases 1,482 have been dealt with. The total number of cases reported under these two sections alone was, on March 31, 30,804. The number of applications under section 7, relating to new high buildings and buildings which may be occupied by more than twenty persons, was 412, of which twenty-seven were refused, and certificates were issued on the completion of the works in 161 cases. Notifications were received in respect of buildings in which inflammable liquid was stored in 369 further cases, and 416 cases were dealt with. 238 applications under section 9 of the Act, which relates to existing high buildings and buildings occupied by more than twenty persons, were dealt with.

The question of the further amendment of the London Building Act, 1894, has been under consideration, and on the committee's recommendation the Council decided to insert in its General Powers Bill of 1908 clauses to amend sections 75, 76 and 77 of the Act of 1894, so as to enable the Council to permit the erection of buildings having a larger cubical extent than was contemplated in that Act.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

The Skyscraper Era.

SIR,—In an article appearing in the current issue of *The Architect*, a remark is made "How many there are whose positivism is only equalled by their ignorance." I think Mr. F. W. Fitzpatrick, of Washington, must take rank amongst the above, when he asserts that we English are going to become the slaves to skyscrapers. Is he unaware that our more recent legislation has been directed towards limiting the heights of our buildings; and is he also unaware that even his beloved Americans are showing signs of weariness and dissatisfaction respecting their Jack-and-the-Beanstalk nightmares, and there is somewhat belated talk of promoting legislation for limiting the height of future erections? It may be true that "business men, not artists, constitute the controlling force in politics and municipal affairs," but the views of artists are becoming increasingly respected over here, and the sign is a very healthy one.

We, I hope, are not afraid of taking valuable lessons from our younger brother, but he must not become cheeky all the same, and imagine that whatever he says is valuable.—Faithfully yours, PERCY L. MARKS.

Albert Buildings, 49 Queen Victoria Street, London:
December 28, 1908.

SIR,—The article in your always interesting journal by Mr. F. W. Fitzpatrick I read on Christmas Day, and I found it very entertaining, but does Mr. Fitzpatrick really think that the day of the skyscraper is at hand, in connection with this country? I say in all reverence, God forbid. In America, the home of this monstrosity, the day is "well spent." Rumours are in the air that Congress is to be asked to place an embargo on it. One of the main reasons, I believe, to be advanced is on sanitary and fire prevention grounds, as it is found impossible to obtain sufficient pressure of water to enable it to be procured on the upper part

Digitized by Google

of these outrageous erections. Fancy London or Paris with such buildings. I must not pursue the subject further. I want to finish that interesting paper on "London Taverns in History." Continued success to the dear old *Architect* in 1909.—Yours gratefully, AN ENGLISHMAN.

Architectural and Topographical Society.

SIR,—The recent appointment of a Royal Commission to inquire into the condition and preservation of the ancient monuments of this country is an encouraging sign of an awakened public interest in the magnificent national relics which are thickly scattered about the country.

May I once again claim the courtesy of your columns to call attention to the work of description and recording which this Society has undertaken?

In addition to the minute descriptions of old buildings which we publish (with illustrations) in our quarterly "Record," and the large scale drawings and photographs which we are endeavouring to collect, we have recently decided to issue printed forms for brief notes on buildings which, when filled up, we propose to file in a manner convenient for reference; copies of this form which have just been issued to our members, can be obtained gratis on application at the offices of the Society; and when a number of them have been collected they will make a detailed catalogue of ancient buildings such as, we believe, has not hitherto existed in these islands.

May I appeal to all who have any reliable information concerning any ancient building or buildings to apply for copies, especially to clergymen and others who hold a fiduciary position in connection with such monuments?

May I, at the same time, appeal for the further assistance in the other work of description and investigation which is being done slowly but, we believe, thoroughly; and may I finally call attention to the fact that by increasing the number of our members the progress of this work will be hastened, as the rate of publication is mainly governed by the funds at our disposal?—Yours faithfully,

WILFRID TRAVERS, Hon. Sec.

33 Old Queen Street, Westminster, S.W.:
December 19, 1908.

The appended form is a specimen of those intended for filing amongst the records of the Society, in order that a large amount of information may be accumulated and placed at the disposal of members and others in addition to, and at an earlier date than, the necessarily slow publication of the "Record" will permit. In supplying the details correspondents are requested to take every care to ensure the greatest accuracy, and to include the salient facts rather than unimportant details. It will be noted that all the architectural types are given according to the dates of their erection. Any further details, which will be gratefully received, should be submitted on a separate sheet (or sheets) of paper. Any number of these forms will be issued on application to the Hon. Secretary of the Architectural and Topographical Society.

SPECIMEN FORM.

O.S. No. 269 (1 in.-1 mile).

County of Buckinghamshire. Lat. 51°30′ N.

Parish of Dorney. Long. 0°40′ W.

Name and Use of Building—Parish Church of St. James.

Historical Notes.

Date of Foundation, probably pre-Conquest, is unknown. Tithes and living granted to Burnham Abbey on its foundation c. 1265. A chantry founded by John Scott, temp. Henry VI. A chapel built by Garrard family in sixteenth century.

Features of Building:—Plan.

Chancel and unaisled nave with west tower. Chapel north of chancel. South porch.

Structure.

Chancel contains early work in south wall, much altered in thirteenth century (door and window, now blocked) and fourteenth (low side window on both sides, and chancel arch) east window modern. Nave shows late twelfth century door (blocked) and two thirteenth century doors. Windows—seventeenth or eighteenth century; large, plain, rectangular. Tower—brick with stone dressings, embattled, with hexagonal stair turrets. Two-light belfry windows. West door and three-light windows over; all fifteenth or sixteenth century. North chapel entirely brick, including mullioned square-headed windows; sixteenth century. Porch of brick, partly stuccoed; 1661.

Fittings.

Altar, seventeenth or eighteenth century. Fragments of fifteenth century screen now along east wall. Tub-shaped font, twelfth century, with strap and fleur-de-lys ornament. Gallery dated 1634. Seven old pews, plain, probably of same date. Box pew, with front and outer side cut down, on north side. Two elaborate lead memorial tablets hung on remaining side. In chapel, a large monument to Sir Wm. Garrard (1607) with kneeling effigies. Their children below. Registers from 1538. Plate—Elizabethan.

Armory.

Hatchment over gallery. Sir C. Palmer, or. two bars gu., each charged with three trefoils arg., in chief a greyhound courant sa. impaling az., a lion ramp., reg. arg., crowned ducally or. on tomb. Garrard. Arg. on a fesse sa., a lion pass., of the first. Kedermister. Az., two chevrons or. between three bezants. Nethermille. Arg., a chevron between three crescents az. Rowe. Arg. on a chevron az. between three trefoils slept per pale gu., and vert as many bezants.

Books of Reference.

"History and Antiquities of the County of Buckingham," G. Lipscombe, M.D., 1847; Crown Folio, J. & W. Robins, London.

"The Ecclesiastical and Architectural Topography of England," Vol. II. Pub. under the sanction of the Central Committee of the Archæological Inst., London.

"Victoria History of the County of Buckingham." Constable & Co., 1907, Large Imp. 8vo.

Other Buildings of Architectural Interest in this Parish are:—

Dorney Court.

GENERAL.

Sir Thomas Drew on Saturday gave his annual historical and descriptive lecture on Christ Church Cathedral, Dublin, in the nave of that building. Allusion was made to the satisfactory installation of electric light.

The Sheffield City Council is to be advised to erect a sanatorium for consumptives near Tuxford, in North Nottinghamshire. The grounds which are recommended for purchase are about 34 acres in extent.

The Directors of the City and County of Perth Royal Infirmary have unanimously resolved to proceed with the erection of a new infirmary, to consist of 100 beds, at an estimated cost of 40*0l.* per bed, at Tullylumb.

An Exhibition of French Art is to be very shortly opened in Montreal under the patronage of Lord Strathcona and the French Consul-General. Among the artists represented will be Rodin, Bartholomé, Camille Lefèvre, Abel Marque, Fix-Masseau, Bernard, Voulot.

M. Charles Albert Waltner has been elected a titular member of the Académie des Beaux-Arts, Paris, in the engraving section. M. Waltner is vice-president of the National Society of Fine Arts.

Messrs. Butterworth & Duncan, of Rochdale, have been awarded first prize in a competition for a school at Disley for 350 children, which will cost over 5,000*l.*

M. Pons, pupil of M. Renon, has been awarded the prize and first medal in the Concours Godebœuf (architecture) at the Ecole Nationale des Beaux-Arts. Three pupils of M. Laloux were awarded the three first-class medals.

The Committee appointed to consider the erection of a memorial of the late Canon Fleming in York Minster have decided that it shall take the form of a statue in stone of King Edwin, one of the martyred Saxon kings, to be placed in the beautiful niche on the left or north side of the altar in the choir, at a spot where Canon Fleming frequently stood. King Edwin was baptized very near the actual place, and his head is buried in the Minster.

Mr. E. A. Gruning, of 25 Gresham House, Old Broad Street, and 3 Holland Park, W., died on Tuesday after a short illness. Mr. Gruning practised as an architect and surveyor in the City for over forty years. He designed many buildings of importance, chiefly for bankers, insurance companies, and large mercantile firms. Mr. Gruning, the son of Mr. John Frederick Gruning, was born on June 26, 1837, and married, in 1874, Miss A. A. Cappel. He leaves two daughters and a son. Mr. Gruning was a Fellow and past vice-president of the R.I.B.A., a Fellow of the Surveyors' Institution, and a member of the Tribunal of Appeal under the London Building Acts. He was also a lieutenant of the City.

The Jury in the recent competition for a naval ordnance college to be erected on the Champ-de-Mars have unanimously awarded M. Patouillart-Demoriane the premier place among the twenty-four competing architects. The design of MM. Duval & Gonse secures the second prize, and M. Chaussemiche is placed third. MM. Briasson, Duquesne, Guidetti & Grisolia, Leprince-Ringuet, Sortais, receive awards of honourable mention. The building is to contain sections for a naval gunnery, artificers' school, marine engineering, laboratories, treasury and pensioners' bureau.

MINERVA VISITING THE MUSES.—Frieze by J. B. CIPRIANI, R.A.

THE WEEK.

THE event of the week in architectural circles has been the announcement made by Mr. E. T. HALL, Vice-president and Chairman at the business meeting of the members of the Royal Institute on Monday last, that H.M. the KING had been pleased to grant the petition of the Royal Institute of British Architects for a Supplementary Charter. As the letter conveying this information to the Council was dated on December 31 last, this announcement came as a surprise and a pleasant New Year's gift to the members.

THE chief business before the meeting, according to the notices issued to members, was the consideration of two resolutions to be proposed by private members, each of which was, in effect, a vote of censure on the Council. The first of these, standing in the name of Mr. G. E. NIELD, was as follows:—"The Fellows and Associates of the Royal Institute of British Architects demand, as due to them, a full and satisfactory explanation from the Council, or its responsible officers, of the circumstances leading up to the proposed suspension of part of By-law 9, and direct that in future no such motion shall be moved. They condemn such proceedings as that attempted, and consider it unworthy of the governing body of the Royal Institute." As the object of the Council in abrogating By-law 9, and the objection of many members to their doing so, were alike rendered futile by the announcement of the grant of the new Charter, Mr. NIELD wisely refrained from pressing the merely recriminatory part of his resolution, and withdrew it.

THE second resolution was that of Mr. K. GAMMELL, who moved:—"That the Council of the Royal British Architects shall forthwith give effect to the will of its members, as expressed by the resolution passed in open meeting on January 7, 1907, whereby this Institute showed its disapproval of the principle of limited competitions for public buildings erected with public moneys, by forwarding a copy thereof to the Council of every county, county borough, and borough in England and Wales, before April 10, 1909."

IT transpired that the Council had shelved the resolution of a year ago, and had taken no steps to give effect to it, and it was clearly recognised that Mr. GAMMELL'S motion was a vote of censure on the Council. It was pleaded on behalf of the Council that they considered it unwise to give effect to the resolution of January 1907, and the Chairman, as the spokesman of the Council, practically told the meeting that the Council knew better than the general body of members what was expedient, and that, as their trustees, the Council were not going to let the Institute do a foolish thing. This is surely an illogical and unconstitutional position for any governing body of a society to assume, and is a most unfortunate attitude for the Council to maintain. It was a very general opinion in the room, even amongst those who had come to the meeting with the intention of saving the Council from the ignominy of a vote of censure, that the Council had not acted wisely, either in the matter to which Mr. NIELD'S resolution referred or in that dealt with by Mr. GAMMELL; and it was probably only the presence of some who were opposed to the original resolution of January 1907 that saved the Council from a vote of censure. In the result Mr. GAMMELL'S resolution was amended by the omission of the word "forthwith" and of the words after "1907," and in this amended form was carried by a small majority. The Council may take the view of this result that they have escaped the vote of censure, but must feel that they have had their knuckles rapped.

OUR curiosity was aroused by the laudatory notices in the non-technical press of Messrs. LYONS'S latest London café, designated "The Corner House," and situated at the corner of Coventry Street and Rupert Street. We read that it was built of Carrara marble and that the main saloon was in the Georgian style with Greek columns and pilasters, whilst the pastrycook's shop was in LOUIS XIII. style. We half wondered whether Professor BERESFORD PITE, in his Euston Square building, which we illustrate to-day, had initiated another Greek revival. We were scarcely disappointed and not at all surprised to find that the Carrara marble was that variety of terra-cotta which Messrs. DOULTON have so successfully introduced under the name of "Carrara," whilst the Greek columns were piers of Greek marble encasing stanchions, and with very distinctive Renaissance Ionic capitals. The whole building is in one style, which can be best described as Restaurant Renaissance, the detail of which is collected from all periods and all countries, some refined and admirable, some the reverse, the most striking idiosyncrasy being the lack of scale in contiguous decorative features. The Mirror Hall in the basement is a fine big room, all lined with marble, save for the mirrors, which are not too obtrusive, and the mosaic in the frieze, which is, and by its garish and bizarre assertiveness quite mars the general satisfactory colour tonality. Despite the lavish use of costly material, the artistic qualities of Messrs. LYONS'S latest establishment are, in our opinion, very much below those of some of their smaller and earlier tea-shops.

THE dangers of petrol have been emphasised during the past week in the daily press, and notably by Mr. WILLIAM HAYDON, the present chairman of the public control committee of the London County Council. It is unfortunate that petrol should be so dangerous, because the new type of petrol lamps would otherwise be of great utility for domestic purposes. It is useless for the manufacturers to put on the market lamps which in themselves are perfectly safe if their employment necessitates the storage of petrol in however small quantities but accessible to domestic servants. Mr. HAYDON neatly says of the ineffectiveness of advice as to the use of petrol in the house, "It is only a shade less mischievous than teaching a child how it may safely play with fire."

VULCAN AND VENUS.—Frieze by J. B. CIPRIANI, R.A.

ARCHITECTURE IN 1908.

A YEAR ago we spoke of the hope existing in the minds of those connected with building that things must soon improve as they could scarcely be worse. That hope has been falsified during the past year and the improvement has not yet commenced. Unemployment in the ranks of both skilled and unskilled workmen during the past year has persistently, month after month, been reported as greater than a year ago. We are told that during the first eleven months of the year the foreign trade, the imports and exports, of this country has diminished by 99,000,000*l*. The credit of the country has scarcely improved, as Consols hover between 84 and 83, although money is undoubtedly cheaper with the Bank rate at 2½ instead of 7.

The most important event of the year in the world of architecture has been the selection of Mr. RALPH KNOTT'S design for the

NEW COUNTY HALL FOR LONDON.

The merits of this design and its most prominent competitors have been fully discussed in the columns of *The Architect*, and it is unnecessary now to reiterate them. The selected design, very slightly modified, has been adopted by the London County Council, and the first steps have been taken towards its realisation. It will be, however, several years before the building as designed will be finished, as a portion of the site is to remain in the occupation of Messrs. HOLLOWAY BROS., whose riverside premises will have to be acquired and absorbed in the complete scheme. The cause of the present limitation of expenditure is, of course, the careful consideration for the financial possibilities of the county of London, that is a prominent feature in the policy of the Moderate party now in power in

THE LONDON COUNTY COUNCIL,

a consideration which has led to the abandonment not only of the ill-starred steamboat enterprise of their predecessors, but also during the past year of the Works Department, that was one of the most cherished fads of the Progressives.

The plausible theory of the existence of an organised ring of contractors, conspiring to keep up the prices of municipal work beyond the limits of fair profit, was not based upon facts, and even had such a ring been a reality, there are more effective ways of fighting the conspiracy than the establishment of a municipal works department, which by the very nature of building business cannot compete successfully with private enterprise. Even supposing, what is extremely rare in municipal employment, that a fair day's work is obtained for a fair day's wage, the municipal department is not in a position to take advantage of the business opportunities that come in the way of an enterprising contractor, and by virtue of which he can always beat a municipal department in the question of expense.

Another branch of municipal trading which has added to its bad repute during the past year is the

HOUSING OF THE WORKING CLASSES.

It may be right that the community at large should provide, in default of private enterprise, healthy homes for the working classes at rents they can afford to pay, but what are we to think of the results shown at West Ham and not unknown elsewhere, that the working classes either will not live in the houses municipally provided, or if they do will not pay their rent? The West Ham Borough Council in this way lost 3,000*l*. in the last year for which the accounts were rendered, and nearly 18,000*l*. since 1901.

The London County Council is to be congratulated and the thanks of the public are due to them for the successful completion of the

ROTHERHITHE TUNNEL,

which should be a valuable addition to the traffic facilities of London, particularly between the eastern and southern districts. It is in the initiation and financing of such public improvements that the activity and energy of municipal bodies is best displayed rather than in the incompetent and costly attempts at municipal trading.

The so-called

MARBLE ARCH IMPROVEMENT

does not redound to the credit of the London County Council from an artistic point of view, and is a muddle which one would carefully avoid showing a visitor from the Continent as an example of what London can do in the way of town planning.

The past year has been the occasion of the biennial

INTERNATIONAL CONGRESS OF ARCHITECTS,

which was held at Vienna in the month of May and was attended by some 1,400 members from all parts of the world. As usual, the papers read were varied in subject, in utility, and in interest, but remarkable for their excellence and avoidance of dulness as well as for their high tone. The social side of the congress appears to have been particularly successful, as might be expected in Vienna, where the cult of the pleasant life is so generally pursued.

In London we have had the

INTERNATIONAL ART CONGRESS

for the Development of Drawing and Art Teaching and their Application to Industries, which besides the ordinary congressional programme of papers and discussions was remarkable for the exhibited collection of the productions of pupils and students of all grades, from that of the Kindergarten and infants' schools to the level of the French Ecole des Beaux-Arts. Wisely the term "drawing" was not supposed to be confined to draughtsmanship on the flat, or, as Professor BERESFORD PITE well expressed it, "lead-pencil and indiarubber." Drawing in the solid in the form of metalwork, wood-carving, and the like was included, and its value recognised as a means of educating hand and eye as well as thought and comprehension. The universal teaching of drawing as a training in thought for and comprehension of the beautiful would be the most potent agent that could be imagined for the advancement of the Mistress Art—Architecture.

Education in architecture having been successfully taken up by such youthful universities as Manchester and Liverpool, it is not surprising that

CAMBRIDGE UNIVERSITY

should think that her position demands that she too should recognise architecture in her curriculum. As it

Digitized by Google

does not appear that design is to form any part of the intended examinations, which are to be confined to technical science and history, the recognition does not go very far and will not make architects, even if it results in adding an intelligent comprehension of architecture to the benefits of university education.

A remarkable wave of thought has been manifest during the past year amongst those who are real educationalists in architecture, and perhaps we should not go far wrong in crediting the inception of this movement to Mr. REGINALD BLOMFIELD. Certainly within one week both Professor BLOMFIELD and Professor REILLY lectured on the same theme of

THE GRAND MANNER IN ARCHITECTURE.

Although Professor REILLY'S lecture was delivered some few days before the first of Professor BLOMFIELD'S, it may have been that the announcement of the latter's course at the Royal Academy suggested a subject to his *confrère*. Whether or not the coincident treatments of this subject were causally connected is, however, unimportant. What is notable is that such a theme should be considered worthy of consideration by two of our leading Professors. And still more, that this should be followed later in the year by the announcement that the Royal Institute has decided to substitute the Principles of Architecture for the detail of the Styles of Architecture, as one of the subjects of its examination.

There can be no doubt that in spite of the protests, both polemical and practical, of some of the more thoughtful minds, the tendency alike of students and exponents of the art of architecture in this country has been during the last half-century towards the exaltation of detail and the disregard of the higher qualities of expression in mass. The era of revivalism both Classical and Mediæval, and its consequent attachment to archæological correctness, has inevitably led to the undue prominence accorded to detail. Revolt against this has been partly the motive force impelling the "new art" movement; but although some of the best spirits in this movement have rightly been led to the proper subordination of detail, too many have fancied the path of freedom to lie in the subversion of the work of the past, and have thereby been led into the vagaries that we have most of us deplored. They are still the thralls of detail, having merely exchanged the chains of correctness for those of eccentricity. That we are now riding on a higher wave of thought in respect to the essentials of architecture is further evidenced by the appreciation expressed of the philosophical paper read by Mr. FELIX CLAY at the Architectural Association on "The Origin of the Sense of Taste in Art." It is surely remarkable that such a paper should be well received in any assembly of architectural students, for in days not so very far back it would scarcely have been tolerated.

Besides the modification of its examination, to which we have above referred,

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS

has during the past year made its application to the Privy Council for the revised charter which represents the effect of the compromise between the educationalists and the registrationists in the ranks of the Royal Institute. During the period of waiting for the new charter several architects have been elected as Fellows under the old system, but this has now practically been stopped by the action of the Associates, who, on a ballot being demanded, promptly black-balled every candidate who had not passed the examination. An attempt was made by the Council to evade the ballot on a subsequent occasion, but was unsuccessful, and the list of candidates for the Fellowship was withdrawn. The new charter has been so long in arriving that it is scarcely surprising that a large number of members of the Royal Institute, Fellows as well as Associates, have firmly resolved that delay, accidental or otherwise, shall not be allowed to nullify the terms agreed upon by all sections as the basis of the new charter. A worthy successor to Mr. LOCKE has been found in the new secretary, Mr. G. IAN MACALISTER, B.A.

THE LIVERPOOL ARCHITECTURAL SOCIETY,

which is the oldest Society outside London connected with the architectural profession, has celebrated the sixtieth anniversary of its foundation. Originally established as an architectural and archæological society, including in its membership those who took merely a *dilettante* interest in architecture, new or old, it gradually became a purely professional body, and such it is now. Professional societies are highly desirable, and one might even say necessary, and the more numerous they become and the more active they are, the better for the art of architecture. But it is not to the benefit either of the art or the profession that associations in which the layman and the amateur can meet with and learn from the actual practitioner of any art should drop out of existence. It is far better for the art that there should be a large body of amateurs and laymen who understand what is good and what is mediocre or bad in architecture, and who can, with an intelligent interest, rightly appreciate the art of the present.

We have plenty of societies for the instruction and benefit of amateurs in archæology, antiquarianism, and even ecclesiology. We need more for amateurs of art in general and architecture in particular.

The science of archæology has cause to mark *cum creta alba* the past year, for this has seen the commencement of the systematic

EXCAVATION OF MEMPHIS

by Professor FLINDERS PETRIE as the representative of the British School of Archæology in Egypt. Many and valuable as have been the results of exploration in buried Egypt, there is good cause to hope that the investigation of the remains of the capital of the ancient empire may be rewarded with even greater treasures and additions to our knowledge not only of the oldest dynasties but of bygone civilisation of comparatively more recent date.

Of both archæological and architectural importance has been the appointment of a Royal Commission to prepare an

INVENTORY OF ANCIENT HISTORICAL MONUMENTS,

for it can scarcely be supposed that when the list is prepared it will simply be pigeon-holed without steps being taken to preserve the value of the list by conserving the monuments that it records.

Failing retention on its original site the fate of the ancient historical monument,

CROSBY HALL,

is perhaps as happy as could be desired. The directors of the Chartered Bank of India, Australia and China offered the fabric to the London County Council, and this body at its meeting on July 14 resolved to accept the gift and to hand it over to the University and City Association of London, who are to re-erect it at Chelsea, convey the freehold of the site and building to the Council, and maintain it for the public benefit, subject to a right of user for the academic purposes of the University Hall of Residence, More House, Chelsea. This solution has superior merit in several respects to the alternative suggestions put forward for its re-erection in the churchyard of St. Botolph's or the garden of Leighton House, not that these latter schemes were without plausibility and adherents.

In the history of our

CATHEDRALS,

the past year has seen the completion of the restoration of the central, or Bell Harry, tower at Canterbury, which has been carried out under the direction of Mr. W. D. CAROE, at a cost of about 15,000*l*. This, however, does not complete the whole of the repair necessary to the cathedral, for during the past year it has been "discovered" that the upper parts of the two western towers are in a dangerous condition and operations have been commenced at a carefully estimated cost of 17,250*l*. for this work. It has also been "discovered" that the piers

Digitized by Google

of the central tower are unsound, cracks, fissures, and crushed stones being evident. These and other urgent repairs bring up the estimated cost to 24,000*l*. It is the same old story once more: the chapters, who are the custodians of our cathedrals, neglect the sustentation of the fabrics under their charge till, as they would have us believe, a sudden and alarming "discovery" is made that a famous and ancient historical monument is on the verge of collapse. It is high time that some public and competent body was formed *ad hoc*, to take over the care of the fabric of our cathedrals and other ancient historical documents.

The guardians of Chichester, having collected and spent 117,000*l*., have appealed during the past year for another 5,000*l*. to "complete" the repair of the fabric, the particular items now urgent being the stonework of the campanile and the lead roof, which is said to be dangerously thin. Completion of the repair is exactly what ought never to be attempted in a cathedral. The fabric should be continually repaired or sustained and never allowed to fall into such a state as to be dangerous.

At Chester they have asked for 6,000*l*. to restore the south-west door and buttress of the south transept and to rebuild the organ. The latter job demands 4,000*l*., but the former work has been put in hand.

The "restoration" of Peterborough Cathedral has been completed and the fund closed after an expenditure of 53,614*l*. exclusive of special gifts. The Dean has started a Fabric Repair Fund. This is as it should be; sustentation and not restoration should be the policy pursued in respect of the fabric of our cathedrals.

At York Minster, too, the restoration of the exterior has been for the present completed, and such repairs as are now necessary will, it appears, be paid for out of ordinary income.

With the north and south turrets and the portal the new west front of Hereford Cathedral has been completed after six years' work under the direction of Mr. J. OLDRID SCOTT.

The choir of Dunkeld Cathedral has been opened for public worship after restoration under Messrs. DUNN & WATSON, at the expense of Sir DONALD CURRIE.

Truro is proceeding towards completion, a contract at 15,369*l*. having been signed for the erection of the western towers and spires.

At Winchester they are still making "discoveries." Having underpinned the two corners of the north transept it has been found that the wall between them must be underpinned also. Another "discovery" is that the buttresses on the wall of the north aisle do not support but hang on to the wall. As this was known to be the case with buttresses at the east end of the church several years ago the recent "discovery" is somewhat belated. A bagatelle of 7,000*l*. has been added this year to the estimated cost of restoration. There is little doubt that, save for sentiment, the proper course to be adopted with Winchester Cathedral would have been to have pulled down the whole building and re-erected it on sound foundations, and by the time the "discoveries" and the repairs are completed it will probably be found that this drastic method would have been the most economical. We only hope that the present faith in the grouting machine is not misplaced, and that it will not be "discovered" that the cement which is supposed to be binding together the fractured walling has found its way into the peat. The grouting machine is used in the construction of tube railways, and the engineers say that by its means the space by which the excavation exceeds the periphery of the tube is filled completely by a waterproof mass of cement so that no subsidence can occur nor water travel along or enter the tube. It is disquieting therefore to know that in the past year the North Lambeth Library has had to be partly rebuilt in consequence of subsidences attributed to the construction of the Baker Street and Waterloo Railway. As we travel on the tubes we see evidences of damp penetrating which lead us to fear that the grouting machine is not so perfect as its sponsors claim.

IMPORTANT BUILDINGS COMPLETED

include the new Government Offices in Parliament Street, designed by the late Mr. J. M. BRYDON; the new Town Hall, Stockport, by Sir A. BRUMWELL THOMAS; the Law Courts, forming part of the new municipal buildings of Hull, and of which Messrs. RUSSELL & COOPER are the architects; the Municipal College, Portsmouth, costing 110,000*l*., and designed by Mr. G. E. SMITH; the extension of Leeds University, designed by Mr. PAUL WATERHOUSE, and opened by H.M. the KING on July 7; the offices of the Royal Pension Fund for Nurses, opened on July 4 by H.M. the QUEEN, and of which also Mr. PAUL WATERHOUSE was the architect. Although not yet opened to the public, Sir ASTON WEBB's important additions to the Victoria and Albert Museum are practically completed. Another large hotel, the Waldorf, in Aldwych, has been added to those of London, the architects being Messrs. A. MARSHALL MACKENZIE & SONS. Mr. J. BELCHER, A.R.A., has added the office building of the Royal Insurance Co., and MAPPIN & WEBB's new premises in Oxford Street to the list of his works in London. A notable piece of design is Professor BERESFORD PITE's new office building for the London, Edinburgh and Glasgow Assurance Co. The new St. James's Hall, Great Portland Street, has been completed at a cost of 100,000*l*., Messrs. JOSEPH & SMITHEM being the architects, and associated with them for the interior Mr. A. BLOMFIELD JACKSON. Mr. LEONARD STOKES has completed the additions to the offices of the Chelsea Borough Council, costing 21,000*l*. A building which has attracted the attention of the general public not for its architecture but for its sculpture is that for the British Medical Association by Messrs. H. PERCY ADAMS & HOLDEN. Amongst the most important hospital buildings completed have been the Royal Infirmary, Manchester, at a cost of 500,000*l*., of which Messrs. E. T. HALL & J. BROOKE were the joint architects; the Booth Hall Infirmary of the Prestwich Poor Law Union, by Messrs. T. WORTHINGTON & SON; the Greenock Hospital by Mr. ALEX CULLEN; the Cardiff City Mental Hospital, costing 349,000*l*., by Messrs. OATLEY & SKINNER; the Glasgow Maternity and Women's Hospital, by Messrs. (the late R.A.) BRYDEN & ROBERTSON; the Infirmary Extension and Nurses' Home at Selly Oak, Birmingham, by Messrs. C. WHITWELL & SON. Churches worthy of note are the first part of St. Wilfrid's Church, Harrogate, by Mr. TEMPLE MOORE, and St. Alban's, Bournemouth, by Mr. G. H. FELLOWES PRYNNE.

IMPORTANT BUILDINGS COMMENCED

during the past year include a new asylum for the county of Essex, the first portion of which, estimated to cost 289,276*l*. and to accommodate 1,376 out of a future total of 2,000 patients, has been begun from the drawings of Mr. F. WHITMORE, the county architect. Another asylum work is the additions to Napsbury Asylum, Middlesex, for which Mr. ROWLAND PLUMBE is the architect, and which is estimated at 91,469*l*. The extension of the Birmingham Municipal Buildings at a cost of 150,000*l*. has been commenced from the designs of Messrs. H. V. ASHLEY & WINTON NEWMAN, selected in open competition. Another successful competition design, that of Messrs. LANCHESTER & RICKARDS for the new home of the Wesleyan Methodist Connexion at Westminster, is now in progress of realisation.

OBITUARY.

The list of architects who have passed away during the year includes the names of Mr. J. S. QUILTER, Mr. F. E. MORRIS, Mr. J. B. COLSON, Mr. E. W. MOUNTFORD, Sir JAMES KNOWLES, Mr. D. R. DALE, Mr. G. A. MANSFIELD, Mr. F. G. JOHNSON, Mr. S. P. REES, Mr. J. LESLIE, Mr. C. F. REEKS, Mr. R. F. VALLANCE, Mr. J. J. STEVENSON, Mr. H. POSTON, Mr. R. C. DAVY, Mr. W. PERKINS, Mr. A. DARBYSHIRE, Mr. H. H. STANNUS, Mr. L. W. GREEN, Mr. T. WINN, Mr. L. H. ISAACS, Mr. F. H. OLDHAM, Mr. A. E. GOUGH, Mr. D. GOSTLING, Mr. F. A. SPRULES, Mr. I. STEANE, Mr. E. TAYLOR, Mr. W. M. FAWCETT, Mr. E. A. GRUNING.

RHEIMS CATHEDRAL—THE CORONATION CHURCH OF FRANCE.

By Professor CHARLES GOURLAY, B.Sc., A.R.I.B.A.

IN no single cathedral in France may one find all the beauties of the French Gothic style which are to be seen in the many ecclesiastical buildings still remaining throughout the country, belonging to the glorious epoch of the thirteenth century. Nevertheless, it is the object of this article to bring before the readers of *The Architect* the claims of Rheims Cathedral to being considered as having approached as near as, and probably nearer than, any other French cathedral, to being truly representative of the work of this great period in France, for it possesses many of the beauties of the style in the highest degree.

The cathedrals of Amiens and Rheims are almost universally considered to be the finest of the great French Gothic structures, and whether Amiens or Rheims is the finer depends on the special feature under consideration. For instance, the interior of Amiens is much higher than that of Rheims and has a lit triforium which Rheims has not, two features which give it a great advantage over that of Rheims, but, on the other hand, the west front of Rheims far surpasses that of Amiens. At Amiens the towers are dwarfed by the enormously high nave, which, being lower at Rheims, enabled the towers to be built in much better proportion with the other features of the façade; therefore the west front of Rheims is undoubtedly the finer one from the strictly architectural point of view, that is, independent of its sculpture, in which it far surpasses that of Amiens. And this superiority extends to the interior of the western façade of Rheims, for there we have a lit triforium below the great rose window, and beneath, on each side of the doorway, the wall face is richly treated with sculpture, set in rows of trefoil-headed niches having intermediate carved panels of the greatest beauty, while the traceried tympanum of the doorway is glazed with old glass; thus the internal treatment is immensely preferable to the blank walling of the interior of Amiens. Hence, although the cathedral of Amiens is often, but not always, preferred as a whole to that of Rheims, yet we may, after these introductory remarks, proceed to the study of the cathedral of Notre-Dame at Rheims—the Coronation Church of France—with the understanding that it holds the proud position of being one of the two finest works of the Gothic period in France or on the Continent of Europe.

RHEIMS CATHEDRAL. PLAN

PLAN.

In plan the cathedral of Rheims is singularly beautiful, being very complete though simple. The nave is long, having ten bays, and it has an aisle on each side but no chapels. The transepts are short, consisting of only two bays, and have one aisle on each side, both of which are wider than the aisles of the nave. Therefore the end bays of the nave and choir arcading at the crossing are wider than the others, thus giving a feeling of lightness and openness at the crossing which is most appropriate. The transepts are placed nearer the east end than is commonly the case in French cathedrals, with the result that the choir fills the crossing and extends westwards into the nave to the distance of three bays. Eastwards of the crossing the choir has three bays, then the apse with its ambulatory and chapels forming a perfect chevet. The chapels are large, being of considerable depth, and the central one is deeper than the others. As to dimensions, this cathedral is exceeded in length externally in France by that of Le Mans only, which has an exceptionally long eastern chapel, the lengths being, Rheims, fully 489 feet, and Le Mans, 492. The length of Rheims internally is 455 feet, and the width of its nave 46 feet.

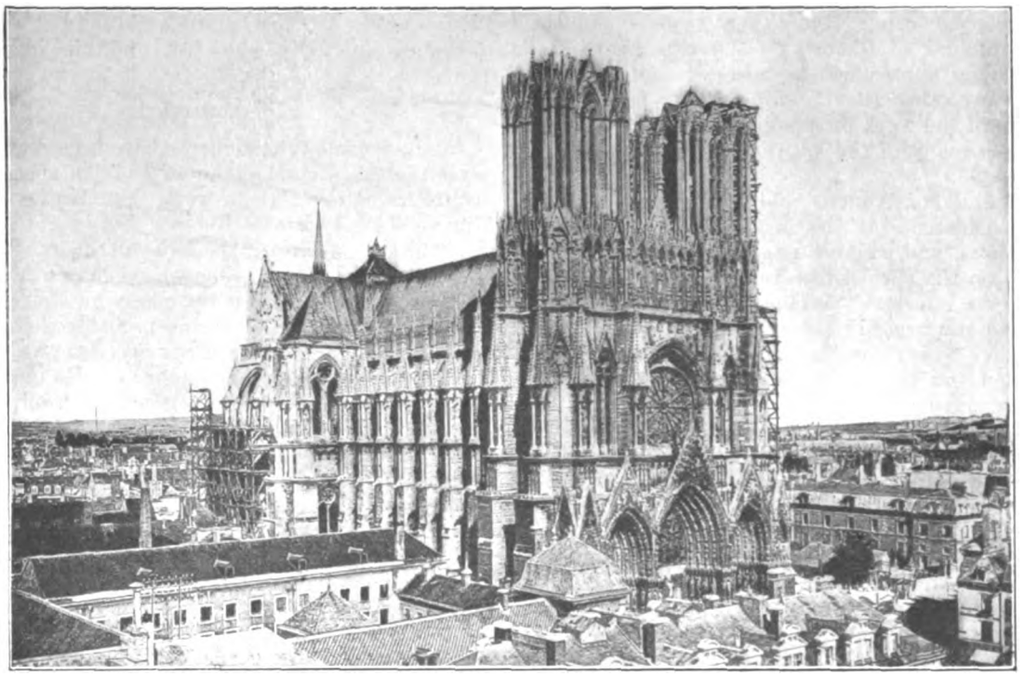
ARCHITECTS.

Many legendary statements have been made about the name of the original architect and his successors, also about the dates of their work, but M. DEMAISON, the Municipal Archiviste of Rheims, has by careful research conclusively established the following facts.

The cathedral of Rheims was begun on May 6, 1211. JEAN D'ORBAIS furnished the plans for the whole building, carrying out the choir and probably the greater part of the transept. His successor was JEAN LE LOUP, who directed the works for sixteen years. He undertook part of the nave, and also the great western front, which was continued by GAUCHER DE RHEIMS from 1250 to about 1260. Following him was BERNARD DE SOISSONS, who constructed the nave from the fifth to the ninth bay inclusive, and the great circular western window. It is known that BERNARD continued to carry on the work till 1287, and that it was, without doubt, very soon after this date that ROBERT DE COUCY became Master of Notre-Dame. ROBERT DE COUCY died in 1311, and therefore he could not, as had at one time been believed, have been the original architect of the cathedral or of its porches. The following parts are attributed to him. The four first western bays of the nave, which, although they harmonise with the other bays, yet show distinct differences in style and in the method of construction. The differences of style may be traced in the profiles of the mouldings and in the carving of the capitals. It is very probable that he was author of the side portions and upper parts of the western front, of which he may have modified the design; also of the towers. At the time of his death the great gallery of the front had not yet received its statues.

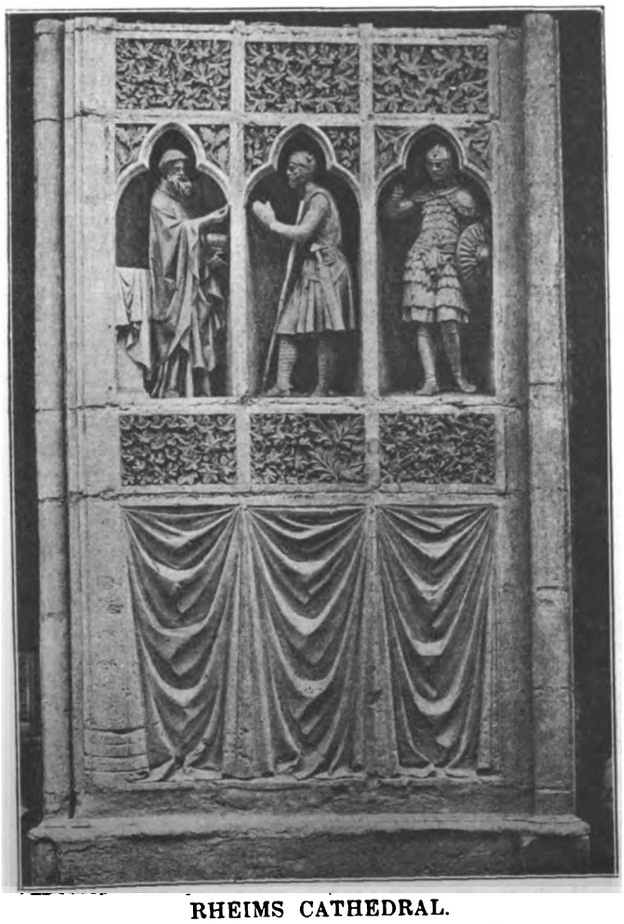
WESTERN FRONT.

Referring to the western front, FERGUSSON says, "The superb west façade is perhaps the most beautiful structure produced in the Middle Ages." Including the towers there are four storeys in this front. The lowest storey contains the three deeply-recessed porches, with gables above each; that over the central porch rises to the height of the centre of the rose window above it. A central pillar divides the great portal into two doors which lead into the nave, while the side porches have single doorways opening into the aisles.



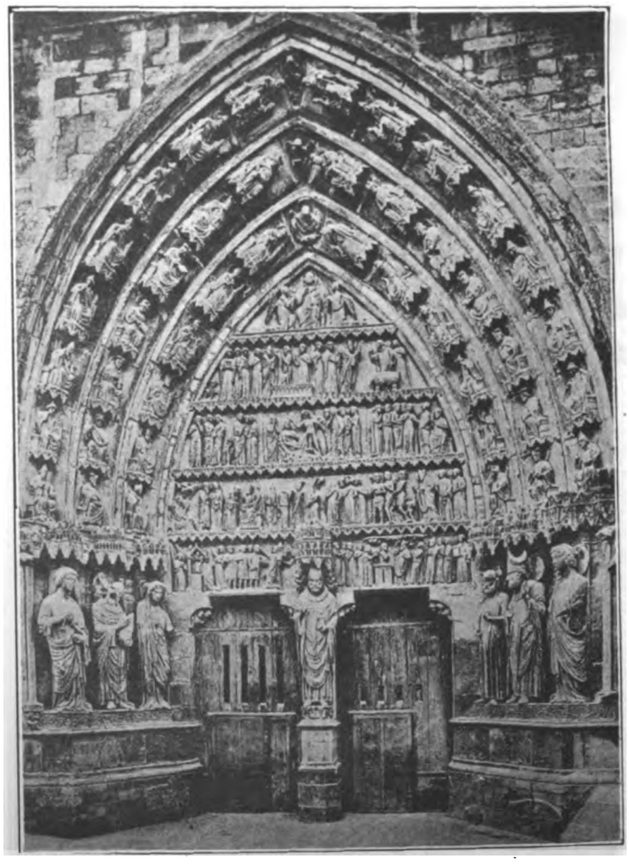
The second storey contains the richly traceried rose window, which is directly above the central doorway and is set in a pointed arched opening. The circle is about 40 feet in diameter, and its bold mouldings make it stand out clearly beyond the plane of the tracery within it. The part into which the circle fits, being square below and pointed above, makes three irregular spaces which have to be filled up somehow. This was commonly done, as in this instance, with tracery, and it is very instructive to observe the many different ways in which it was attempted to satisfactorily solve this problem. On each side of the great rose window are two tall double-light windows, with rich tracery in their heads and gables over.

The third storey contains a fine and effective feature in the gallery containing the row of statues of kings, each statue being placed in a niche with canopy above, which terminates in a small gable, the whole forming a magnificent arcade. The gable marking the centre of the front indicates the roof of the nave but is not directly connected with it, for the roof stops at another gable,



Digitized by Google

which is nearly in line with the eastern faces of the towers, and there is a broad flat space between.



The boldly projecting buttresses divide the façade into three great vertical compartments. The end buttresses are at their bases somewhat similarly treated to the great doorways, having arched panelling with tracery and gables over. The intermediate buttresses rise from between the central and side porches. In the second storey there is a niche containing a statue, with spirelet above, all very richly treated. These buttresses appear to terminate in the arcaded gallery forming the third storey, but their vertical lines are carried upwards into

the towers. The towers themselves form the fourth storey. They are octagonal on plan, having a very tall double-light window on each cardinal face forming the lantern, while projecting from the other sides of the octagon there are polygonal turrets terminating in small pinnacles. These western towers are 267 feet in height and were not completed till nearly 1430; their spires, however, were never executed. It appears as if the spires were not necessary to complete the design of the front, which seems perfect without them. This may be

owing to the irregular outline at the top of the towers, especially the northern one, which is thus in harmony with the rich decoration of the whole front.

This front is undoubtedly a masterpiece; the whole of the architecture is in perfect proportion, and there is a remarkable unity about it which, indeed, is apparent throughout the entire cathedral, just as if one architect had carried out the whole work. The sculpture of this façade is of the highest order, but in this article it is the architectural design which is being dealt with, and the greatest stroke of genius in the design of this front is the arcade forming the gallery of kings, which counteracts the vertical tendency of the buttresses to the extent required, and binds the towers to the central portion, thus producing a perfect composition—indeed, this noble and magnificent façade is unsurpassed.

CENTRAL PORCH, EXTERIOR.

The magnificent central porch is 52 feet high and 20 feet wide, the doorways being 20 feet high. At the base of the façade there is a band of carved drapery with mouldings, above this are statues set on corbels and crowned by canopies, which form a continuous row along the entire front, except on the lintels of the doorways. The lintel of the central doorway was sculptured as those of the north and south doorways still are, though the sculptures on them are greatly mutilated, but that of the central doorway was hewn off in 1793, and in 1802 a commonplace inscription was inserted. The cathedral is dedicated to the Virgin, and the sculpture of this porch all relates to her, while on the central pillar there is a beautiful statue of the Virgin and Child. The tympana of such doorways are generally richly sculptured, but in this example we find the whole of these spaces filled with tracery, that of the central doorway taking the form of a large rose window, which contains beautiful glass. The arch mould is richly carved and its hollows are filled with sculptured figures. Above all, in the gable, there is a group representing the Coronation of the Virgin, capped by a series of niches which follow the slope of the skews. Since mediæval times this porch has been worthily considered one of the four wonders of the Middle Ages in France.

CENTRAL PORCH, INTERIOR.

The interior of this central porch has already been referred to in the introduction. The actual doors are of wood, and the central pillar appears more slender internally than externally, in order to form recessed surfaces, against which the doors may close; the lintel retains its sculpture. The entire tympanum of the doorway, including its circular window and adjoining parts, is filled with beautiful stained glass belonging to the fourteenth century. Perhaps the tympana of the western doorways were glazed in order to admit light for the efficient lighting of the sculpture of the inner face of the wall in which the doors are placed. This sculpture is placed in a series of niches, row above row, and the foliage in the intermediate panels is treated in a very natural manner. In the lowest panels carved drapery is exceedingly well represented. There are in all 120 statues decorating the interior face of this western wall, and there appears to be no other wall interior so richly treated with carving and sculpture. The subject of the statuary on the north side of the central doorway is the Life of JOHN THE BAPTIST, while that on the southern side is the prophecy and fulfilment of the Coming of the MESSIAH.

CENTRAL DOORWAY OF SOUTH TRANSEPT.

The fine central doorway to the north transept is a double one, the opening being divided by a stone pillar with sculpture. This porch is of earlier date than the western ones, yet it is very richly treated with sculpture, that on the jambs relating chiefly to the Bishops of RHEIMS. The tympanum is, here, of solid stone, and it is sculptured in the manner generally followed in similar doorways of this period; the subject is the history of St. NICAISE and St. REMI.

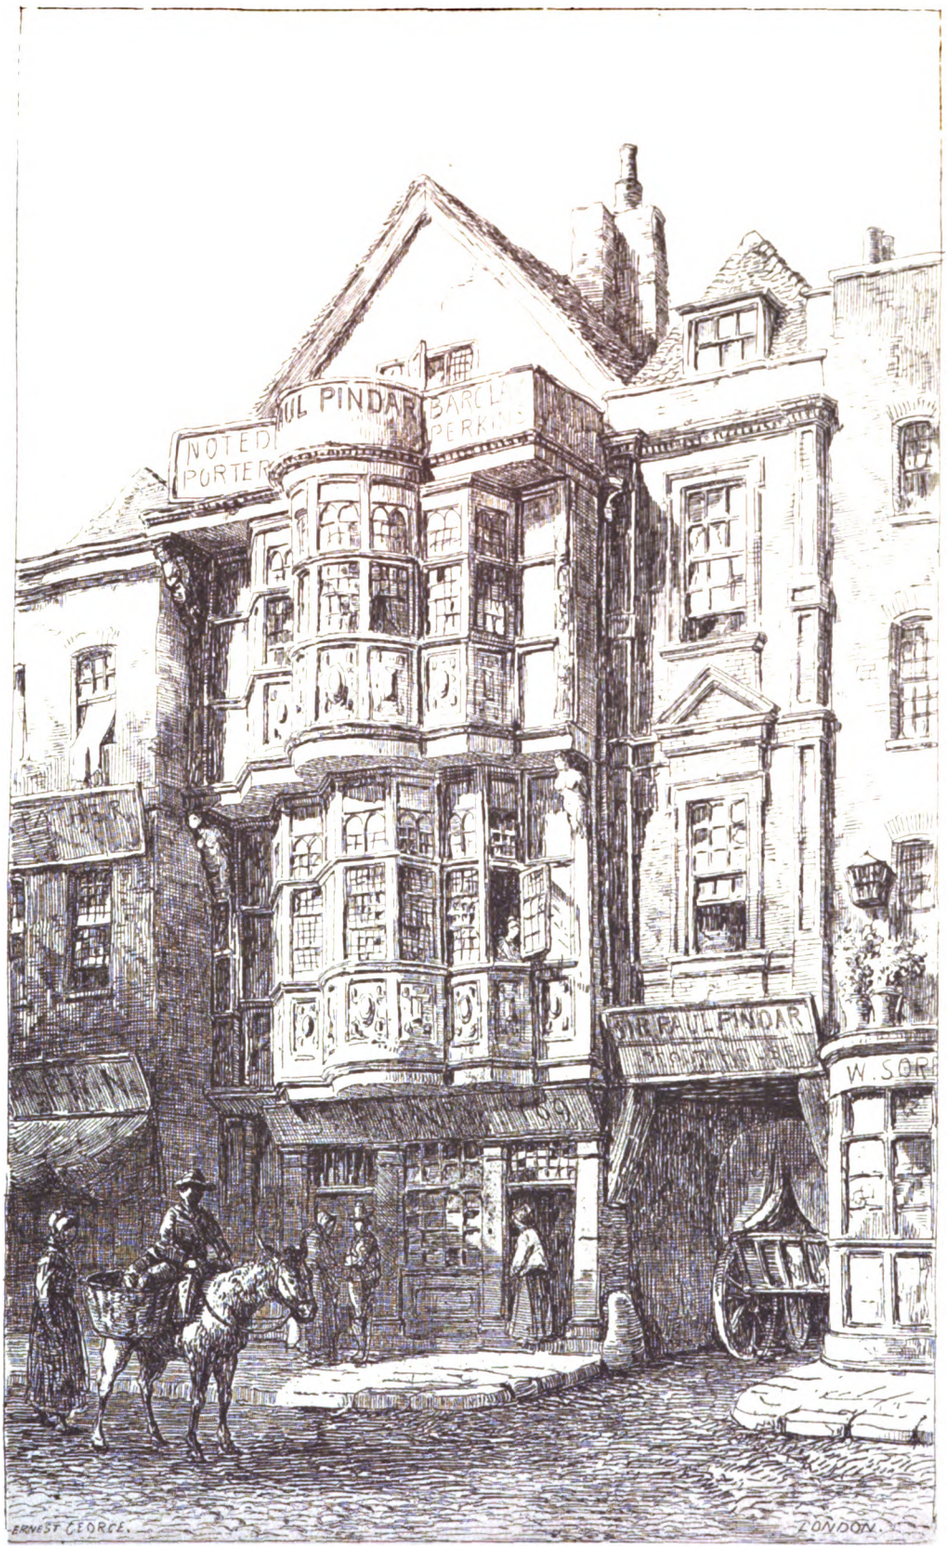
(To be concluded.)

THE WORKMEN'S COMPENSATION ACT (1906) IN OPERATION.—I.

By W. S. HOLDSWORTH, D.C.L.

THE Workmen's Compensation Act (1906) came into operation on July 1, 1907. It has therefore been in force for eighteen months. In some respects it was a new departure, but in most respects it was simply a development of the principles contained in the Acts of 1897 and 1900. In this country Acts of Parliament which introduce a wholly new set of principles into the legal world—Acts like those establishing the limited liability company—are generally in the nature of very rough plans as to the kind of institution or as to the kind of principle which commends itself to the Legislature. The detailed working out of that plan, and the introduction of the necessary safeguards against those who desire to pervert it to their own ends, are left to be provided when cases arise which call for some more specific rules or for some safeguard against hardship or fraud. The problems entailed by the application of a general scheme or principle to the almost infinite variety of the facts of human life are worked out by the Courts in the form of decided cases. This process, like many other experimental processes, is both slow and expensive, but it is sure. Gradually by means of these decided cases and by amending Acts there is evolved what would be called in continental countries a "jurisprudence" of the subject; and finally the results of this "jurisprudence" can be codified into an Act which can lay claim to some finality, because it is no longer a rough sketch or plan of the aspirations of the Legislature, but a considered code based upon the experience derived from concrete cases arising in the world of facts. We have said that the Workmen's Compensation Act, 1906, is not quite a new departure. Though it undoubtedly contains new principles and new ideas, it reproduces in many of its clauses the wording of its direct lineal ancestor, the Act of 1897; and in the ten years which had elapsed between the passing of those two Acts much had been done by the Courts to make the Act of 1897 a workable Act—to give definite meanings to its words and sections and sub-sections, and to determine the extent of the rights and liabilities outlined in it. The Act of 1897 has been repealed, but the judicial labour expended upon it has not been thrown away. Where the wording of the Acts of 1897 and 1906 are identical the old cases still have authority, and therefore the Act of 1906 has worked far more smoothly than it could have worked if it had not had such an ancestor in 1897. Heredity is a force in spheres other than that of biology. But some new principles were introduced by the Act, and all the problems set to the Courts by the passing of the earlier Act had not been fully worked out. It is therefore of some interest to inquire what progress has been made during the years 1907 and 1908 towards the evolution of a definite body of rules upon the subject of workmen's compensation.

The cases decided turn upon many different sections, so that an inquiry of this nature must by the nature of the case be a little disconnected. We shall deal with the subject under the following headings:—The workman's remedies at common law and under the Act; the meaning of the term "accident"; the meaning of the phrase "course of employment"; the meaning of the phrase "serious and wilful misconduct"; questions relating to the amount of compensation payable; questions relating to the rights of dependents; liability for certain diseases; cases turning upon the definition of certain terms.



The Workman's Remedies at Common Law and under the Act.

It is well known that the workman's remedies at common law against his employer for injuries sustained by him in the course of his employment were very inadequate, and that their inadequacy was the main cause for the passing of the Act of 1897. In all cases to which the Employers' Liability Act of 1880 did not apply the workman could be met by the defence of common employment; and in all cases the employer could use ordinary common law defences, such as contributory negligence. The Acts of 1897 and 1906, on the other hand, placed the employer under a statutory liability to compensate for all accidental injuries sustained by the workman in the course of his employment. The mere negligence of the workman is no bar to his claim for compensation. It must be shown that the injury was caused by his own serious and wilful misconduct. But the new rights thus given to the workman did not take away such rights as he had at common law. They were additional, not sub-

stitutional; and occasionally a workman has found it advisable to pursue his common law remedy instead of that provided by the Act. Thus it is provided by the Act of 1906, section 2, sub-section 1, that, in order to support a claim for compensation under the Act, notice must be given as soon as practicable, before the workman has voluntarily left the employment in which he was injured, and within six months of the happening of the accident causing the injury. Therefore if the six months have expired the workman is thrown back on his common law remedies. The Act provides (section 1, sub-section 4) that if a common law action is begun within the six months and decided in favour of the employer, and if it appears that the injury is one for which the employer would have been liable to pay damages under the Act, the Court may, on the application of the plaintiff, assess the compensation due, deducting all costs occasioned by the fact that the plaintiff has proceeded at common law and not under the Act. In the case of Cribb *v.* Kynochs, Ltd.,* a woman gave notice of a claim under the Act. She did not pursue the claim, but sued at common law more than a year after the happening of the accident. This action failed, and she then applied for an award of compensation under the Act. The Court of Appeal held that the claim failed. The Master of the Rolls pointed out that the Act (section 1, sub-section 2*b*) prevented a workman who had failed in his application under the Act from suing at common law, and that, subject to the exception contained in section 1, sub-section 4, it also prevented one who had failed at common law from proceeding under the Act. It was no doubt true that in this case the notice had been given within the six months, but that notice had not been followed up. If a workman could give his notice and then wait for any time he pleased, within the period allowed by the Statute of Limitations, before he made his claim, employers might lose the benefit of the six months' period of limitation. It is only if the period of six months has not expired that the workman who has failed in an action at common law may claim under the Act in respect of the same injury, and then subject to the liability that the costs of the previous action must be deducted from the compensation due to him. Last December, in the case of Cohen *v.* Seabrook Bros.,† where this condition was satisfied, Darling, J., made an award of compensation.

The Meaning of the Term "Accident."

For an authoritative definition of the term "accident" we must look to the case of Fenton *v.* Thorley & Co.,‡ decided under the 1897 Act. This definition was taken as authoritative in the case of Ismay, Imrie & Co. *v.* Williamson,§ which was the first appeal to the House of Lords under the Act of 1906. In the former case the term was defined as meaning "an unlooked for mishap, or an untoward event which is not expected or designed"; but, as the latter case shows, the application of this definition to the concrete facts of particular cases may even divide the House of Lords. In this case a workman who was in a very weak state of health was engaged as a trimmer on board the steamship *Majestic*. While engaged in his work he had a heat stroke, from the effects of which he died. The majority of the House of Lords held that he died from the effects of an accident arising in the course of his employment, and that his widow was therefore entitled to recover. It is true that a heat stroke is a disease, but it was a disease directly caused in this case by the employment on which the man was engaged. It was very similar to the case where a wool sorter, who had got anthrax in the course of his employment, was held entitled to recover. Lord Macnaghten on the other hand considered that, though the injury of which the man died arose out of and in the course of his employment, it did not arise from "accident." The man was in a weak state of health. He was not a trimmer by trade. He did not know what steps to take to ward off the attack. He considered therefore that the injury was the result of the man's own weakness and ignorance, and not of accident. In the case of Broderick *v.* London County Council,‖ the Court of Appeal have reaffirmed the principle that a workman who is working at a dangerous trade, and who is injured by reason of one of the diseases or dangers necessarily attendant on the trade, cannot be said to be injured by an accident. In such a case the injury is not an unlooked for mishap, or an untoward event. Therefore it was decided that where a workman employed in the sewers by the London County Council contracted enteritis by inhaling sewer gas he had not suffered an injury by accident. The distinction between this and the last cited case is somewhat fine, especially if it is true, as some of the witnesses stated, that heat stroke is very common among engineers and trimmers, but can easily be dealt with if proper precautions are taken. It would almost appear that heat stroke is a disease or a danger necessarily attendant on the trade of these persons. But this point does not seem to have been taken in the arguments or in the judgments.

The Meaning of the Phrase "Course of Employment."

It is only if the injury arises from an accident in the course of the injured man's employment that the employer is liable. It is therefore important to know what the Courts consider to be the meaning of this phrase, and on whom the onus of proof rests in a doubtful case of showing that the injury arose in the course of employment. The important case of McDonald *v.* Owners of the Steamship *Banana** clearly decides that the onus of proof is on the workman. In this case a person employed as donkeyman, while returning to the ship, fell off the gangway and was killed. The only evidence as to how the accident occurred was the entry made at the time in the ship's log-book to the effect that Thomas Macdonald, while returning on board ship more or less the worse for drink, refused the aid of the night watchman to assist him up the gangway, and on reaching the top step, over-balanced, fell between ship and quay, and, striking an iron girder, was killed. The County Court Judge thought that the evidence was consistent either with the theory that the deceased had met with the accident in the course of his employment, or otherwise. He thought, therefore, that he could infer that the accident happened in the course of the deceased's employment, and he therefore made an award in favour of his widow. But the Court of Appeal clearly laid it down that the onus of proof is on the applicant, and that if the evidence he produces is equally consistent with the view that the accident did not occur in the course of his employment he fails. As the Master of the Rolls put it† :—"It does not appear (1) whether he had gone ashore on ship's business, or (2) whether he went ashore on a spree without leave, or (3) whether he had leave to go ashore. . . . If he was sent ashore on a ship's errand he would be within the Act. If he went ashore without leave, he would plainly not be within the Act. If he went ashore, not on a ship's errand, but with leave and for his own pleasure, I think he would equally not be within the Act. To give an illustration which possibly appeals to most of us:—If I send my domestic servant in the evening with a letter to a friend, and he is knocked down by a motor omnibus on his way to or from my friend's house, I should be liable. If, however, he, having a night off, goes—as he is at full liberty to go—to the Franco-British Exhibition for his own amusement, and meets with an accident at the same spot, I take it that I should not be liable."

There have been many cases decided upon this subject, and we will shortly state the facts of one or two to illustrate the manner in which they are dealt with by the Courts. In the case of Cremins *v.* Guest, Keen & Nettlefold,‡ the employers of certain colliers, as part of their contract of employment, conveyed them by train from their home to a certain platform reserved for their exclusive use at the colliery six miles off. While waiting for the train one of the colliers was knocked down and killed by the train. It was held that the injury arose in the course of their employment. A workman who is injured while going to the employer's pay-office to receive his pay along a path constructed by the employers for the use of their employés; § a stable employé, who without provocation was bitten by the stable cat while having his lunch; ‖ and an employé of a menagerie, who tried to deal with a lion who had escaped from its cage, and was injured ¶—were likewise considered to have suffered in the course of their employment. On the other hand, an engine-driver, who for his own purposes got off his engine, crossed a siding to get a book from a friend, and was knocked down, was unable to recover.** The Lord Chancellor said :—"I agree that labour is often intermittent.

If a man is in the place of his employment, and during its hours uses such intervals otherwise than in working, and while doing so is injured by one of the dangers to which the employment exposes him, that may be an accident within the statute. He may be in such case required to be in attendance, and in that respect engaged on his duty, though not actually doing work. But here this man was where he was not entitled to be, and was not working, but pleasing himself. . . . The accident did not arise out of, or take place in, the course of employment at all."

The Meaning of the Phrase "Serious and Wilful Misconduct."

Practically the only defence open to the employer based upon the conduct of the workman is the defence that the injury is attributable to the serious and wilful misconduct of the workman himself; and, under the present Act, even the proof of this fact is no defence if the injury has resulted in death or serious and permanent disablement; a workman who wishes both to seriously misconduct himself and to recover compensation must take care that the consequences are sufficiently serious. The onus of proving serious and wilful misconduct is on the employer. The Court must decide as a question of law whether any evidence has been produced from which a reasonable man could find the existence of serious and wilful misconduct. The arbitrator or other tribunal actually trying the case must decide as a question of fact whether the presence of serious and wilful misconduct is to be inferred from that evidence; and, as the House of Lords has pointed out last year in the case of George *v.* Glasgow Coal Company,* such finding of fact cannot be reviewed. All that can be reviewed is the question of law—the question, that is, whether the evidence is of such a kind that a reasonable man could draw from it the inference which has been drawn. We pointed out in *The Architect* of November 23, 1906, that the Courts were inclined to put such an interpretation upon the words "serious and wilful misconduct" that it was in practice very difficult for an employer to avail himself of this defence. Two recent cases, however, would seem to show that a more reasonable interpretation is being given to these words. In the case of Bist *v.* London and South Western Railway,† an engine-driver who, in breach of a rule well known to him, left the footplate while the engine was in motion, got on to the tender and was killed by colliding with a bridge, was held to be guilty of serious and wilful misconduct; and in the case of George *v.* Glasgow Coal Company,‡ already referred to, a man working in a coal mine who, in defiance of a rule, opened the gate fencing the shaft without ascertaining whether the cage had stopped opposite to the gate, though he had been warned against the practice, also failed in his claim for compensation for injury resulting from falling down the shaft. As Lord Atkinson pointed out, the Court must consider misconduct not in a moral but in a business sense. Any breach of a rule is misconduct; the more difficult question is whether it is serious and wilful. "Here the appellant not only broke a rule, but the rule had been brought home to him; he had been warned a few days before of this very matter;" and this, the Court thought, was quite sufficient to justify the inference that the misconduct was serious and wilful. We pointed out in *The Architect*, March 1, 1907, that the permission given to the workman guilty of serious and wilful misconduct to recover if the injury results in death or serious and permanent disablement will be a little difficult to reconcile with the clause which gives the workman the right of recovery if injured by accident, for it is a little difficult to say that the workman has in such a case been injured by accident at all. But this point has not yet come up for decision by the Court.

(*To be continued.*)

[*This series of articles will appear for the next three or four weeks, and will be a concise record of the important cases under the Act.*]

The Glasgow Institute of Fine Arts have appointed the following as hangers for the forthcoming exhibition:—For oils: Messrs. George Houston (painter), John M. Crawford (architect) and Michael Simons (lay member); for water-colours: Messrs. David Gauld and James Kay (painters).

BLAKENEY, NORFOLK. By Harold Oakley.

ROYAL ACADEMY LECTURES—PAINTING.

THE subjects selected by Sir Hubert von Herkomer, C.V.O., R.A., Professor of Painting at the Royal Academy, for his course of four lectures to the students are (1) "Ambition"; (2) "Portraiture," January 7; (3) "The Philistine," January 11; and (4) "Some Personal Experiences," January 14. The first of the series was delivered on Monday afternoon before a crowded audience. Sir H. von Herkomer commenced by warning the students that they would hear many things that might be unpleasant to them, for his lectures were nothing if not admonitory. He had taken as his first subject "Ambition." A journalist who had been very helpful to young men once issued a pamphlet which contained the following dictum:—"Get on, or get off." This certainly did not err on the side of verbosity. It seemed to imply that to get off after a failure was an easy matter. But to an artist, at any rate, that was not true. An artist who fails soon finds that it is far easier to get in than to get out; a love for his art has become engendered in him which not even failure can quench; art has become as essential to his existence as air and breath. He would be content with so little; but even that little is denied him.

Ambition scorns content, its principal characteristic being the right sort of discontent. Without ambition a man sinks into a morass of purposeless effort. Ambition might take many forms, from the acquisition of riches in this world to winning happiness in the next. Ambition needed a stimulus, and no stimulus was so powerful as opposition and rivalry. The artist was fortunate who had to fight in his early years. If success had dropped at his feet ready made it would not have been worth picking up. The artistic life was quest goaded on by ambition; and quest was never still, for no true artist could contentedly rest on the laurels he had won. Ambition remains active longer in the artistic temperament than in any other. Success was something elusive, that seemed to recede as the pursuer advanced to grasp it, and he could never be sure if he had caught it. The artist has no competitor; his goal is never that of another; he lacks the assistance of a pacemaker. In this he is unlike those desirous of achieving fame in physical exercises, where each can exactly measure himself against his neighbour. Yet an athlete has the humiliating knowledge that he cannot run so fast as the ostrich, or jump so far in proportion to his size as the common flea. The artist, however, is fortunate in having no competitor in the animal world. Though there is a handicap on him which is spared to many other callings, if he is not in full possession of his faculties he cannot express his message to mankind. Unless his eye and hand can all faithfully serve him, his art is non-existing. A blind poet can dictate his thoughts; a deaf musician can still compose his immortal harmonies.

Probably nine-tenths of those who enter schools of art are convinced they will become great painters or great sculptors. What a calamity it would be if all those blessed hopes were realised! How cheap would the greatest art become if all succeeded! The first ambition of an aspiring student to be gratified was entering the schools; the second, gaining a medal; the third—the answer must be left to the gods. Ambition has extraordinary vagaries. In a certain Italian campo santo there is a life-size figure of a chestnut-seller carrying a child. The woman whom it represents had scraped together enough money before she died to have a marble monument. Being anxious to see what it would look like, she gave sittings to the sculptor in her last illness. Thanks to her indomitable will she lasted until it was com-

Digitized by Google

pleted, and then as there was nothing more to live for (her life's ambition being realised), and there was no more quest, she died in a few weeks. That was a craving for a kind of posthumous fame. No true artist could say he was indifferent to posthumous fame. It was a tremendous thought, this living on of a man's work, for his worth remained and would represent the essence of his personality. In reading a book by a dead writer you are as deeply impressed as though he were still living in Kensington or Chelsea. It is a wonderful thing to produce a work that is indelible, a work which will be a living factor so long as a fragment of it remains.

Ambition in art being one of the noblest forms of ambition must be also the most beneficial to mankind. There were other kinds which were less exalted. The quest of wealth when normal was healthy, but it was too often made sordid. The miser commits a crime against himself when he denies himself necessaries; the wealthy pauper of whom one often hears commits a crime against the State by living at the public expense. Misers were extraordinary beings. Sir Hubert said he had been told by some friends of his that on one occasion, when staying at a West End hotel, they went for the sake of excitement to a neighbouring fire. As they approached the scene they were met by the usual bustle and disorder of the main thoroughfare. Anxious to avoid the crush, they turned into a side lane, and then seeing a likely-looking door they pushed it open and entered down a dark passage. Their curiosity was undeterred by the smell and filth, and they slowly groped their way along. The sight at the end of the passage sent them quickly back to the street. In a cellar-like room was a dirty old shrunken man sitting at a table before a pile of gold pieces into which he was constantly delving and letting the money trickle through his fingers. The old man was too miserly to put a lock on the outer door, though he was thereby running enormous risks. Turner would not pay for mending a skylight in his studio, though rain was falling on the incomparable works which he meant to bequeath to the nation. He, too, was old and dirty and of a bony frame. Symbolism in art received justification here, for misers were always represented as gnarled old people living in dirt.

Ambition was to be sharply differentiated from notoriety which was begotten by vanity and nourished by approbation. Notoriety could not exist away from the lime-light. A generation ago two brothers sought notoriety and wealth. It was arranged that one should travel the country delivering well-advertised lectures on "The Beautiful in Art," while the other was to use all his influence as a journalist to draw attention on the new prophet. The curiously-attired lecturer was scoffed at and made the subject of public ridicule, but he thereby gained his point, for he was still further advertised and he soon drew a following. Their heaven was reached when the stage took them up. The two brothers had the gratification of finding themselves considerably the richer. In its way the movement did some good in spreading abroad a certain desire for beautiful things.

Every artist knew there were moments in his youth when ambition urged him to efforts to which he had not yet grown, to attempt something beyond him, something which with greater practice and experience he would not dream of touching. That period is far from hurtful. Ambition once started was never likely to be quiescent. The hasty cock-sure phase of a young artist's life when he found fault with all about him is followed by another period when, the scales having fallen from his eyes, he knows not where to turn or what to do. It is then that the student shows what grit he has in him and ambition comes to the rescue by shaking him roughly out of his stupor. Ambition was something far more than a mere desire to supersede another artist, being rather a desire to supersede oneself; and such a craving could never be appeased and certainly never satisfied by the hollow formulæ of complementary stock phrases. All this, said Sir Hubert, might sound like a philosophical dissertation; but it should be remembered that it is impossible to dispense with philosophy and more especially at the present time when the situation requires all a student's thoughtfulness. The rank and file of young artists are born to hard times when things looked most alarming. But they held the balance of the country's art.

One of the chief reasons for this deplorable quandary was that wealth has been turned into the wrong channels, for now it was absorbed in a gamble for Old Masters. Among the present-day rich patronage of art had degenerated from a love of art to pride of price, which now constituted the chief boast of art buyers. The paying of enormous prices for Old Masters had become a duel between two, three or more rich men. Antiquarian value was not art value. This was proved by the variation in prices paid for the same picture—than which nothing could be more illogical. As an instance he quoted the history of Millet's *Angelus*. For this the artist received 40*l*. It was next sold for 72*l*., then for 480*l*., 1,520*l*., 6,400*l*., 22,120*l*., and finally 32,000*l*., at which price it was acquired by an American duellist. A friend of his who purchased pictures of the same school had refused to give 500*l*. for it. The artistic value of a picture is fixed when it leaves the studio, and it was monstrous that art should be utilised for the speculations of the auction room. This pride of price has become a disease. If these enormous prices must be paid then let the descendants of the artist derive some profit; or if there are no descendants the State might devote a percentage of the money to the purchase of works by living artists.

This neglect of contemporary artists was harmful to the community as well as to the individual. It has an enormous moral effect, for nothing is so disastrous to the artist as loafing; it taints his character and his work. Yet the public care as little for the rank and file of the profession as for the unemployed labourer at the dockyard. Rather less, for the labourer can always retire to the workhouse and issue forth again for a day's work without losing caste, whereas nothing so prejudices an artist in the eyes of the world as being out of work. The chance of an artist having a picture hung is very uncertain, and still more uncertain is his chance of getting it sold. There are certainly institutions for enabling them to bridge over bad times, but these doles are immediately swallowed up by pressing bills. Many people had dreams of a remedy for such poverty which would leave no smart of charity behind it.

There were two causes for the existing financial depression in art. One was, as already stated, the pride of price among the rich. The second was a failing interest in art among the English people. Those enormous sums paid for Old Masters did not engender a love of fine art without which no art can live. That love or interest was palpably on the wane. Ask the illustrator, the wood engraver, and the painter of subject pictures, and one and all will tell you that they are more or less out of work. The newspaper proprietors observed the waning interest in art, and followed the movement. The sketcher who knocked off fifty sketches in the time it took a subject painter to produce a single picture had just come into favour. The wonderful and pre-eminent wood engraving of this country was now disappearing before mechanical production, to England's lasting shame. The sketcher was now being supplanted by the camera. Perhaps in one case in a thousand the person appearing in a snapshot might be represented as passably interesting and presentable. In the other nine hundred and ninety-nine cases it was little less than a personal libel against which there was no redress. In accepting snapshots the public were getting a very inferior article in place of the artist's handiwork. He was told on good authority that in America a reaction had set in against this pitiable state of things. All honour to that country.

Another cause of general neglect was the absorbing love of sport. Such a passion will not keep Great Britain in its place in the vanguard of the world. How can a race be improved by twenty, thirty, or seventy thousand men watching a football match, where twenty-two men are doing the work for which they have been trained? Rather they ran serious risks of undermining their health by thus spending their only leisured afternoon in standing about in bad weather. An object lesson was recently afforded by Munich, with its 500,000 inhabitants. There they organised an exhibition of the same size as the Franco-British, which was solely devoted to the arts and industries carried on within its walls. This achievement was in harmony with the general life in Germany. It strikes a note on a modern instrument, though with all the past for inspiration. That inheritance is only abused when we find the house of a millionaire equipped with Louis XV. furniture. The home must be false which is furnished with objects whose proper place is a museum.

The students had certainly fallen on hard times, but for all his gloomy prognostications he did not despair of a reaction before they were fatally hurt. In the halcyon days of his youth artists were few and art lovers many. They must set their teeth and sit tight. They had the gifts of youth, hope, and ambition, and there was need of all. But they must be sure of their strength and innate ability, and that there was something behind those gifts. They must seek first to get on from within, and then afterwards from without. If they failed in both, then get out.

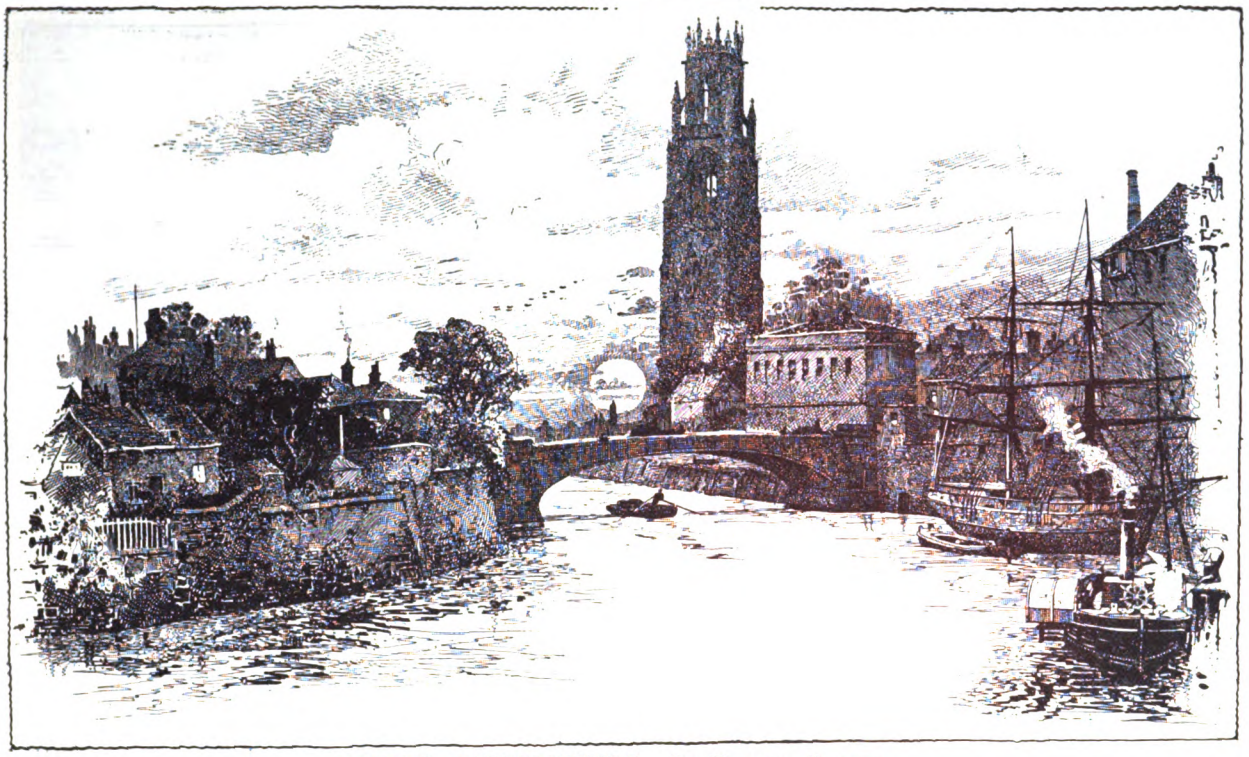
NEPTUNE AND AMPHITRITE.—Frieze by J. B. CIPRIANI, R.A.

NOTES AND THE WEEK.

ANENT the question of "sky-scrapers," it appears that the Building Code Revision Committee of New York City has recommended that in ordinary streets the height of buildings shall be limited to 300 feet, and in streets 45 feet wide to 135 feet, and that even when buildings face open squares and parks the height shall not exceed 350 feet. It is evidently beginning to dawn on New Yorkers that if everyone built to the height of the Metropolitan Life Building life in the streets and lower storeys would be impossible, whilst it is manifestly absurd to allow those who first jump the claim by putting up flatirons to prevent their neighbours from doing the same. In London Mr. HANKEY'S flats sounded the knell of tall buildings, but in America the characteristic admiration of smartness and bigness has till now obstructed the recognition of the inevitable result of unrestrained liberty to the enterprising copyists of the tower of Babel.

THE influence of chinks on the problems of heating and ventilation has been recognised in a general way for a long period by those who have to deal with these problems, but it has scarcely been grasped, as some recent careful investigations show, that these may and do amount to some 10 to 15 per cent. of the window area, so that a window, say 4 feet by 8 feet, may allow a free opening for air of some 4 feet superficial area. Special care in fitting and the use of draught excluders may reduce this amount considerably, but it must not be forgotten that additional provision must then be made for the necessary fresh air in an apartment if one is bent on excluding the draught at this season of the year.

IN the United States they seem to have found, like ourselves, that the system of entrusting the erection of a building to the contractor who submits the lowest lump sum tender for the whole work is not altogether satisfactory, and Mr. FRANK MILES DAY, one of the leading architects of the country, outside of New York, in an address to the members of the Master Builders' Exchange of Philadelphia, advocated six plans for mitigating the evils of the usual system. It must be premised that in the States it occurs that, far more frequently than with us, the general contractor is not himself a real builder, but a financier and smart business man who sub-lets the whole of the work to sub-contractors. Mr. DAY'S first suggestion is that the contractor should be selected for any particular building on the grounds of his high character and experience, not because he happens to send in the lowest tender. Over here many architects have experienced the advantage of this system, and by first choosing their builder and then arranging with him a contract price have found that both their client's interests and their own peace of mind have been thereby benefited. An even better method where a client is willing to pay a fair price for good work is to select the builder and let him carry out the work on the basis of a fixed profit on the prime cost, prime cost in this case meaning the actual cash expended in labour and material *plus* a percentage for establishment charges. The essentials of satisfaction in this latter method are integrity and ability in the builder, and these qualities are in England not difficult to find.



MR. DAY'S second plan is to obtain some control of the sub-contractors by obliging the general contractor to submit, for approval and as an essential part of his tender, the names of his intended sub-contractors. To our insular ideas it seems unthinkable that anything less should be possible, as no British architect would dream of abandoning his own judgment in the selection of sub-contractors or his power of excluding from the work either sub-contractors or actual workmen of whom he did not approve.

THE third suggestion made by Mr. DAY is that the architect should specify the sub-contractors to be employed by the general contractor, or bidder, as he is called in the States. This suggestion, however, Mr. DAY regards as hopeless, for, as he says, "bidders kick against it and will not have it." Naturally, for such a type of business man as the American general contractor or bidder would thus speedily be wiped out of existence. It is an essential part of the system that the bidder should be free to go to the cheapest market both for material and labour, and the only reason for employing him at all is to get the advantage of his ability in this direction. But the system does not make for excellence in building. The fourth plan is but a variant of the third—that instead of the architect specifying the sub-contractors, he should fix the sum to be paid for each section of the work. Equally this also would be fatal to the prevalent system.

MR. DAY'S fifth proposal seems to be that which he himself most favours, the employment of a master builder at a fixed charge or commission, thus turning him into a professional man whose business ability would be exercised in the interest of the client rather than in his own. This is certainly an innovation, subversive of all precedent, that would not be unworthy of consideration in this country if we were less fortunate than we are in having amongst us those who are really master builders as well as men of good business ability and of sound financial position. The professional master builder might readily be found amongst many of those who enter the architectural profession without the artistic capability that is essential to the making of a real architect. He would, however, never be able to compete financially with our present-day contractors of the first rank, who can take advantage of favourable markets to buy and keep in stock material that, although not immediately required, will enable them to submit the lowest tenders for future contracts with the prospect of good profits to themselves. Speaking, as he was doing, to an audience of so-called master builders, one can understand that Mr. DAY should press this proposal as one flattering to their vanity and satisfactory to their pockets, whilst at the same time annihilating the vampire lowest bidder as he exists in the States.

THE last plan put forward by Mr. DAY was that the architect should fill the position of master builder and himself arrange the letting of the different parts of the work to workmen. This, in effect, is nothing else than the system practically universal in Scotland and the North of England, where it is the general custom for the architect to arrange contracts between the client and master-workmen in each trade, mason, carpenter, plumber, and so on through the whole category.

BOSTON, LINCOLNSHIRE.—By HAROLD OAKLEY.

ILLUSTRATIONS.

HOUSE OF SIR PAUL PINDAR, LONDON.

AMONG the many picturesque buildings which have been lost to London is the mansion of Sir PAUL PINDAR, which passed through many vicissitudes before it was finally removed.

OLD HOUSES, EXETER.

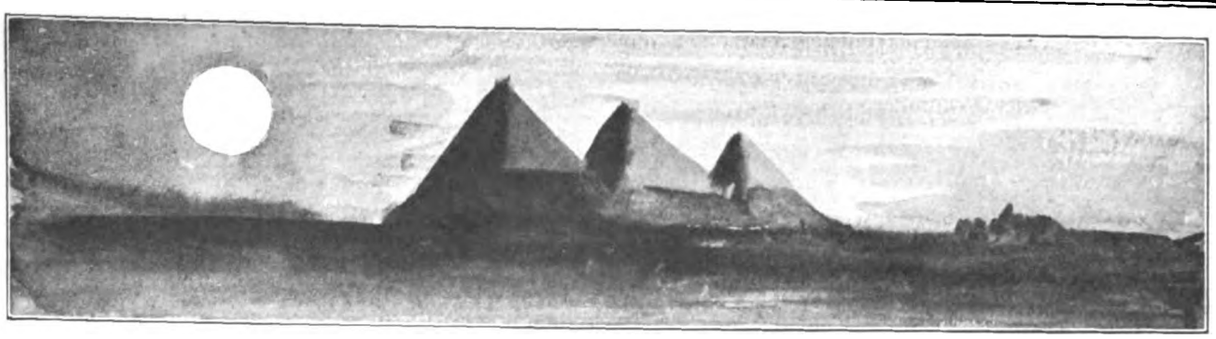
THIS and the preceding illustration show two hitherto unpublished etchings by Mr. ERNEST GEORGE, P.R.I.B.A. In the past Mr. GEORGE has brought out many interesting portfolios. The delicacy of his work is suggested by the present reproductions.

INTERIOR OF CHAPEL FOR GIGGLESWICK SCHOOL.

THE new chapel, designed and built by Mr. T. G. JACKSON, R.A., for Giggleswick School, stands on a rocky eminence in Ribblesdale above the school buildings. It is built of local stones of two colours, red and gray, with dressing of Idle stone for the wrought masonry. The plan is a Latin cross, with a dome over the crossing, covered externally with copper and lined inside with glass mosaic. The mosaic was executed by Messrs. POWELL, of Whitefriars, from sketches by the architect, the figures being designed by Mr. GEORGE MURRAY, a gold medallist of the Royal Academy. The barrel vaults of the arms of the cross are decorated with sgraffito, which was executed by two pupils of the architect, Mr. W. NICHOLLS and Mr. D. STEWART. The chapel is seated with carved pews, and at the west end with canopied stalls for the Masters, which are of Tucoman cedar specially imported from the Argentine Republic. The floor is of marble and the windows are entirely filled with painted glass, executed by Messrs. BURLISON & GRYLLS, the western rose, with subjects of the Creation, being designed by the architect. The carving and marble work was executed by Messrs. FARMER & BRINDLEY; the organ is by Messrs. WILLIS, and the heating and ventilation by Messrs. HADEN & SON. The work was carried out under a clerk of works, Mr. EVANS, without a contractor, the woodwork being executed much to the architect's satisfaction by Mr. BRASSINGTON, of Settle. The whole is a gift to the school by Mr. WALTER MORRISON, of Malham, one of the governors, whose only wish was that the building should be complete in design and decoration, so that nothing should be left for others to do. His gift included a cricket pavilion and a gatehouse, with porter's residence, also designed by Mr. T. G. JACKSON, R.A.

SMALL COUNTRY HOUSES.

THE first design was made for a farmhouse on a gentleman's estate in Essex, the farm buildings already existing. The ground floor to be built of red brick, the upper floor partly half timber and plaster and partly hung with tiles, roofs covered with tiles. The second design was made for a small country house, to be cheaply built. Ground floor, red bricks; upper storey hung with tiles, with half timbered work and plaster in the gables, and roof covered with tiles. The third house was designed to be built with red bricks for the ground floor. The upper floor rough-cast, with a gable of half timberwork and plaster. Roof covered with tiles. The three drawings were exhibited in the Royal Academy. Mr. THOMAS W. CUTLER, F.R.I.B.A., is the architect.



LONDON, EDINBURGH AND GLASGOW ASSURANCE COMPANY'S OFFICES, EUSTON SQUARE, N.W.

THE important British insurance companies are proving themselves to be generous supporters of architecture and the building trades in general. Within the last few years several handsome buildings have been erected by some of our larger companies, and the illustrations from time to time have appeared in *The Architect*. Perhaps one of the finest and most imposing examples is the new block of offices just completed for the London, Edinburgh and Glasgow Assurance Company in Euston Square, London, N.W. The work has been carried out under the supervision and from the designs of Professor BERESFORD PITE, F.R.I.B.A.

LIVING ARCHITECTS.—NO. 1, MR. ERNEST GEORGE.

THESE pen-and-ink drawings, which we purpose giving from time to time, are not to be taken as cartoons as published by some of the journals, but more in the nature of a rapid black-and-white sketch and not a finished drawing.

ARCHITECTURE: ITS TRUE PRINCIPLES.—I.

By R. OWEN ALLSOP.

THE number of definitions of architecture must by this time amount to a very considerable total. To the plain man it would seem an easy matter to define the meaning of the term "architecture." It is probable that from such, rational common-sense views would be obtainable, but the real truth—could we rightly interpret their language—only from babes and sucklings. For it is not to be denied that in proportion as the mind of the philosopher becomes cavernous, so the difficulty increases in obtaining from him a clear definition in terms.

Architecture is unquestionably beautiful building; but inasmuch as abstract beauty has as yet completely defied attempts at concise definition, we can make no great headway on this road. The art of pure architecture is a high

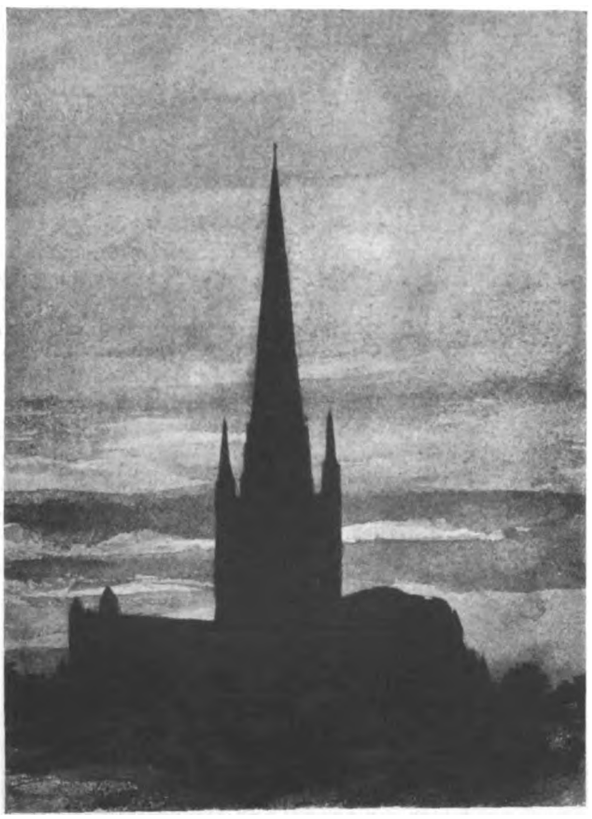

FIG. 1.—NORWICH.

and a difficult one, yet, so hedged about with contradictions is this subject, it is well understood that he who builds artlessly (but well, truly and honestly) makes, or may make, architecture, or at least that which has a savour of true architecture. Again, architects who ponder seriously on the æsthetic side of their lifework have long agreed that we may have building and yet not architecture, albeit that such building may be highly ornamented, or, more properly, profusely covered with ornament, so-called. And all the while, obviously enough, we cannot have architecture without building.

If the writer were required to hazard some additional definition, he might suggest that architecture is a mode or manner simply—a pure abstraction; yet, as it were, so intimately grafted on to the actual entity (building) that no line of junction can possibly be discovered. If we assume that a certain matter-of-fact practical service has to be

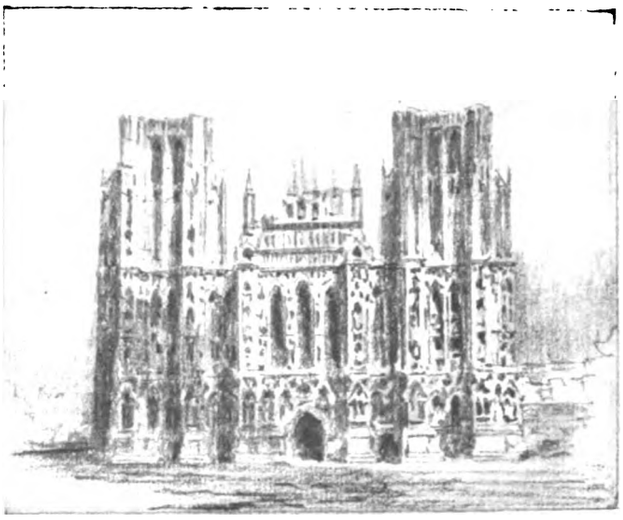

FIG. 2.—WELLS.

rendered, the same may be performed with equal efficiency by one man, a boor in manners, and by another, a refined and cultured gentleman, who epitomises his book of etiquette as "consideration for the feelings of others." If we are here on right lines, then RUSKIN has given one

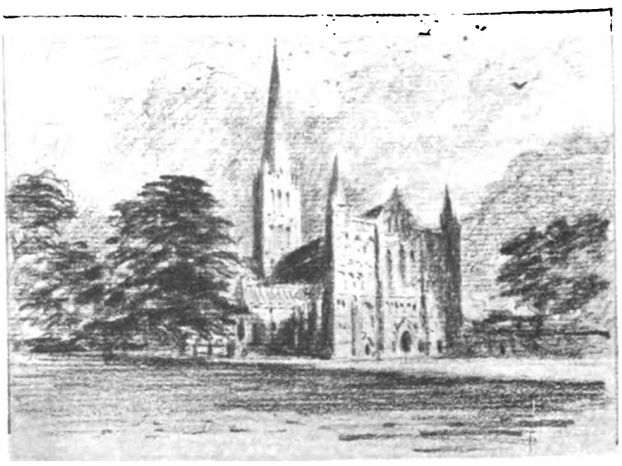

FIG. 3.—SALISBURY.

of the best definitions in his aphorism that architecture proposes an effect on the human mind, not merely a service to the human frame. It is, however, not difficult to see that even here no great logician is required to commence by several approaches formidable attack on this definition of the beautiful in building.

Nevertheless, it were a great step in advance if all could realise that architecture primarily proposes an effect, not merely an exhibition of architectural forms. The ultimate result of architectural design is architectural effect.

Digitized by Google

Broad effects are what we miss in modern architecture, and if it is possible to assign a cause for this it would seem to be primarily the superabundance of detail, or what is called ornament, together with lack of imagination and want of appreciation of the interest arising from the massing of light and shade. In an important competition it was publicly stated by one of the competitors that he had first designed his details and then arranged his composition to suit. A fair analogy would be to select some buttons and then make a coat. All good architecture has good, suitable detail; but architectural detail may be examined in a museum, and cannot of itself produce fine architecture, or, indeed, any architecture at all. It is needed in order to sustain interest. When LUCIUS was initiated as priest of ISIS he wore a rich mantle, "and on whatever part you looked there was something to arrest the eye." The prime components of a work of architecture may be scheduled as (1) outline, (2) composition, and (3) detail. The silhouette of Norwich or of Ely Cathedral against the sky may be interesting, but, if nothing but the bare outline alone is to be made out, the eye, wearied, will quickly fasten upon the varying interest of light and shadow of the sky background. Bald masses then cannot afford a full and complete effect of architecture. The

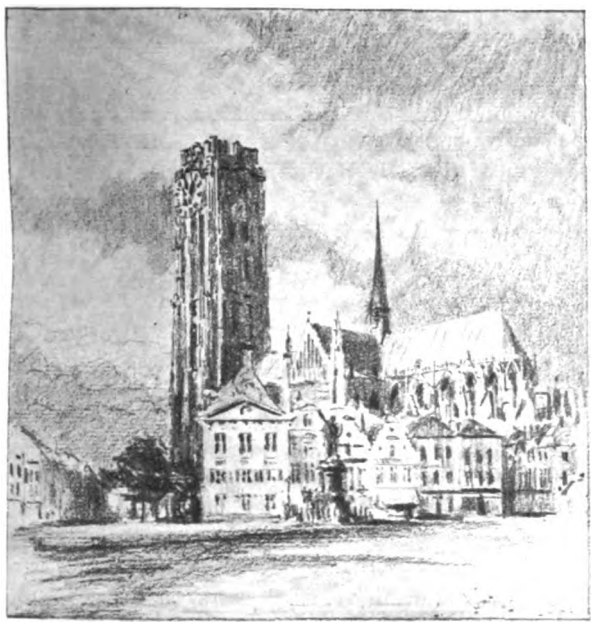

FIG. 4.—MALINES.

analogy is a handsome face and a shallow mind—at first attraction and then weariness at the want of depth of character. Yet, as respects architecture, great masses rearing against a glowing sky constitute beautiful pictures requiring to be duly borne in mind by the architect; for the infinite variation in light and shade effects are not accidents, as they have been termed, but Nature's harmonious accompaniment to man's handiwork. Too much architectural sketching is a matter of lines, as though no sun ever shone in the heavens.

Yet in light and shade is the genesis of architectural effect — a truism generally ignored. The main shadow merely of a building determines its expression—its character; and to take, say, Luxor, it would be only necessary to represent such main shadows and most architects would recognise the group of columns. Expressive lights and shades are the direct result of architectural composition. A similar sketch of the main shadows would be all that would be requisite to indicate Durham Cathedral. For this reason—the expressiveness of main masses—the roughest sketch must, in a building with so definite a character, unfailingly indicate Peterborough. All these effects have nothing to do with detail excepting that such will, as at Wells, give texture in the distant view, or what may be described as subordinate or minor massing—bays, windows, arches, recesses, &c. A spire, such as Salisbury, owes its magnificence not at all to detail, but to the vigour of the component masses. The church at Malines and its surrounding buildings require no detail to suggest the magnificence of the whole group, excepting so far as it breaks up harsh outlines and surfaces. Monochromatic architecture, either internal or external, is primarily the result of the play of light and shade about expressive masses. Polychromy is an added interest—a plus, something over and above. Out of a Cullinan, the cutter produces a sparkling gem, if the stone is moved. As respects architecture, it is ourselves that have to move; and, no doubt, could we have beheld the Parthenon in its glory, and caused the sun to traverse from East to West in a few minutes, the effect would be that, in a sense, a sparkling jewel would be presented to us, and we might think less of elevation and modules however proportioned and deter-

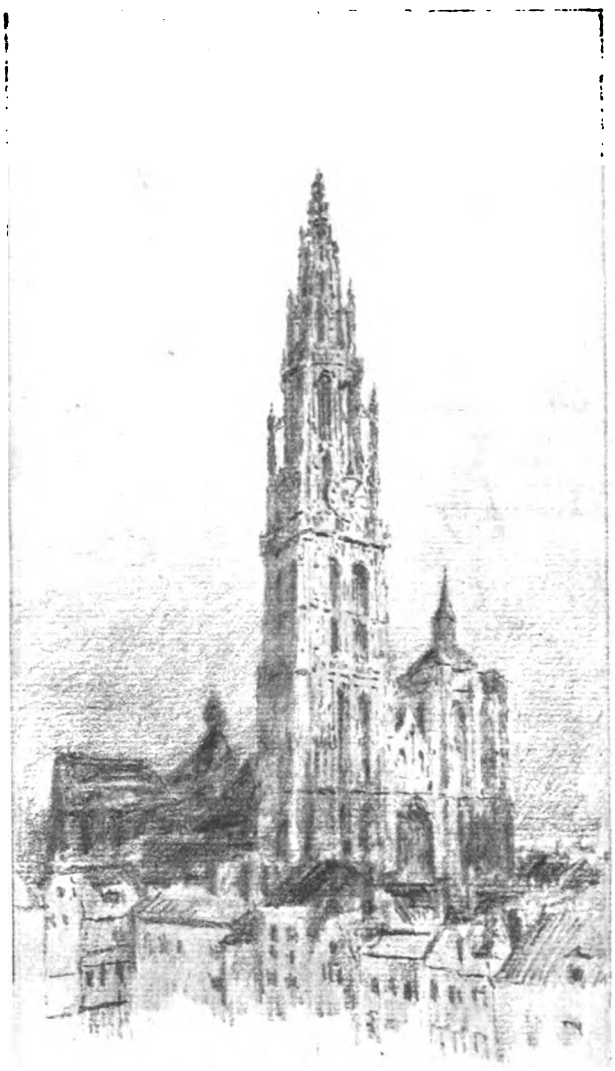

FIG. 5.—ANTWERP.

mined. For of this we may be assured: the fundamental principles of architectural design apply with equal force to the Parthenon and to Salisbury. A style principle teaches us that certain old churches or old temples had columns or arches of this or that shape associated with definite mouldings, definitely proportioned and with certain other necessary accompaniments, while the principles of building tell us that columns must be directed to the earth's centre, and beams defined by circles described from the same centre, if they are to withstand the power tending to destroy their individual existence; and that arches must have abutment. But the principles that lie at the root of the beautiful in building are far deeper and more recondite, and probably of universal application in all art. Immediately we recognise that architectural effect is a matter of form illumined and relieved by the sun's rays we become less concerned about what shape, size, and proportion of forms some old builders adopted, as what forms are of

Digitized by Google

themselves of intrinsic beauty, when gauged in the light of their fitness for their several purposes. We are thus at once driven back on to first principles.

Let it not be imagined that we recommend the abandonment of the consideration of what others have done, and the working out, irrespective of this, new ideas architectural. He who resolves to throw aside precedent and design solely on principles, however fundamental, would well deserve to be called a fool. If clever (ingenious) his resulting work would certainly be interesting, but lack the kind of interest required to be awakened, and his lifework would be eclipsed—for true interest—by the most inexperienced youngster humbly following old traditions. Nor let it be thought that we suggest that a study of erudite principles and first causes will lighten the labour of the architect. Rather will it necessarily increase them, since he will be shamed out of mere copyism. Above all, let it not be thought that we pretend to have discovered any royal road to architectural design. The chiefest of the guiding principles for the architect must ever include hard work, laborious striving and endeavour, toiling and doubling, and that overcoming that brings the promised reward. Without such, so-called first principles will prove a stumbling-block to his destruction.

The fundamental principles of architecture as an art cannot be numerous. EDWARD LACY GARBETT in his endeavour to show that the bulky tomes of measured ancient buildings are nearly useless—as compared with a wide and catholic study of all architecture—has suggested that if we could fully comprehend the significance of the principle of contrast alone, much of the secret of effective architectural design would be revealed. The difficulty arises in the application of a principle to circumstances that are legion and varied conditions that are practically infinite. To know that harmonious contrast is a great basic element of beauty, not only in architecture but in all art, is of little practical use to the designer unless by study of precedent in the light of a lively, inductive reasoning, he can apply the principle to particular circumstance. We may see even that, for example, the great rectangular and cylindrical masses of St. Paul's Cathedral may be compared, as to æsthetic potentiality, with similar forms associated in minute mouldings, but unless we have established views as to the prime cause of resultant effects the knowledge is useless.

When the architect, weary of steel girders and constructional problems necessary to his profession, turns to such a work as the principles of MATTHEW HOLBECHE BLOXAM he reads that in this or that dear old English village church such-and-such an arch-form is associated with this or that group of mouldings. The information gained is as to the principle of a particular style. If he reads elsewhere that buildings should be stable, and form suitable to its practical constructional duty, it may occur to him that the statement is little more than platitude. When, however, he propounds to himself such a question say as the relative æsthetic value of a circle in a triangle or a triangle encompassing a circle, or if he communes with himself as to the art effect of a hemisphere placed over a drum of diameter equal to height or of any true proportion, he at once—by way of geometry and pure mathematics—has opened to him the opportunity of founding his design upon eternal truths—upon laws laid before the foundation of the world.

True architecture—if it is an entity—is the soul of noble building. Its elements are the beauty of suitable form revealed by the sun's rays. The principles of its design are alike binding on an Antwerp spire or the interior of a Santa Sophia. Thus, in both such instances extreme geometrical simplicity characterises the main masses. In the case of the spire this may not seem apparent. It is there, nevertheless, the modelling of subordinate parts giving the appearance of complexity and calling for great structural ingenuity.

Architecture has been called "frozen music." We fear that there is unfortunately round about us much that might be termed "congealed discord."

(To be continued.)

CASTLE D'ARQUES, NEAR DIEPPE.
By HAROLD OAKLEY.

THE SCOTTISH MODERN ARTS ASSOCIATION.

By A. STODART WALKER, Chairman.

THE publication of Mr. JAMES L. CAW's scholarly, illuminative and discriminatory volume on "Scottish Painting, Past and Present," constitutes one of the best possible justifications for the formation of the Scottish Modern Arts Association, organised for the purpose of securing such representative examples of modern Art as an enlightened and experienced committee may deem worthy of preservation in a national collection. One may disagree with Mr. CAW fifty times in his judgments as to the merits of individual painters, but one can agree with him whole-heartedly in his contention that Scottish painting is one of the few original and distinctive manifestations in modern Art, and we can supplement this responsible assertion by maintaining that, at the moment, Art is the most vital and expressive force in the life of the Scottish people. Philosophy may be resting, literature may have few master spirits, and science scarcely living up to its great traditions and records, but never before has Art been so justified by the work of its representatives.

The Scottish Modern Arts Association is the first of its kind formed in this country for such a purpose. "No amount of enthusiasm for the Art of the past," says Mr. CAW, "can foster that of the present. Too frequently, indeed, it is due to fashion or to the prestige created by rarity or costliness, and leads to that superior attitude which finds virtue in nothing that is not old or rare. But all the old is not excellent, and all the new indifferent. The former has been sifted by time, however, and has been appraised by many valuators, while the latter is fresh and unrestrained, and its ultimate commercial value problematical. Further, the certainty of great profits, arising from the high prices now ruling for things of certain periods, has influenced most of the professional dealers and attracted that curious hybrid, the 'dealer connoisseur' who poses as collector and loves Art cheerfully for what he can make by it. Yet, as WILLIAM HUNT remarks in his racy 'Talks About Art,' 'Let us remember that Art, like jelly, has always been

Digitized by Google

more easily recognised when cold. In fact, most people prefer it *canned*. . . . Give me the fellow that can find some honey in the flower that grows!' And one may add that the fellow who sees no good in the Art about him, which embodies the ideals and feelings of his own day, is little likely to appreciate the finest qualities in that of the past."

It was with the object of giving public recognition to the present that I conceived the idea of founding the Scottish Modern Arts Association. Ridding one's point of view of any of the sordid conceptions of ultimate financial value, and being determined to avoid a blind acceptance of the popular favourite as well as the idol of the coterie, and viewing Art purely for its own sake as an individual, expressive, relevant, potent, and inspiring force, the desire was to give the living artist the chance of finding himself recognised by his contemporaries and his work enshrined in a collection, not parochial but national, and while giving the craftsman his due, vastly improving the artistic assets of the nation.

Not being fortunate enough to have possession of such an endowment as that of the Chantrey Bequest, the movement had to be started on a voluntary basis. The system had the great advantage that it was not handicapped by restriction as to the *venue* of purchase or the *personnel* of the selection committee. Being national it could hope to secure, as it has secured, the co-operation of the artists in permitting their paintings to be acquired at a price which might astonish those who have been accustomed to the *largesse* of the Chantrey Fund. Further, the selection committee consisting mainly of reputable laymen of position, intelligence, knowledge, and generous sympathies, there was little danger of the undue recognition of the academic clique or the more privileged few. Of course, there will always be divergence of opinion even amongst great judges. One has only to study such a volume as Mr. CAW's to appreciate the fact of how impossible it is to secure unanimity even about the greater artists. There are men belittled by Mr. CAW whom others, equally competent to judge, place in the very first rank. But granting the limitations to all correct appreciation, the constitution of the Scottish Modern Arts Association promises the most excellent results. And let it not be forgotten that its object is to secure not names but pictures, and that the only claim that can be put forward on behalf of any possible purchase is that it can be recognised as a work of Art.

The ideal aimed at is the removal of an anomaly from the artistic life of Scotland, which finds evidence in the fact that while the Art of the country was never so important or living as it is at present, there is not a single gallery in which one can obtain a comprehensive view of Scottish painting in all its developments and phases. If the encouragement that has been given to the Association increases in the ratio of the past year, the success of this national scheme is assured. One guinea a year constitutes membership, and the contributor will have the satisfaction of realising that he is paving the way not only for a Scottish Luxembourg—representative not merely of the art of modern Scotland, but of England, the Continent, and America—but also to securing that the interests of Scottish Art are looked after in the National Collections in London. This latter endeavour should ensure for the Association a larger meed of support than if its operations had been confined to an improvement of the artistic assets of Scotland alone.

Already the Association possesses twenty important works painted by modern masters. Supporting the Society by enthusiastic endeavour and generous contributions of money are such noted Art patrons as Sir JOHN STIRLING-MAXWELL, Lord BALCARRES, Sir THOMAS GIBSON CARMICHAEL, Sir EDWARD TENNANT, Sir WALTER ARMSTRONG, Sir THOMAS GLEN COATS, Mr. WILLIAM COATS, Mr. HUGH LANE, Mr. ARTHUR KAY, Mr. J. J. COWAN, Mr. JOHN FINDLAY, and Mr. DAVID ERSKINE, M.P. The energy and insight displayed at the initiation of the Association seem an earnest of fruitful results.

CONCRETE AGGREGATES.

THE Special Commission on Concrete Aggregates appointed by the British Fire Prevention Committee have issued an interim report. It will be remembered the executive of the British Fire Prevention Committee have formed among the members of the committee and representatives of the public authorities subscribing to the committee a Special Commission on Concrete Aggregates, the scope of which is described in the following resolution:—"That having regard to the confusion existing as to concrete aggregates, and the absence of their exact specification, the British Fire Prevention Committee do hereby constitute from among its members and subscribers a special commission to report upon and define the aggregates suitable for concrete floors intended to be fire-resisting, having due regard to questions of strength, expansion, and the chemical constituents and changes of the aggregates."

In forming the Commission it has been considered of importance that the various technical interests should as far as possible be represented.

The Commission's work has been divided into two sections in charge of two sub-committees, the one dealing with (*r.t.*) research work and tests, and the other with (*s.*) specifications.

The constitution of the Special Commission is as follows:—Chairman, Sir William Preece, K.C.B.; deputy-chairman, Edwin O. Sachs; chairman of research and tests sub-committee, W. T. Hatch, M.Inst.C.E.; chairman of specifications sub-committee, Max Clarke, F.R.I.B.A.; hon. secretary, Matt. Garbutt, F.R.I.B.A., A.M.Inst.C.E. Representing the Admiralty, C. H. Colson, M.Inst.C.E. (*r.t.*); representing the War Office, Col. A. H. Bagnold, R.E. supt. of building works at Woolwich (*s.*), and Major R. N. Harvey, D.S.O., R.E. (*r.t.*); representing the Norwich Corporation, A. E. Collins, M.Inst.C.E., city engineer (*s.*), H. K. G. Bamber, F.C.S., cement manufacturer (*s.*); F. S. Capon, assistant architect, L.C.C. (*r.t.*); J. Herbert Dyer, senior vice-pres., National Fire Brigades' Union (*r.t.*); F. W. Hunt, F.R.I.B.A., surveyor, Portman estate (*s.*); W. H. Hunter, M.Inst.C.E., chief engineer, Manchester Ship Canal Company (*s.*); Ellis Marsland, district surveyor (hon. sec., British Fire Prevention Committee) (*r.t.*); E. G. Rivers, M.Inst.C.E., chief engineer, H.M. Office of Works (*s.*); Jos. Randall, A.Inst.C.E., contractor (*r.t.*); A. Ross, M.Inst.C.E., chief engineer, Great Northern Railway (*s.*); J. W. Restler, M.Inst.C.E., dep. chief-eng., Metropolitan Water Board (*s.*); Frank Sumner, M.Inst.C.E., city engineer, Corporation of London (*s.*); J. Winn, Lieut.-Colonel, R.E. (*s.*). Chemist to the Commission, Mr. Cecil H. Desch, D.Sc., Ph.D.; assistant secretary, C. Adami.

Research Work Necessary.

The Special Commission has found that the inquiry necessitates tests being made over a period of years before final recommendations can be drafted, and that a further interim report cannot be expected before 1910, and a final report cannot be expected before 1912.

Specification of Materials for Aggregates.

The divergency of views as to the correct description of the actual materials in use as aggregates has, however, led the Commission to the decision of publishing at this stage, with this interim report the schedule A attached, comprising a series of specifications for artificial and natural materials for aggregates frequently used in this country for concrete.

The specifications may be deemed complete with the exception of (*a*) the percentage of sulphur allowable in certain of the artificial aggregates; (*b*) the weight limits for certain volcanic rocks; and (*c*) the porosity of certain clay products, which points can alone be decided after considerable further inquiry and test. The tests necessary prior to framing recommendations should be with concretes in which aggregates complying with the specifications as now drafted alone will be used. The specifications as they stand, even without any recommendations, should be found useful, and may lead to standardisation in the description of aggregates. As to size to which aggregates should be used to fulfil different purposes, &c., these are also matters for which further research is still necessary prior to the recommendations being framed.

Proposed Tests.

Regarding the tests that are deemed to be of immediate necessity, they may be summarised as:—(1) Crushing tests, (2) fire tests, (3) tests as to the holding power of rods in con-

C

Digitized by Google

crete, (4) deterioration tests, (5) expansion tests, and certain chemical tests and analyses.

Seeing that there are fifteen different materials at least to deal with, and that for crushing tests the trials should be at one, three, six, twelve, twenty-four and thirty-six months respectively, the extent of the research necessary is far beyond the time and means available for the Commission to undertake singly. It has thus been deemed advisable that a considerable part of this work shall be distributed among others interested.

The details of the tests have been considered and laid down in a comprehensive manner as a schedule B, which it is, however, deemed premature to publish at the moment, but to give some idea of the extent of the essential tests only it should be stated that allowing for fifteen different materials there will be required at least 750 blocks of concrete for crushing tests, forty-five large slabs for fire tests, 180 special blocks for holding tests, 288 cylinders for deterioration tests, and 216 blocks for expansion tests.

The British Fire Prevention Committee is prepared to undertake the fire tests. The newly-formed Concrete Institute is to be invited to undertake the crushing tests and the tests on the holding power of rods in concrete. Mr. A. E. Collins, M.Inst.C.E., of Norwich, has volunteered to undertake the deterioration tests, and Mr. H. K. G. Bamber, F.C.S., the expansion tests.

Extension of the Reference.

It has been suggested that the reference to the Special Commission should be extended by adding to the word "floors" "and other purposes," whereby the results of the inquiry would probably not only become of greater general utility, but of greater interest to such bodies as the Concrete Institute, to which body the work of the Special Commission may at a later date be most suitably transferred.

Schedule A consists of provisional specifications for concrete aggregates.

A.—Artificial Materials for Aggregates.

1. Coke Breeze.—Coke breeze for use as a concrete aggregate shall be entirely coke taken from the gas retort, coke oven, or special furnace. It shall be absolutely free from clinker, coal, and all substances that will not float in water, and from any admixture of material taken from the retort furnace or water-pan below it, and from cinder, ash, or other admixture. The proportion of sulphur in coke breeze shall not be more than ..... per cent. It was decided that the determination of the allowable amount of sulphur should be the subject of future consideration.

2. Clinker.—Clinker for use as a concrete aggregate shall be the thoroughly burnt and hard waste product of furnaces, free from dust, shale, or free lime, and not having more than ..... per cent of sulphur. Pan breeze is included in this definition. In this case, as in that of coke breeze, it was decided that the determination of the allowable amount of sulphur should be the subject of further consideration.

3. Blast Furnace Slag.—Blast furnace slag for use as a concrete aggregate to be obtained and selected from pig iron smelting furnaces (to the exclusion of basic slag), to be of porous quality, to be washed to remove dust and sulphur, to be without free lime, and not to contain more than ..... per cent. of sulphur. In this case also, it was decided that the allowable amount of sulphur should be the subject of further consideration.

4. Broken Brick.—Broken brick for use as a concrete aggregate shall be from well-burnt and perfectly sound and hard clay bricks, such as London stock bricks, or bricks of equal quality, and shall be of the size specified, and be free from old mortar and from dust or particles that will pass through a sieve of $\frac{1}{8}$ inch mesh.

5. (*a*) Gault Clay Burnt.—Burnt gault clay for use as a concrete aggregate shall be free from free lime and sulphur and from unburnt particles, and shall be thoroughly hard, so that pieces soaked in water for ..... hours shall not disintegrate. It was decided that the tests sub-committee should be asked to determine the length of time to be inserted in the clause. (*b*) Ordinary Burnt Clay Ballast.—Ordinary burnt clay ballast for use as a concrete aggregate shall be free from free lime and sulphur and from unburnt particles, and shall be thoroughly hard, so that pieces soaked in water for ..... hours shall not disintegrate. It was decided that the tests sub-committee should be asked to determine the length of time to be inserted in the clause. (*c*) Broken Terra-cotta.—(1) Porous: Broken porous terra-cotta for use as a concrete aggregate shall be (*a*) from clean and well-burnt earthenware, unglazed, which has been mixed before firing with some combustible material such as sawdust, so that after firing it is of a porous or cellular texture, or (*b*) from clean and well-burnt earthen or stone ware, unglazed, and shall be incapable of absorbing more than ..... per cent. of its own weight of water. It was decided that the tests sub-committee should be asked to determine the percentages to be inserted in these clauses.

B.—Natural Materials for Aggregates.

6. Natural Ballast (Gravel).—Natural ballast for use as a concrete aggregate shall be gravel from river beds, sea coasts or glacial deposits, washed, if necessary, to remove dirt, loam, earthy or saline matter, clay, and other foreign substances.

7. Volcanic Rocks.—All rock of volcanic origin for use as a concrete aggregate shall be entirely free from decomposed parts and must show no signs of expansion, disintegration, or dissolution after having been immersed in water for seventy-two hours. Rocks of this nature may be divided into the following classes:— (*a*) Basalts, traps, dense lavas, &c., weighing not less than ..... lbs. per cubic foot. These shall be dense, thoroughly vitrified, not scoriaceous, show a clean fracture when broken, be homogeneous and free from marked cellular structure. (*b*) Lavas and rocks of similar character weighing not less than ..... lbs. per cubic foot. These shall be hard and free from all soft or organic matter, but they will not be so hard, and will be more cellular than those of section (*a*). (*c*) Pumice weighing not more than ..... lbs. per cubic foot. It shall be hard, free from all organic matter, soft dust or impurity, and show a bright silky structure when broken. It was decided that the tests sub-committee should be asked to determine the weights to be inserted in these clauses.

8. Granite.—Granite for use as a concrete aggregate shall be obtained from ..... (*here insert name of quarry*), and shall be reduced to the specified dimensions by crushing or breaking, and shall be close, hard, and of even texture; free from large crystals of felspar, dirt, argillaceous or organic materials, all decomposed particles, and from dust that will pass through a $\frac{1}{8}$ inch mesh.

9. Sandstones, Limestones, Quartzites, and Rocks of Similar Character.—Rocks of these characters for use as concrete aggregates shall be dense, uniform, and homogeneous in structure and composition. They shall have small even grains and crystalline texture. (This is not intended to exclude oolites otherwise suitable.) Fractures shall be clean and free from large flaws. The weight of the material shall not be less than 130 lbs. per cubic foot, nor its crushing strength less than 200 tons per square foot, and it shall not absorb more water than 8 per cent. of its weight after immersion for twenty-four hours. The aggregate after preparation shall be free from all dirt, decomposed rock, argillaceous and organic material.

With M. Edouard Detaille as its new president, the society styled "Amis de Versailles" is vigorously engaged in making good the deficiencies of State control. The ancient palace is in a neglected condition, and it has become obvious that a sufficient sum is not allotted annually for its proper conservation. The Society, out of its subscribed funds, is now generously defraying the cost of some most necessary repairs to the bases of certain statues which are being carried out under the direction of M. Marcel Lambert, and they propose further to apply for powers to frame rules and regulations which would make the marking of statuary by inscriptions and other petty acts of vandalism a punishable offence. Parliament has voted a sum of 200,000 francs for the conservation of the palace and parks.

The National Eisteddfod of Wales is to be held in the Albert Hall, London, next June, and the arrangements are being pushed forward. The Eisteddfod Association offer a special prize in the arts section of 25*l.*, with a medal, for a catalogue of London works of art executed by Welshmen or relating to Wales. The adjudicators are Sir Marchant Williams, Mr. Goscombe John, A.R.A., and Mr. Christopher Williams. In the general work of the Eisteddfod the adjudicators in the arts section will be (painting) Sir Lawrence Alma-Tadema, O.M., R.A.; sculpture, Mr. J. Havard Thomas; crafts, designs, &c., Mr. T. Erat Harrison; and architecture, Mr. Ernest George, P.R.I.B.A.

HIGHGATE FROM PARLIAMENT HILL. By HAROLD OAKLEY.

STEELWORK.

By C. V. CHILDS, A.M.I.C.E.

IT is hardly an exaggeration to state that steel has of late so pushed its way to the front rank of building materials that it can now claim to be the most important of them all in the construction of modern buildings of any great size and importance. Modern buildings are designed to meet modern requirements; requirements are necessarily limited by possibilities; but, at the same time, one keeps pace with the other, so that the architecture of to-day has to a great extent been revolutionised in consequence of what it is now possible to accomplish by the use of steel in constructional work.

From the artistic point of view, the introduction of steel can hardly claim to have had a beneficial effect on architecture, if by this word be meant only the external appearance of buildings, streets or cities. The so-called "sky-scraper" may be taken as an extreme case of what may be accomplished by utilising the strength of such material as steel in building work; and it would require a large stretch of the imagination to class the modern "sky-scraper" as a thing of beauty. It represents rather utilitarianism run to seed; the beauty of it consists only in the increased amount of rent it can put into its owner's pockets. Fortunately, one has to cross the Atlantic to see these multi-storeyed modern towers of Babel in all their glory; fortunately, too, our building regulations act as an efficient alien law in preventing their crossing the Atlantic and naturalising themselves in our large cities. Who would wish to see the streets of London turned into cañons, with precipitous cliffs of buildings on either side, showing only a narrow streak of sky just visible overhead? Another aspect of such a transformation would be the increased difficulty of the traffic problem. With office buildings whose number of storeys would be reckoned in dozens, each street would be capable of accommodating three or four times its present number of business men; and an aeroplane, instead of a season ticket, would become a necessity to the city clerk.

The influence of steel is not so apparent in English as in American cities; but, nevertheless, it may be detected in many ways. The modern shop, for example, with its eight or more storeys of massive masonry and brickwork, is apparently supported by the plate glass of its shop windows; but the steel is there, though the eye only meets the display of goods reflected in the mirrors that encase the useful but unsightly stanchion. Or, again, one may sit in the spacious banqueting hall of an hotel and never give a thought to the fact that under the gorgeously decorated plaster of the ceiling are buried a few tons of steelwork, that alone prevents hundreds of tons of brickwork from crashing down on to the heads of the feasters beneath.

The tendency of late has been to trust more and more to steel for supplying the strength for the structural stability of large buildings, from the very foundations to the ridge of the roof. Even stone and brick have had to take an inferior place in this respect; the massive stone column or pilaster is no longer what it seems to be—the main support of the superstructure. In many cases it takes no bearing on the ground at all, its sole *raison d'être* being for appearance and architectural effect. It even violates the etiquette of architecture, in that it is a sham. Apparently it is there to do some work, whereas it is only adding a greater burden to the steelwork, to which it clings for safety. Masonry and brickwork have indeed lost their pride of place under these circumstances, and have become decorative rather than constructive materials—the flesh, so to speak, that forms a covering for the bones.

It is only within the last few decades that steel construction has arrived at its present state of development; in fact it is only within that short period that steel itself has come into practical being. Cast iron to a certain extent led the way, even as it did and still does in the process of manufacturing steel. The cast-iron column or stanchion has not been entirely ousted as yet, mainly on account of the fact that it lends itself more easily to decorative treatment than stanchions built up of steel sections..

The cast-iron beam with its unsymmetrical flange has had its day and is passing away to the scrap-yard, as it falls a victim to the house-breaker; its probable destiny, after passing through the furnaces, being to reappear as steel in some shape or form. The despised "Belgian joist," after many revolutions that have affected its manufacture, now aspires to the dignity of the "rolled steel joist," refined in quality and of reliable strength—the most important of all the steel structural shapes employed in building work.

In the early nineties the writer was on the engineering staff of the Carnegie Steel Company, and his duty, amongst other things, was to keep the handbook of structural sections up to date: just at that time the changes came fast and furiously. In the 1889 edition the sections were all tinted blue, representing wrought iron. Then, as new furnaces and works were coming into operation, a general revision had to be made, and the sections in the 1892 edition were mostly parti-coloured—pink and blue—representing that the sections were rolled in either steel or iron. In the 1893 edition the blue had disappeared altogether, steel having completely ousted wrought iron. Simultaneously the price of steel, at first the more expensive, gradually drew level with that of wrought iron, and that at once signed the death warrant of the latter material for rolled structural shapes. The old puddling furnaces, with their costly and laborious methods of manufacturing wrought iron, were swept away, and the Bessemer converter and open-hearth furnaces reigned in their stead.

It was during this period also that the evolution of the steel-framed building was taking place. Its birth-place may fairly be claimed by the city of Chicago, about the last place one would have expected to have inaugurated the type of building known as the "sky-scraper"—Chicago covering probably more superficial area than, and having about the worst subsoil for foundations of, any city in the world. The business area, however, was confined by Lake Michigan and the Chicago river, hence necessity became the proverbial mother of invention. The first problem to be faced was to so proportion the footings of the foundations that the weight of the building should be safely carried on the layer of hard pan overlying the saturated soft clay below the level of the lake.

Steel rails embedded in concrete were first used, in the early eighties, to form the footing course under the masonry walls. At this time, ten storeys was about the limit it was possible to build with solid masonry walls. Naturally the attention of the architects was directed to lightening the weight of the walls; the thickness of the wall had to be lessened and as this depended upon the height of the wall some means had to be devised to split the wall into sections—the smaller in height the better. The natural consequence was the steel-framed building, with thin walls carried on girders at each floor level, the total weight of the building, wall loads, as well as live and dead floor loads, being transmitted through the girders, thence through the shafts to the bases of the stanchions.

Digitized by Google

Having concentrated the entire weight of the building at certain points, the next problem was to so distribute the loads over the footings of the foundations that the pressure on the ground should not exceed what it could safely carry without an undue amount of settlement. Also that whatever settlement of the building was likely to occur, should take place evenly over the whole area of the building.

For this purpose it is necessary to make a distinction between the live and dead floor loads; the live loads being the maximum the floor girders are likely to carry, the total amount of these in a building is considerably more than the total live loads that actually occur. The loads on the internal stanchions are chiefly due to the floor loads of which the live load is a large proportion; whereas the loads on the external stanchions are chiefly due to the weight of the walls and masonry. Consequently in order that there should be an even settlement at every stanchion base, the total dead weight of the structure is the more important and the live loads affect the settlement comparatively slightly. In a city like Chicago where the settlement of high buildings may amount to as much as a foot or more, this matter is of the utmost importance. Perhaps hardly sufficient attention is attached to it in this country; if the area of the footing courses were proportioned more accurately, so as to make the pressure on the foundations more uniform, there would not be so many cracks, which are often apparent in the stone cornices or over the window heads. Such cracks are apt to be attributed to the deflection of the steel carrying the walls, but are far more probably due to uneven settlement at the foundations of the buildings.

Having proportioned the areas of the foundation for the stanchion bases, a further part of the problem was to distribute the pressure at the bases of the stanchions over the area of the footings in the least amount of depth; not only to effect a saving in the excavation, but the primary object at Chicago was to avoid cutting too deeply into the hard stratum overlying the soft one underneath.

Here, again, steel was requisitioned in the form of rolled joist grillages, that is to say, one tier of joists lying side by side placed over and at right angles to another tier, but stepped off so that the area of the top tier gradually increases, until the area of the lowest tier is sufficient to distribute the pressure safely on to the ground; the whole of the steel grillage being surrounded and embedded in concrete.

In this case, too, the concrete which formerly was the constructive material for the foundation courses is relegated to the inferior position of forming a protective covering to the steel.

It may seem that too frequent a reference has been made to what has taken place in the city of Chicago; but it is interesting to notice how the local problems there evolved in a very few years the modern steel frame building, so that practically within a decade, *i.e.*, between the eighties and nineties, the practice in regard to steel structural work for buildings became, so to speak, standardised, and for the last fifteen years hardly any important features have been introduced. Certainly there is the reinforced concrete structure in all its various adaptations for walls, beams, floors, foundations, &c., but that is another story.

(To be continued.)

In Connection with the proposed memorial to the late Sir George Livesey it is announced that at least 10,000*l.* will be required for the endowment of a Livesey Professorship in Gas Engineering and Fuel at Leeds University.

In Connection with the exhibition of designs for small cottages organised by the West of Scotland Garden City Association, 414 Sauchiehall Street, Glasgow, which is to be held early in the year, the following architects have consented to adjudicate:—William J. Blaine, A. Hislop, C. R. Macintosh, A. N. Paterson and James Salmon, jun. The object of the exhibition is to ascertain the best that can be done in Scotland in the way of cheap cottage building, after making full allowance for climatic conditions.

The Hammersmith Board of Guardians having asked the Local Government Board to furnish them with a copy of Mr. Oxley's report on the public inquiry into the cost of the new workhouse and infirmary, have been informed that it is not customary for the Local Government Board to publish the reports of its inspectors. When all the accounts of the new infirmary and workhouse have been settled, the Local Government Board promise to communicate with the Guardians on the subject of the inquiry.

HOLYROOD CHAPEL RESTORATION.

WE are authorised to publish the following correspondence between Mr. Thackeray Turner, Secretary to the Society for the Protection of Ancient Buildings, and Mr. S. Cowan, J.P., member of the Restoration Committee:—

33 Fountainhall Road, Edinburgh:
December 9, 1908.

Dear Sir,—I have read your interesting letter in the *Spectator* of the 5th inst.

I have been quite familiar with Professor Lethaby's report since it came out fully a year ago. This gentleman is a professional not a practical architect, and I do not attach any value to his report in consequence. The Architectural Association of Edinburgh and the Builders' Association of Edinburgh have met and deliberately considered the matter and have resolved unanimously that the Chapel Royal is quite capable of being restored in the terms of Lord Leven's testamentary instructions. I have myself had great experience in building property in Scotland and am familiar with building details. I entirely disagree with Professor Lethaby. His report is far too extreme, far too absolute, when I consider he is dealing with a controversial question.

In company with an architect I went over the ruins very recently and found abundant evidence that the soft stone in the building does not exceed one in five or six and can easily be removed and hard stone put in its place. The walls being off the vertical is of no consequence when you consider they are 10 feet thick. If the last three bays to the east (of the triforium) are formless in respect of mouldings and details there can be no technical difficulty in restoring them to their original condition. It is not impossible to restore the ruins for use as a modern chapel and preserve the ancient architecture. So at least the Edinburgh architects say. To take down the ruins and rebuild would be quite possible. The stones would not break to powder, and I expect that it has the strength and solidity of solid iron. In such event as rebuilding the soft stone would come out easily. If the *north door*, the *west front* and the *west door* have decayed "out of all definite form" there is nothing impossible in replacing them to conform to the original. Mr. Lethaby disapproves of either restoration or rebuilding, and before the Scottish people could agree to this opinion we must have the said report confirmed and verified by properly qualified architects and builders.

The Chapel Royal is the greatest national and historical monument in Scotland and is venerated by Scottish people. Its history has been sparkling and it has been vexatious. Its preservation is an absolute necessity. You raise the general question of restoration such as you have experienced in England, but I am unable to give an opinion on this subject not having inspected any restored edifices there. In Scotland Dunblane and Dunkeld cathedrals have been restored at great expense and by capable architects, and no man can say that the restoration in either case is a disfigurement.—Your obedient servant,

(Signed) SAMUEL COWAN, J.P.

The Society for the Protection of Ancient Buildings,
20 Buckingham Street, Adelphi, London, W.C.

To Mr. Samuel Cowan, J.P. for Perthshire (Member of Restoration Committee).

Dear Sir,—I have very carefully considered your letter of the 9th inst., for which I am much obliged. Your opening assertion that "The Architectural Association of Edinburgh and the Builders' Association of Edinburgh have met and deliberately considered the matter, and have resolved unanimously that the Chapel Royal is quite capable of being restored in the terms of Lord Leven's testamentary instructions," is, however, I am afraid, somewhat inaccurate and misleading. The Builders' Association of Edinburgh, while doubtless an authority on structural matters, can scarcely be accepted as an authority upon questions that are mainly architectural and æsthetic. Further, while the Council of the Edinburgh Architectural Association in committee with architects outside its circle reported upon the structural possibilities as you summarise, they yet also particularly and specifically stated that "they express no opinion on the historic or æsthetic aspect of the question, as such does not fall under the remit." The meaning of this is surely obvious, viz. that upon the most vital, and indeed the only point at real issue, the committee were not agreed, as, indeed, I think was and is an open secret. I therefore submit that in fairness you are not entitled to

Digitized by Google

MORSTON, NORFOLK. By HAROLD OAKLEY.

omit this important and indeed vital reservation and deal only with the portion favourable to your own views.

Again, you state that Professor Lethaby is a *professional* and not a *practical* architect. Apply this reasoning to the legal or medical professions, and please tell me how you differentiate between a "professional" and "practical" lawyer or doctor. Professor Lethaby is an architect and a scholar, and I do not think these qualifications detract either from his ability or acknowledged position. If you are not aware that Professor Lethaby has done a large amount of work, it must be at least within your knowledge that he is surveyor to the Abbey of Westminster, and therefore that the entire fabric of that great building is under his charge.

In your letter to the *Spectator* of November 21 last you speak rightly and reverently of the value of the Chapel Royal of Holyrood, and none can doubt the patriotic spirit impelling your activity. You therein state that, following the Revolution of 1688, "a furious mob of some thousands of persons attacked and looted the Chapel Royal, Holyrood, and burned its entire contents at the Mercat Cross of Edinburgh." That nearly one hundred years later, "another mob broke into the vault of the Chapel Royal, seized all the leaden coffins they could lay their hands on, threw out the dead bodies which were enclosed into the precincts of the chapel, and sold the lead to obtain money. It is not known how many coffins were thus outraged, but the number included James V. and his first wife Queen Magdalen, also Lord Darnley"; and in a footnote you add that "the last restoration of the Chapel Royal in 1758" "was an entire failure." It is at least pertinent to ask what guarantee there is that the restoration presently so ardently advocated will not be an entire failure also. Nothwithstanding all the wanton destruction and desecration you have instanced, is it not amazing that you now deliberately propose to add thereto yet another, and under the specious plea of an impossible restoration to destroy irretrievably all that the vandals of past ages suffered to remain? "Verily ye build the sepulchres of the prophets, and your fathers killed them"; and so "allow their deeds."

You write as if it were indubitably possible to restore the Chapel Royal. I do not for a moment dispute that the structural difficulty can be surmounted, for modern engineering can easily overcome infinitely greater difficulties than any here involved. Where I do join issue with you, and that directly, is that I hold it to be impossible under present labour conditions, and the uncertainty and confusion of architectural styles, either to take down and rebuild, or to cut out and replace the vital and living work of an architectural age, and thereby restore to beauty and architectural fitness by any fatuous modern, mechanical, and forced replica, so dilapidated a building. To insist otherwise is tantamount to asserting that it is possible to scrape down the surface of an old picture, replace four-fifths of the original canvas with new, repaint all in imitation of the original, making up by guesswork what has been destroyed, and thereafter in sanity and truthfulness declare that you have reproduced a work by Raphael or Michel Angelo. Just as reasonable would it be for you, and those who think with you, to claim that you can throw a piece of antique silver into the melting pot, and that the replica you afterwards produce is either the old piece itself, or equal thereto in semblance or value. If for a moment a doubt upon this should arise in your mind, offer the result for sale at Christie's and judge for yourself. Believe me, there is no iconoclast so destructive as he who is consumed by the fervour of ignorance. Would not even the smaller portion of the original and untouched work of a great master be of infinitely more value than any refurbishment or spurious imitation, however costly?

That you personally claim "great experience in building property in Scotland," and "familiarity with building details," is, I am afraid, quite beside the mark, and of no greater real value upon an architectural or æsthetic matter than would be the opinion of any other gentleman of similar building experience.

Further, you frankly say you have no experience of the disastrous result of much of the "restoration" perpetrated in England; and yet as an object lesson it is of a very real value; and I am at some loss to understand why, with issues so important before you as this proposed restoration of the Chapel Royal, you should not only inspect but also carefully study the lamentable results, and learn therefrom to avoid the irretrievable while there is yet time. Surely as well may a voyager refuse to hear of lands he has not seen, or a scientist decline to learn of facts he has not himself observed.

Lastly, that the King's name should be dragged into this controversy is more than deplorable. To ask that His Majesty should become the involuntary adjudicator between two sharply divided sections of his people is neither good breeding nor yet good loyalty, especially when through the recognised official channel a pronouncement has already been made.

We are entirely at one, you, sir, and I, in the desire to retain and perpetuate this valuable monument of Scottish life and history, and to conserve to other generations that most exquisite west doorway, perhaps the most beautiful and unspoilt doorway in these islands; but to cut out and replace what of value remains, to pull down and rebuild, is not to conserve but to obliterate, and if a new Chapel Royal is essential then by all means let it be built, but let not its building or the utilising of even 40,000*l.* be either a reason or an excuse for a destruction which, in the opinion of many, is so wanton and obliterative as that now proposed.

As the subject of your letter and our reply is of public interest, we are intending to send them to the public Press, and in this my committee trust they have your concurrence and approval.—I am, dear sir, yours faithfully,

THACKERAY TURNER, Secretary.

December 19, 1908.

Edinburgh: December 1908.

Dear Sir,—I refer to your letter of 19th inst. In the matter of the Builders' Association of Edinburgh and Leith, that body is undoubtedly an authority on structural matters, composed as it is of many of the most competent and ex-

Digitized by Google

perienced builders in Scotland; and I may remind you that it was on structural matters only that Lord Balcarres and Sir John Stirling Maxwell were entrusted with the carrying out of this part of Lord Leven's will, and they declined to act. No other reason was given by them. It was to show the utter worthlessness of this opinion that the builders took the matter up, and on a subject of this nature their opinion is of the highest importance, if not final.

You set up a new point, and call it "the most vital, and indeed the only, point at real issue." And yet this new point was never disclosed by these gentlemen. The only point at issue with them was the frailty of the structure and nothing else. The Architectural Association, like the Builders', contented themselves with the discussion of the real point at issue, and, as you say, "they expressed no opinion on the historic or æsthetic aspect of the question." You infer from this that they were not agreed on this question, which you admit they did not discuss. In the absence of proper information it is, I submit, neither in your province nor mine to anticipate or conjecture what these professional men said or did at their Holyrood meetings. It is sufficient to know that they decided that the building was capable of restoration.

You give Lord Balcarres and Sir John Stirling Maxwell, and even Professor Lethaby, a slap in the face for which they will probably not thank you when you say that "you do not for a moment dispute that the structural difficulty can be surmounted," and you go on to say, "easily surmounted." These gentlemen have denied this, so we have evidently here a house divided against itself.

When I said that Professor Lethaby "was a professional, not a practical architect," I meant, as he was attached to a college, that he was not an architect, with an office and staff of clerks, drawing plans for the general public and deriving his income from that source. Professor Lethaby only made one visit to the Chapel Royal to enable him to make up his report, and I am not aware that he ever was at Holyrood except on that occasion. That single visit was quite inadequate when we consider that his report involved a bequest of 40,000*l.* and the restoration of the greatest national monument in Scotland. His report has been a great disappointment to the nation, and has evidently caused Lord Balcarres and Sir John Stirling Maxwell to refuse to superintend the restoration. This has been followed up by the First Commissioner of Works intimating in the House of Commons that on account of what had taken place "he had advised the King against the scheme." I don't accept the *ipse dixit* of the First Commissioner of Works as final on a great national question like this. The London Board of Works has for 150 years been the greatest iconoclast that the Chapel Royal has had to encounter. It is out of the question to suppose that "good breeding and good loyalty" are in the remotest degree involved in prosecuting this matter within the sphere of constitutional right.

Because the restoration of 1758 was the work of an incapable or imbecile builder, and the structure fell in 1768, you say it is pertinent to ask "What guarantee is there that the present restoration, so ardently advocated, will not also be an entire failure?" I reply that it is not pertinent to put this question, and it appears to me you are doing a deliberate injustice to Lord Leven's memory by introducing useless caricature into the debate of a great historical subject. Your query is unworthy of your high position as representative of the "Society for the Protection of Ancient Buildings."

Notwithstanding the desecration referred to in my letter you say, "Is it not amazing that you now deliberately propose . . . under the specious plea of an impossible restoration, to destroy what the vandals of past ages suffered to remain?" This question of restoration or non-restoration of the Chapel Royal is matter of opinion. You hold one view: I hold another; while the architects and builders of Edinburgh entirely disagree with you. What, then, are the public to think? Why, simply this, that the architects and builders must be right and you must be wrong. And then your attitude indicates a total want of sympathy with the movement.

You repeat that you "do not for a moment dispute that the structural difficulty can be surmounted, for modern engineering can overcome greater difficulties," and you add the following unintelligible sentence:—"I hold it to be impossible under present labour conditions, and the uncertainty and confusion of architectural styles, either to take down and rebuild, or to cut out and replace, the vital and living work of an architectural age, and thereby restore to beauty and architectural fitness by any fatuous modern mechanical and forced replica so dilapidated a building." What this means I do not make out. It evidently indicates that the labour market is not satisfactory, and that the architectural profession is in a very confused state (*sic*), but what you mean by "cutting out the living work of an architectural age" is incomprehensible. In your view "to insist otherwise is tantamount to asserting that it is possible to scrape down the surface of an old picture . . . repaint all in imitation of the original, making up by guesswork what has been destroyed, and thereafter to declare that you have produced a Raphael or a Michel Angelo." I am entirely opposed, and have been all my life, to the restoration or renovation of oil paintings or pictures, but this comparison you make I do not admit—it is ridiculous. The restoration of the Chapel Royal and the restoration of pictures are as different as light from darkness, and in no sense can either restoration be compared to the other. Further, an architect's profession has no relation to the Royal Academy. A Chapel Royal at Holyrood on a different site is not wanted, nor has it ever been suggested; but what the Scottish people, in my opinion, want, and will prosecute till they have achieved it, is the restoration of the Chapel Royal, with the missing parts replaced in *fac simile*. That is neither vandalism nor the work of an iconoclast, and its result would be a charming illustration of the scientific and æsthetic knowledge and the architectural and antiquarian judgment of the twentieth century.

I do not sympathise with you in your antagonistic position to the proposed restoration scheme, nor do I concur with Professor Lethaby's report. I know the Chapel Royal well, having for half a century been familiar with everything connected with it. If the soft stone is taken out and replaced with hard material that in no way affects the æsthetic features of the ancient building, while it protects it from decay and contributes to the support of the structure. There is no intention of pulling down and rebuilding. The present walls would form an integral part of the restoration, and the building in the hands of a learned architect would be conform to the original so far as that is possible.

We have had several Scottish cathedrals restored within the past few years, and Kirkwall is now being proceeded with. For forty-five years I have been a public man in Perthshire, and during that long period I have never heard a whisper against restoration of these ancient buildings. Had there been any such expression of opinion in that county or in the north I was in a position to hear it. In these circumstances you do not suppose that a learned society sitting in London can control the aspirations of the Scottish people.

The historic aspect of the Chapel Royal to which you refer has been dealt with by me in a lecture given in the Philosophical Institution here on the 23rd inst., under the auspices of the St. Andrew Society, and the audience appeared to be unanimously in favour of restoration.

I agree with your suggestion that this correspondence should be sent to the Press, and I will hand a copy to *The Scotsman*, if you send it to such London newspapers as you think proper.—Your obedient servant,

SAMUEL COWAN, J.P. for Perthshire,
Member Restoration Committee.

Mr. Thackeray Turner,
Society for the Protection of Ancient Buildings.

Mr. Samuel Cowan, J.P. for Perthshire (member of restoration committee), 33 Fountainhall Road, Edinburgh.

Dear Sir,—I am obliged for your letter of the 29th December, and note that you concur with our suggestion that this correspondence should be sent to the Press. In these circumstances, and seeing that we are still unfortunate enough to seem at variance regarding the real matter at issue, viz. the structural *versus* the æsthetic, it would appear useless to prolong the correspondence. Briefly, may I say that the structural of necessity involves the æsthetic, and this Lord Leven's trustees were quick to apprehend. In mediæval days each workman was a craftsman, and there was, broadly speaking, one style of architectural building in every European and Eastern country, indigenous thereto alike in building material, thought and aspiration. To-day there is no architectural vernacular, only illiterate confusion of architectural speech. That "an architect's profession has no relation to the Royal Academy," read in the light of the context, would seem to imply that architecture is not an art. In the days of a living architecture—i.e. when the Chapel Royal was built—there was no divorce between the

Digitized by Google

arts; and, as instanced in the Renaissance of Italy, it was sometimes difficult to say when an artist was most of architect, sculptor, painter, or even poet, as instance Michel Angelo. This union is not only essential, but perfectly intelligible to anyone with even elementary knowledge of or sympathy with art. Lord Leven's trustees grasped the point intuitively. Your own difficulty in apprehending the difference between light and darkness would seem to imply an innate blindness to things artistic, and the "charming" effect of the restoration you advocate would, I am afraid, falsify your aspiration. Hence our desire to conserve unspoilt whatever of good may remain. Your "learned" architect, if he be also artist, would be the first to admit that architecture is not a matter of learning, any more than is poetry a matter of grammar, but that both are the expression and outcome of artistic and poetic instinct and creative power. I am indebted for your frank admission that you do not understand, and pray believe that the ardent desire of my Society is for the preservation, not the destruction, of whatever of even fragmentary beauty may yet remain of the golden heritage bequeathed by the past. Further, to even venture to presume to "control the aspirations of the Scottish people" would be an impertinence; but these aspirations will be at variance with her history and instincts should she elect not to lead, but to follow, in this instance the unfortunate and retrograde example of England.—I am, dear Sir, yours faithfully,

(Signed) THACKERAY TURNER,
January 6, 1909. Secretary.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Plumbing and Plumbers.

SIR,—Although only a plumber (a craft in which to attain success there can be no spare time as a scribe) I desire to plead for a more intimate association between the organisation represented by the Royal Institute of British Architects and the more humble and youthful Institute I have the honour to represent.

That architects see some necessity for association and co-operation with plumbers outside purely business connections is evidenced by the interest shown on the part of distinguished members of that profession in many of the well-intentioned but wrongly directed attempts made by various self-constituted authorities to deal with matters in which architects and plumbers have a more or less equal interest.

It is rather unfortunate that owing to the absence for many years of any representative organisation that could rightly claim to represent this small though no less important department of the building trade, that the architects were decoyed into association with several movements engineered by those whose interest was best served by usurping the representative position the Institute claims, but did not at the same time exercise either its authority or undertake its responsibility, and whose only claim to the necessary financial support (without which they could not exist) lay in the assumption of a title which was the only justification they possessed to interfere in matters quite beyond their abilities to direct.

In proof of this it is unnecessary to more than point out that there remains little evidence of any real improvement which can be directly traced to any association or co-operation between architects and the alien authority which delegated to itself the name and functions of representing plumbers or plumbing.

Whilst there were many architects who joined in movements such as registration, standardisation and other desirable reforms, if on right lines, with the utmost sincerity of purpose, there are not a few whose association in these matters savoured of a clandestine attempt to secure an advertisement or preferment to civic honours at the expense of plumbing, with a varnish of public interest denied to them by the etiquette of their own profession.

It is typical of British gullibility, notwithstanding the past abortive attempts of an alien body like the Worshipful Company of Plumbers, London, that there should still be found architects, whose names and reputation are proof of their sincerity of purpose, to assist that ancient body in its spasmodic attempts to justify its continued existence by interference in matters which the reforming hand of Time has placed far beyond the scope of the original intention of their constitution, the only vestige of which remains in their more ornamental than useful necessity in connection with the civic life of the City.

The most recent sign of activity on the part of this Livery Company, with the usual dispensations of doubtful privileges it assumed to confer to gain support, takes the form of resuscitation of the movement for standardisation of water fittings, but this latest attempt differs from its abortive predecessor in so far that the figure-head is a civil engineer this time, and not as on previous occasions an architect.

It is a hopeful sign that the architectural profession is becoming more cautious, or that a new generation are less easily gulled by the glamour of civic banquets.

In this lies some hope of a closer association, which it is my privilege to plead between my Institute and that to which most of the distinguished members of the architectural profession belong.

It may be pointed out by those who for interested motives desire to deprecate the representative scope of the Institute of Plumbers that we only represent a small portion of the plumbing trade, and that our organisation is largely confined to one part of the country; but when the most has been made of that statement (which we deny) we can justly claim to be the only organisation in existence in this country that has a right to and does take the responsibility of all that concerns the education and efficiency of the craft of plumbing, that we are numerically strongest in those parts of the country where some of the best class of plumbing work is done, and that many of the best of the employers on points of qualification and reputation are included in our membership, and as a last but not unimportant qualification we are plumbers in more than name.

With these credentials we are justified in our desire to be allowed to have the chief voice in all matters which affect plumbers' work and feel equal to all the responsibility which such a position entails.

The joint interests of the architect and the responsible plumber are many, and would require rather a series than a single letter to deal with them.

Most of these interests are of a character which prevents the success of any attempt to deal with them as between individuals or in localities, and can only be effectively secured by joint action between organisations that are responsible and national in character, owing to the necessity which is inseparable from all such arrangements, that the temporary advantages of isolated individuals must be made subservient to the collective interest of the members of each and both the representative organisations concerned and the interest of the general public conserved.

A few of the matters to which brief reference has been made may be enumerated:—Standardisation of building by-laws which affect plumbers' work and sanitation; uniformity of practice and design of the essential parts of all fittings and apparatus used and fixed by plumbers; the much-vexed question of p.c. sums, add for profit and fixing and return of empties; the responsibility of the plumber for the efficiency of the apparatus which comes within his trade, at present often limited to fixing only; direct trading with merchants and manufacturers; and lastly, but not least important, single tendering.

This last subject provides an urgent motive for discussion and co-operation between our respective Institutes, as owing to the somewhat ill-advised acquiescence of the architect to the development of a system of general contracting, which on the face showed an advantage of relieving the architect's responsibility and work but which does not work out in actual practice.

The system introduced a practice commercially unsound, fostered the inefficient and unstable employer of plumbers, and provided the elements of financial ruin to many plumbers whose reputation had hitherto constituted their chief asset, and all this without conferring any real advantage to the architect or his client.

A further development of this universal-provider type of general contractor is now operating against the architect himself, and much of the present stress through scarcity of commissions is due to the cause of this viparious nursling they have fostered, which now employs a draughtsman and dispenses with the professional architect as well as the responsible plumber.

In conclusion, on behalf of the Institute it is my honour to represent, I should welcome an opportunity to meet in conference with the heads of the R.I.B.A. with a view to some co-operation on the points of mutual interest to which

A SACRIFICE TO JUPITER.—Frieze by J. B. CIPRIANI, R.A.

I have referred, and also others which space prevents me enumerating.—Yours, &c.,

WILLIAM CHALLONER,
President Institute of Plumbers, a chief examiner Plumbers' Work Department of Technology, City and Guilds of London Institute.
20 Tothill Street, Westminster, and Blackpool, Lancs.

Commercial Property Dealings, 1908.

SIR,—Under this heading the year 1908 has been somewhat eventful in regard to the disposal of industrial property, principally through the passing of the Patent and Designs (Amendment) Act, August 1907, which became operative in August 1908, the vital clause in the Act being Section 27, as follows:—

"At any time not less than four years after the date of a patent, and not less than one year after the passing of this Act, any person may apply to the Comptroller for the revocation of the patent on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom."

This was the means which affected the foreigner, forcing him, in order to protect his valuable patent rights, to erect works in this country, with the result that large areas of land have been acquired and works erected; also unused factories, previously failing to obtain occupants, were re-opened, some of the property acquired being large areas of land in Cheshire, Buckinghamshire, Flintshire, Cornwall, Hertfordshire, Queenborough, and several sites in London, numerous works in the neighbourhoods of Leicester, Warrington, Enfield, Cheshire, Hertfordshire, and London.

The prices obtained on the average are good and run into many thousands of pounds, a guide to values being as follows:—

London.—Land.—Thameside, from 600*l.* to 1,300*l.* per acre. Canalside, from 450*l.* to 900*l.* per acre. With railway access, from 500*l.* to 900*l.* per acre. Without railway access, from 400*l.* to 700*l.* per acre.

Provinces.—Land.—Waterside, from 400*l.* to 1,000*l.* per acre. With railway access, from 300*l.* to 600*l.* per acre. Without railway access, from 200*l.* to 500*l.* per acre.

London.—Factories.—Newly built, rental 7*d.* per foot floor area.

Provinces.—Factories.—Newly built, rental 5*d.* per foot floor area.

The provincial municipal authorities are keen to make local conditions favourable to the manufacturer, and we know of no restrictive influence against an improvement in value of provincial property, the tendency being to an increase of same, especially regarding land at shipping ports, greater desire being shown by manufacturers to locate on the seaboard.

An improvement in value of London riverside property is looked for on the establishment of the new Port of London Authority. London's area as an industrial centre being somewhat restricted to manufacturers' operations by the London County Council's requirements and other influences, have forced the manufacturer to seek fresh fields and pastures new, with the result that migration has taken place to the country, with lower ground-rent value, more room for expansion, the erection on up-to-date principles of premises on one floor, with modern plant and machinery equipment. These districts have considerably benefited by the erection of works and houses for the workpeople.

In our opinion beneficial results will be very forcibly noticed in England through the passing of the Patent and Designs Act by an impetus to the building trade, the development of land, increased rateable value to local authorities, extra employment of labour, and a general stimulus to trade in the country.

Judging from the inquiries received, we look forward to a continued dealing of factory property, and predict, with the introduction of capital in the country and improvement in commerce, that greater all-round activity will be the result.—We beg to remain, Sir, yours obediently,

LEOPOLD FARMER & SONS,
Surveyors and Factory Specialists.
46 Gresham Street, London, E.C.

GENERAL.

In the Parliamentary Estimates for the current year the following sums appear for the maintenance and protection of ancient monuments in Great Britain and of historic buildings, viz.:—England, 11,275*l.*; Scotland, 2,935*l.*

The London County Council have decided to commemorate, by means of a triangular stone placed in the roadway, the site of Tyburn gallows at the junction of Edgware Road and Oxford Street. His Majesty's Office of Works are about to fix within Hyde Park railings a bronze tablet bearing the inscription:—"Tyburn Tree. The triangular stone in the roadway, 75 feet north of this point, indicates the site of the ancient gallows known as 'Tyburn Tree,' which was demolished in 1760."

Mr. Arthur Hamilton Smith has been appointed keeper of the Department of Greek and Roman Antiquities in the British Museum, in succession to Mr. Cecil Harcourt Smith, on his appointment to the directorship of the Victoria and Albert Museum.

The Autumn Exhibition at the Walker Art Gallery, Liverpool, closed on the 2nd inst. The receipts show an increase of 71*l.* over the previous year. The exhibits sold to the public number 138, the catalogue prices of which amount to 2,069*l.* 19*s.* 6*d.* The catalogue prices of the 181 works sold last year totalled 4,446*l.* 3*s.* 6*d.*, but the Corporation purchases have still to be added to the 2,069*l.* 19*s.* 6*d.* quoted above.

Falmouth All Saints Church Reredos Committee have accepted a design. The general subject is the Ascension, and is to be carried out in stone. The whole work is expected to cost about 600*l.*, towards which 365*l.* has been received or promised.

The Bury Education Committee on Monday adopted the report of the assessor, Mr. John W. Simpson, vice-president of the R.I.B.A., on the competitive designs for the municipal secondary school. Mr. Simpson examined 141 designs, and awarded premiums to the following:—(1) Mr. J. Theo Halliday, Stockport; (2) Messrs. Castle & Warren, London; and (3) Messrs. Appleyard & Quiggin, Liverpool. In commenting on the exhibition Mr. Simpson wrote:—"It is to be regretted that many competitors have not given sufficient attention to the very clear conditions and instructions furnished and to the regulations of the Board of Education, which were also furnished. The somewhat peculiar nature of the site, the difficulty of obtaining fall for the drainage system, and the important questions of aspect and cost, have compelled me in several cases to set aside designs which are in many respects meritorious." The committee will therefore adopt Mr. Halliday's plans and designs.

The Blackpool Town Council have received over 130 sets of plans in the competition for the erection of a central public library on a site fronting to Queen Street and Maybell Avenue. Mr. Carnegie gave 15,000*l.* towards the scheme.

The Architect.

THE WEEK.

THE discoveries made at Glastonbury Abbey during the excavation of the foundations of St. Edgar's Chapel promise to lead up to some rather important data, and Mr. F. BLIGH BOND, in a lecture to the Somerset Archæological Society during the past week, intimated that he expected to prove that the Abbey Church of Glastonbury was the longest ever built in England if not in Europe. An abstract of the paper is given on another page.

THERE is no cause for the public to be alarmed because scaffolding has been put up in front of the west entrance to St. Paul's Cathedral. This does not mean that the building is dangerous, but only that the custodians are, under the guidance of the present energetic and able surveyor to the fabric, Mr. MERVYN MACARTNEY, carrying out their duty to repair, maintain, support and uphold the precious monument entrusted to their keeping—that they are, in short, pursuing the policy that should be followed by all cathedral authorities, of sustentation rather than restoration.

THE exhibition of the work of the leading students of the Royal Female School of Art, conducted by Miss ROSE E. WELBY, and now absorbed by the London County Council Central School of Arts and Crafts, was held on Friday and Saturday last in the new building recently opened in Southampton Row. Naturally we were most attracted by the designs for altar cloths, but we cannot honestly say that these, even that receiving the King's gold medal, were so successful as designs by the students in other directions. There was a lack of ecclesiastical character and an absence of symbolism that, to our mind, are essential in the design of an altar cloth, whilst all the designs fail in the detail of ornament. The designs for chintzes, brocades and other textiles were, on the other hand, admirable, well composed and excellent in their colour schemes. One can readily understand that such subjects would be more consonant with the *métier* of young women students, and doubtless an adequate incentive for their best effort is found in the substantial encouragement afforded by manufacturers, notably Messrs. WARNER & SONS, who have purchased several of the students' designs and produced materials therefrom on a commercial basis. We are pleased to note that students start from the study of the antique, but without the over-elaboration of mere finish in technique that some schools encourage, and that quick work in time-studies is an important part of the curriculum as a corrective to mere industry and a valuable means of cultivating grip and comprehension in an artist student.

WHAT course are the Council of the Royal Institute going to adopt with reference to the resolution passed at the business meeting on the 4th inst.? Will they follow their former tactics and, pursuing the same policy of masterly inactivity, ignore the resolution? Such a course can but result in either a distinct and unequivocal vote of censure or in a determined and probably successful opposition at the next election. The general body of members of the Institute, in a business meeting, has pronounced against limited competitions for public buildings erected with public moneys, and it is futile for some members of the Council to attempt to override this pronouncement because they do not agree with it. The principle of open competitions in such cases may be right or it may be wrong, that is a matter of opinion, and even on the Council itself opinion on this point is not unanimous, for Mr. GAMMELL'S resolution was amended on the proposition of members of the Council and as amended was supported and carried by the help of members of the Council. The great question at issue is therefore this. Is the opinion of some members of the Council, even though they may be the majority of that body, to prevail over the will of the members of the Institute as constitutionally expressed in a general business meeting? If this is so, then business meetings may as well be abolished and all by-laws that give the members of the Institute any voice in the management of their own affairs should be deleted. Surely there are but two courses that, alternatively, can honestly be followed by the Council, either they must accept and obey the mandate of their constituents or those members who are not prepared to do this must resign. Last year there was another course that might have been adopted. The Council might either at a subsequent business meeting or in their annual report have stated that they had considered the question and deemed it unwise to attempt to carry out the resolution of January 1907. They could then have asked the members to reconsider their resolution and demanded a vote of confidence in the superior judgment of the Council. This course for the present Council is now impossible, after they have flouted the will of the members not only in this matter of limited competitions but also in the question of the election of Fellows. The autocratic and high-handed position that the Council has assumed is an impossible one, and the members of the Council that maintain it must either climb down or get out.

THE discussion at the Conference of London County Council school teachers on open-air schools cannot be without interest to architects. The movement in favour of open-air teaching originated in Germany, and appears to have already shown satisfactory results, while it is evident that the idea meets with some favour over here. There is, therefore, another problem for architects to solve, the evolution of a type of building which shall give the advantages of open-air teaching without the inevitable interruption that a liberal acceptance of the term would mean in our climate or collection of weather samples. Open-air teaching could, of course, be combined with the ordinary type of school building, the classes being held in the open in fine weather and indoors in bad weather. The advantages of the new method would, however, be very uncertain and irregular with such an arrangement. The type of classroom suitable for open-air teaching may possibly be found in a modified form of Dutch barn or of such a structure as was shown by the Economic Chalet Company at the Ideal Home Exhibition, a building with protection breast high, with a widely overhanging roof and top light.

THE shrinkage of trade from which this country has suffered during the past year has, we learn from the monthly circular of the British Chamber of Commerce in Paris, been experienced also, though in a lesser degree, by our French neighbours, whose foreign trade has diminished during the first ten months of last year by, in round figures, 16½ millions sterling as compared with the corresponding period of 1907. This is a loss of slightly over 4 per cent. as against our own 10 per cent. diminution. The trade between the United Kingdom and France has fallen by 6¼ millions sterling during the same period, a declension of nearly 8½ per cent. Without entering into any discussion of the part that our fiscal system plays in these unhappy results, it is clear that such figures point to the necessity of increased energy and push on the part of our manufacturers. Whilst the working costs should be reduced wherever possible, the expenditure on publicity should be increased. The man who cuts down his advertisements in slack times will find his share of the diminished trade smaller than ever and will be squeezed out by his competitors who double their advertisements. Architects realise this and enter strenuously into competitions which in busier times they would not touch. Now they are looking round to learn what better and cheaper materials and manufactures are in the market, and they scan with interest advertisements and circulars that would formerly have gone into the waste-paper basket.

THE WINTER EXHIBITION AT BURLINGTON HOUSE.

DEPARTING from the usual custom of an exhibition of the works of old masters, the Royal Academy has this winter presented us with a collection of the work of modern artists, not necessarily an epitome of all that is best in modern art or even representative of what would be in the judgment of present Royal Academicians thus representative, but the collection of a private individual and wealthy amateur. We must suppose that the Royal Academicians by their acceptance and exhibition of the collection of the late Mr. GEORGE MCCULLOCH have endorsed his selection of the works he has purchased, and that they regard his example as one to be followed by amateurs of sufficient wealth, possibly by reason of the principle that Mr. MCCULLOCH appears to have followed, never to buy a picture that had not been painted in his own lifetime. It is as if they would say to wealthy picture buyers, "See how much better it is to buy ten or a dozen modern paintings of excellence or at least sufficiently high quality at a couple of thousand pounds a piece, to live with them and enjoy them, than to pay twenty thousand for an old master which you do not enjoy, but only buy because you have outbid the other fellow." And there is a great deal to be said for this view. The inflated prices of old masters, manipulated largely by the dealers, depend largely upon, first, the rarity of the works, and, secondly, upon the foolish desire to bid more for a certain painting than anyone else has given or is prepared to give. Buying an old master is a good deal like buying a great auk's egg; buying a modern masterpiece endows you with a lifelong pleasure, assuming, of course, that you are a real amateur, and, if you are as well a connoisseur, it may prove also a lucrative investment for yourself or your heirs.

As natural at the Royal Academy, paintings and those principally in oil are virtually the subject of the exhibition, but we enjoyed best the few examples of sculpture, all the bronze examples of which and RODIN'S marble group, "The Kiss," are excellent and delightful. Curious that of the eleven bronzes five are by JOHN M. SWAN, R.A., and there are only two paintings of his in the exhibition.

The most outstanding feature of the collection of 346 pictures is its catholicity, the next the high standard of achievement running throughout the whole. Every phase of that which is best in modern British painting, from LEIGHTON to WHISTLER—not that we thus imply that either is superior to the other—is here represented, and if not the absolutely best work of each man, certainly high-level work of each has been selected. It would, perhaps, be impossible for any individual to collect the absolutely best works of the 194 painters favoured by Mr. MCCULLOCH, even if we could all agree as to which was the best work of each man, or of any one man who was a real artist with an artist's idiosyncrasy, and not a mere machine producing works always of the same field of effort. Take, for example, the works of Sir JOHN MILLAIS: who should say whether "Sir Isumbras at the Ford" or "Lingering Autumn" is the better work? Are they not equally admirable examples of excellent work of a great painter? One can understand that the GEORGE MCCULLOCH who could purchase two such pictures was a man of broad views and catholic appreciation of all that was excellent in modern painting.

Nor, although the work of British painters largely predominates, is the selection confined to that of our own countrymen. Some of the gems of the collection are from abroad, the "Dutch Landscape" of JAMES MARIS and DAGNAN-BOUVERET'S "Dans le Forêt," for instance. DAGNAN-BOUVERET, by the way, seems to have been a favourite with Mr. MCCULLOCH, for there are eleven of his works in the collection, including portraits of Mr. MCCULLOCH himself and of his wife. Speaking of nationality, it is hardly surprising that in the collection of the Glasgow-born millionaire the paintings of Mr. DAVID MURRAY should outnumber by far those of any other individual artist, no fewer than sixteen being here exhibited, including "The Half-Moon" and "Mangolds."

Naturally, most of the Royal Academicians are represented, for it must be admitted, in spite of all cavilling, that the painters in the Royal Academy "forty" are men who have done good work, whatever may be said of their maintenance of the standard to which they have attained or of their superiority to all of those outside the fold.

The notable exceptions are Sir EDWARD POYNTER and Sir HUBERT VON HERKOMER, neither of whom is represented.

Mr. ABBEY'S selected works are "Richard, Duke of Gloucester, and the Lady Anne," and "Lear and Cordelia," both excellent examples of one phase of his work.

Sir L. ALMA-TADEMA is fittingly represented by "The Sculpture Gallery" and his small painting "Love's jewelled Fetters"; Mr. GEORGE CLAUSEN by his early works, "The Little Haymakers" and "Ploughing," and his later production, "Going to Work." Mr. DAVIS is seen in "A Gleaming Day in Picardy," "Loch Maree," "Now came still Evening on," and "Summer-time."

Of Mr. FRANK DICKSEE'S work there is only one example, but that is a fine one, if somewhat theatrical, "The Burial of the Viking." Sir LUKE FILDES also is represented by only one picture, "The Alfresco Toilet." Two of Mr. GOW'S historical pictures are to be seen, "After Waterloo—Sauve qui peut" and "After Langside—Queen Mary's Farewell to Scotland," one of his best. Mr. PETER GRAHAM'S pictures appeal to a Scotchman above all lovers of fine painting, and we have before us "Where Gannets Build," "The Hamlet by the Sea," "Caledonia Stern and Wild," a great work; "A Highland Glen," also admirable; and "Evening-time." Mr. GREGORY is represented by a single work, "The Old Wedding Gown." There are four examples of Mr. LEADER'S popular landscapes, "Mead and Stream," "Worcester Cathedral," a charming picture; "When the Sun is set; a Worcestershire Village," and "Conway Bay and the Carnarvonshire Coast." By Mr. SEYMOUR LUCAS there is but one picture, but a worthy one, "The Call to Arms."

More Scotch is seen in Mr. MACWHIRTER'S excellent works, "A Highland Bay," "The Sleep that is among the Lonely Hills," and "A Spate: Glen Affaric." To Mr. DAVID MURRAY'S sixteen paintings we have already referred.

Sir QUILLER ORCHARDSON is to be seen at a high level in "Music, when sweet Voices Die, Vibrates in the Memory," "The Young Duke," "Blossoms Fair," and one of the best pictures in the collection, "Master Baby." Mr. BRITON RIVIERE is one of those of whose work there is only one example, and that not of his best, "So Near and yet so Far."

Mr. SARGENT'S art is seen in six pictures, and amongst them some of his best work and some of the best paintings in the collection. "On his Holiday: Salmon-fishing in Norway" and a sketch with the same title; "Portrait of the late George McCulloch, Esq."; "Salmon," a pencil sketch of Mr. MCCULLOCH, and one of Master ALEC MCCULLOCH. Mr. SOLOMON has tempted the collector by only one work, and that of the year 1901, "The Judgment of Paris," beautiful, but hardly his best. The well-known—from engravings—"A Gambler's Wife" is the only example of Mr. MARCUS STONE. Mr. SWAN'S two paintings are "Orpheus" and the pastel, "A Tiger Drinking." Mr. WATERHOUSE is represented by "Saint Cecilia," "Flora and the Zephyrs," and "Ophelia"; Sir ERNEST WATERLOW by "The Orphan" and "Autumn Glory"; Mr. WOODS by "The Christening," "The Flower-seller—Venice," and "Good Afternoon," all Italian scenes; whilst Mr. W. L. WYLLIE is seen in a good example of his work, "Toil and Grime on a Flowing Tide."

From the elect to the stranger without the gates. "Valparaiso," one of the best of WHISTLER'S nocturnes, and his portrait, painted by himself, on the walls of the Royal Academy.

"The Garden of the Hesperides" and "The Daphnephoria" of Lord LEIGHTON in the same collection as

Digitized by Google

WHISTLER'S "Valparaiso" are surely sufficient to prove the truth of our assertion of the catholicity of taste and patronage dominant in the collector.

Many other pictures we should like to notice as those we enjoy—Mr. HENRY MOORE'S blue sea and "Breezy Day"; Mr. ALFRED EAST'S "Angry Dawn"; MICHAEL MUNKACSY'S "Tête-à-tête"; Mr. NAPIER HEMY'S "The Crew" and "Bass-fishing"; Mr. BRETT'S "The Grey of the Morning"; Mr. ORPEN'S "The Mirror"; FRITZ THAULOW'S "A River in Winter, with Trees," and many others.

One must not forget to mention that examples of BURNE-JONES'S work are in the collection; of BASTIEN-LEPAGE, of BOUGUEREAU, of GEROME, and of nearly all British painters that one admires, so that here is a unique opportunity for seeing some of the best of modern painting, collected with wide impartiality, but with wise discrimination.

STEELWORK.

By C. V. CHILDS, A.M.I.C.E.

[In the final sentence of the article that appeared in our last week's issue, reference is made to ferro-concrete construction; the following should have appeared as a footnote, but it had to be held over owing to want of space until this week.]

IT is the intention of the writer to deal with the subject of ferro-concrete in a few articles subsequent to those on steel construction; but in view of the fact that, before these may be published, new regulations may be drafted for the proposed new London Building Act, it is as well to draw attention to some facts in relation to this system of construction, which apparently have been overlooked, or perhaps glossed over by those who proclaim it the ideal method of construction applicable to structures of every sort and under all conditions.

Ferro-concrete has its own proper sphere in constructional work; but one may almost say that the craze for this class of work is causing it to be used under conditions which constitute it a serious danger, not so much at the present time, but in the not very distant future.

It seems extraordinary that the weak point in this construction has been overlooked, and it would be to the benefit of constructional firms, who make ferro-concrete a speciality, if they recognised the limits within which it is safe to use this form of construction; otherwise it may, before long, become discredited altogether, simply for this reason: a few bad failures might drive it away from its own legitimate sphere.

The weak point in ferro-concrete lies in the fact that the claim put forward as one of the chief reasons for its use is false.

This claim is, that the steel being embedded in the concrete, is protected from corrosion; true enough if the premises be correct; but this is not so in the case of ferro-concrete beams carrying even comparatively light loads, when exposed to the weather.

The usual allowable safe stress specified in ferro-concrete work is about seven tons per square inch for the steel tension bars. Within its elastic limit (for ordinary steel this is usually about fifteen tons per square inch, though for specially made steel this may run considerably higher) the strain is proportional to the stress; the strain being the amount the steel bar stretches. Without becoming too technical, it may be accepted that for a stress of seven tons per square inch this strain or elongation will be one 140th of an inch for every foot in length of bar stressed up to seven tons per square inch, and it is impossible to get the bar to take up the stress without developing the elongation. In other words this stress produces a strain of one 1,700th of the length of the steel bar.

It is seldom that concrete will stretch under tensional stress more than one 10,000th of its length. Converting this back into the steel bar it means that when the concrete has reached this limit and cracks appear, the bar in stretching one 10,000th of its length is stressed only up to one and one-fifth tons per square inch. The dead weight alone of the ferro-concrete beam may cause this amount of stress in this steel bar.

In actual tests, carried out on ferro-concrete beams, there is a distinct point where, after a small amount of loading is applied, the concrete, so to speak, lets go, and the steel takes up the tension, as is evidenced by a sudden slight deflection; this is undoubtedly due to the steel stretching slightly, when, instead of the concrete resisting the tension, this work is thrown suddenly on to the steel bars. These being more ductile than the concrete, they therefore elongate slightly more before adapting themselves to resist the tension. The case then stands that, when the loading produces a stress equal to about 1½ tons per square inch, the concrete has developed cracks, and the supposition is that the slight amount of elongation it was capable of has vanished; the under surface returns to its original length plus the width of the minute cracks; the concrete that was previously in tension now acts the part of the vertical struts in a king or queen post truss.

Presuming the load for which the girder is designed is applied and the stress in the steel bars becomes 7 tons per square inch, and presuming one crack opens in a two-foot length of the beam, the width of this crack would be $\frac{1}{70}$th of an inch at the distance up from the bottom of the beam where the steel is located.

Only a hair crack, it may be said, but so much the worse on this account, and all the more liable to contain moisture by capillary attraction, where the beam is exposed to the weather; it is also quite enough to expose the steel to oxidisation from either moisture or injurious fumes.

This then places the limit on ferro-concrete construction for beams. It essentially needs indoor protection and is in its proper sphere for filling in for floors, between main girders, and for that class of work.

For external work, unless some method can be devised by employing in its construction material in which the elongation can take place without exposing the steel, its use is distinctly dangerous; it may be, in a few years' time, when the small steel bars have become corroded, that failures will occur in ferro-concrete beams, especially those in exposed positions, where, as is usually the case, no further protection is afforded the steel than the concrete.

A drawback in ferro-concrete is that its most important element—namely, the steel—is buried out of sight and it is impossible to inspect the real condition of the beams; the steel is in bars or rods of small cross sectional area, and therefore more easily destroyed by corrosion than the larger areas used in the flanges of constructional steelwork. Yet how important it is for work of this description to be open to inspection at any time, when used in positions that expose the steel to corrosive agents; one has only to remember the scare that was occasioned a few years ago by the discovery of the dangerous condition of some of the girders over the Underground Railway. And yet the ferro-concrete enthusiast might probably advise the use of this construction in places such as these, claiming that the steel is so embedded and protected by the concrete that it is therefore indestructible.

(To be continued.)

ROYAL ACADEMY LECTURES—PAINTING.

THE second lecture of the course to be delivered in the lecture-room of the Royal Academy by Sir Hubert von Herkomer dealt with "Portraiture." He said that the practical side of his subject would be dealt with by him next year if he were alive. Portrait painting was the most human of all the arts, and might claim to be the most satisfying. It became history painting in the truest sense, for to paint man was to represent the world in its history. It was the most popular, the most indispensable and the most difficult of all the arts. From time immemorial man has tried to practise it. Man had ever been most interesting to man. In the early days the artist gave him the attributes of the beast. In spite of religion forbidding the exact representation of the human form, the idea was always there in Christian times. One may say that man is not a mere adjunct to the world—he is the world.

There will ever be those who deny the foremost position to portrait painting. But what is genre painting but portraiture? It is based on portraiture. Artists will always hold divergent opinions on the relative merits of their arts. We have portraiture in subject painting and subject painting in portraiture. This combination is seen in Millais's *The North-West Passage*. It is evident that the old man is visualising that passage as the young girl sitting at his feet reads without emotion. The frailty of the girl is emphasised by her robe, and makes a contrast with the rugged strength of the sea-dog. His calling is made obvious by the surroundings. She acts as a foil as she sits giving womanly consolation.

Historical painting is usually considered to mean the representation of scenes and incidents of which the painter

Digitized by Google

was not a witness. Portraiture is the basis in all the arts in which the human figure appears. In portraiture the personality of the sitter is everything. His character and temperament must be brought out in such a way that his friends will say "That is the man." Portraiture had to be first of all convincing—that is, it should be an artistic representation of nature. The truest portrait painter does not merely copy what is before him, he takes only such as is necessary to emphasise the character of the sitter. Yet the painter who accepts a commission for a portrait must give a satisfying likeness if he does what he is paid for. It is also true that the art he puts into his work cannot be paid for. In the career of Sir Joshua Reynolds many portraits were returned to him as unsatisfactory likenesses. Obtaining a likeness of the sitter was what made portrait painting most exacting. It has since become more acute than ever before owing to photography. Every urchin was familiar with the features of celebrities—statesmen, churchmen, actors, professionals of all kinds and music-hall ladies. Painters were apt to look slightingly on the faculty of likeness. But unless a portrait painter possessed it, he could never hope to be successful. In the case of an unsatisfactory likeness the artist says in defence, "That is what I see." But that will avail him little. He must either resort to bluff or return the fee. When a person on being shown a portrait said "It is a fine work of art," the artist could be certain there was something wrong with the likeness. Many painters failed because they did not study the character of the sitter before meeting him as a model. The likeness must be manifest in attitude as well as in face.

That portraiture enters into subject painting is suggested, in the first instance, by the fact that it is very usual for an artist to think of a subject after he has found a good model. That proceeding was hardly likely to lead to monumental art. Millais did not bother much about the subject when he had discovered a pretty model. Of many of his pictures it could be said that they are neither subject paintings nor portraits. Put briefly, the more they are portraits the less they are subject paintings, and *vice versâ*.

In painting the subject grows and enlarges if the original idea is a good one. Suppose a genre painter has found a couple of models for an Irish man and girl, and is uncertain how to use them. He is anxious to avoid repeating a worn-out love scene. Happy thought! Make it a gusty day, with Pat trying to light his pipe under a colleen's cloak. How is the spectator to know that he is using his last match? Happy thought! The title can tell him that. To add further importance to that last match introduce a pig (whose string Pat is still holding), trying to pull him away from the shelter of the cloak. Nobody would think that the pig was an afterthought. All this is genre portraiture.

True portraiture must start on a physiological basis representing the character and not the characteristics. A great portrait must speak. It should be not only a likeness, but a living likeness too. Though, paradoxical as it might sound, a portrait might be lifelike and yet fail as a likeness, it might be an excellent likeness and yet not be lifelike. It may be neither and yet be a very fine work of art. The greatest portraits have possessed the essential quality of repose which makes them monumental. Restlessness in a picture becomes disquieting—a twisted head induces a crick in one's neck. It is the result of a desire to surprise instead of charm. Merely to make a portrait recognisable is not enough to satisfy the demands of true portraiture.

The pictorial treatment of a man or a woman has probably had its last day. The evolution of portraiture as we know it through the centuries would be a most interesting subject. For instance, who first introduced behind the sitter a curtain hanging from nowhere, the landscape coming into the room, the staircase, the column and the various other devices we meet with over and over again? None of these probably came spontaneously, but they had become a convention. In many genre pictures there are absurd effects introduced in the backgrounds.

There was another convention that had come down to us. Supposing in a genre picture the sole figure is a man by a fireside, the light of which alone illuminates the room. It will be often found that on the canvas the side of the face away from the light is lighted up, showing that the work has been painted in the cold north light. The most illogical effects have been introduced in the greatest pictures. If they looked at Titian's great equestrian portrait of Charles V. in armour they would see that the dark side of his face is against a lurid sunset sky. Yet pictorially this illogical effect was stupendous. A background could make or mar a portrait. All he had said led to one thought—that a really good portrait is a wonderful thing. It is no small boon to mankind to have death robbed of much of its annihilating reality by the hand of the artist.

Sir H. von Herkomer took as the subject for his third lecture "The Philistine." He said that when he commenced writing it he did so with an open mind, not feeling quite sure on ,which side his sympathies would fall. The Philistine was a much maligned creature. The designation had been always most loosely used in this country without inquiry as to its meaning, and it illustrated the ease with which a corruption has set in. He himself had consulted encyclopædias and dictionaries without success. But by a fortunate circumstance he was now able to give the date and history of its original use, thanks to the help of a Professor at the University of Jena, whom he had met while painting in Devonshire, and to whom he had mentioned his difficulty. Early in the eighteenth century the students at that University distinguished themselves from the non-students in Jena by labelling them "Philistines"; the exact date of its earliest employment was 1693. Frequent serious quarrels took place between the two parties, for though the students mixed freely with the townspeople in the taverns (especially in those where dancing took place), once they were outside in the street no student would be seen with a townsman. In one of these conflicts the townspeople arrived in overwhelming numbers and routed the students, one of them being killed. The text chosen by the preacher for the funeral oration was "The Philistine is upon you." From that moment it signified the lesser minds or the middle line of intelligence.

Sir Hubert said that he wished to remove the quality of opprobrium which had been attached to the word in this country, where it represents the parochial intellect, the bourgeoisie. There must always be the low people, the middle and the high people. The middle people are bound hand and foot by their own morality, and somewhat despised respectability, which consists in avoiding the too little and the too much. Most curiously it was the artist who always uses the word Philistine as a term of opprobrium, though not very discriminately. An artist, after showing a visitor round his studio, mutters between his teeth "Philistine" as the man leaves without making an offer for a single picture. Should the same visitor come again next week and buy a canvas, the artist says, with a happy smile, "Good chap, after all!" Having weighed his qualities, he himself was prepared to say, "Bless the Philistine." What would the world have been without him? From time immemorial he has held the balance between sense and nonsense. According to his lights he has patronised the arts. Surely he is a man to be reckoned with. Moreover, he is a staunch friend, a right good fellow, a clear-headed counsellor. He sees the ground on which he stands, and rarely stumbles, though indeed he may keep on the dead level. Everything in his life is regulated by simple and conventional rules. Sir Hubert said he liked that man, he was glad to spend an evening with him occasionally. The Philistine is a good listener, being of an open mind, though it might remain open. The only complaint was that he will not have his portrait painted, arguing that he had no wish to eat his dinner in front of his likeness, an ungrateful nation would not buy it, and that he had better ways of spending his money.

The Philistine strikes a balance in morals and modern life; he is the middle line of intelligence from which we judge that which is above and that which is below. Philistinism should never be confounded with Puritanism—i.e. Puritanism as bearing on art and not on religion. In no European country has art felt the baneful influence of Puritanism as in England. The noblest forms of art represented the human figure, and flesh-painting was the highest achievement of the painter. If a man produced a work of art of that kind there was no need to inquire as to the means by which it was evolved, or as to the models. But the Puritan could not differentiate between the nude for art's sake and nakedness for immorality's sake. Of course there were abnormalities in that class of picture which sprung from diseased minds. Some years ago he sent to the Royal Academy a nude female figure with a sylvan background which he called "All Beautiful in Naked Purity." The hanging committee told him that because of English susceptibilities they did not dare hang it in the room it deserved. The gallery where it was placed was deserted (though its sole offence was that the figure was merely clothed in nature's garment), the seats knew no occupants, visitors rushed through casting a furtive glance at that picture. At last a Philistine boldly planted himself in front of it, but he was

Digitized by Google

carried off (mutely protesting "What is the harm?") by his wife. Yet these people who are so exacting in modern art are not prepared to logically follow their ideas to the old masters, whose nudities are accepted without demur. His picture was bought by a gentleman in Berlin, who built it into a niche in his dining-room.

The Philistines make up the large majority, and it was to them the painter and the sculptor must look for substantial rewards. If the artist relied on the sale of his works for a livelihood he could not escape the introduction of trade into his art. Art for art's sake—that studio cant phrase—was a contradiction in terms, or at best a stimulus. It was a very open question whether the artist would reach a higher level if he did not have to work for money. Such a condition weakened rather than strengthened the artistic capacity. For fear of being misunderstood he (Sir Hubert) would say that if money was a necessity to the artist, purity was a far greater one. The artist must preserve a purity of purpose, he must let nothing degrade him, he must force his personality on the public. But he ought to be just towards that middle line of intelligence. Doubtless his audience had discovered that he himself was a rank Philistine. He was willing to admit that he felt like one every time he sat with his colleagues of the Royal Academy. He was convinced that there was a touch of the Philistine in every human being from the artist to the grocer, and from the statesman to the ploughman. The Philistine demands something more than mere vertuosity in paint, he requires a story in a figure picture, a likeness in a portrait.

A friend of his had once asked why artists were so sensitive as to what newspaper critics said concerning their works. It was useless to pretend that an artist's reputation was built up on the verdict of his fellow artists; that is not enough, for it is not they who buy pictures. There is, however, a curious divergence between the criticisms of the Press and the opinion of artists; the former rarely fail to reveal the puzzled condition of the writer's mind. But there was much to be taken into account before they condemned the art critic. His time is too short, many visits to an exhibition being necessary for a sound opinion instead of one of merely a few hours. Frequently the writer would, if he could, change his mind on a maturer consideration of his hasty impression. Moreover, the critic is not always an altogether free agent, being under his unsympathetic editor, who probably regards the space occupied by art criticisms as wasted. Their articles are sometimes so edited as to be unrecognisable. Some people say that a war is going on between art critics and editors.

Artists have often strong opinions, and are impatient of ideas that do not conform with their own. On one occasion Millais was walking with Sir Hubert through the Grosvenor Gallery, and in passing by a room containing pictures by Burne-Jones he waved his hand and remarked, "Oh, I cannot understand that man."

Something must be done to check the ever growing indifference of the public of this country to art. Artists themselves were not altogether without blame in the matter. First, they ill-disguised their contempt for that middle line of intelligence on whom they depended for worldly reward; secondly, they offered work that often outraged taste; and lastly, they expected to be judged differently in art and conduct from the rest of mankind. The artist should in every way strike a note of probity. It is no compliment to say that he should be judged by a standard different to that of the rest of mankind. No one has benefited by the absence of sober judgment in his work or life. A little exaggeration both in their admiration and condemnation, and a little less impatience with all opinions that differed from their own, was a consummation devoutly to be wished.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

Messrs. W. G. Newton, W. J. Price and M. F. Surveyor were elected members.

On the motion of the PRESIDENT, votes of condolence were passed to the widow and family of the late Mr. W. M. Fawcett and the family of the late Mr. E. A. Gruning.

The PRESIDENT announced that Mr. J. H. Markham would read a paper at the next meeting, January 22, on "Reinforced Concrete," Mr. Buckland's paper, dealing with "Schools" and originally fixed for that date, being postponed until February 5.

Mr. H. D. SEARLES-WOOD read the following paper, entitled—

Materials.

Some interesting results as to the relative strength of concrete made with aggregates of broken brick and gravel respectively, and also with broken brick and gravel mixed in varying proportions, have been obtained from experiments instituted by H.M. War Department in connection with the construction of a large building, for which it was calculated that a maximum weight of two tons per foot super would be brought upon the concrete foundations.

The experiments were carried out by means of cubes of concrete 1 foot by 1 foot by 1 foot, mixed and put together under precisely the same conditions as occur in actual practice. The aggregate of broken brick or gravel was broken to 1½-inch gauge and mixed with a sufficient proportion of sand to fill the interstices. Briquettes of the Portland cement used for making the concrete were previously tested, and successfully withstood a tensile strain of 400 lb. per square inch of section after seven days' immersion in water. Four blocks of each of the following varieties of concrete were then made, viz.:—

1. Concrete composed of six parts cleaned broken brick, one part sand and one part Portland cement.
2. Concrete composed of six parts uncleaned broken brick, one part sand and one part Portland cement.
3. Concrete composed of six parts broken stone, one part sand and one part Portland cement.
4. Concrete composed of three parts of cleaned broken brick, three parts broken stone, one part sand and one part Portland cement.
5. Concrete composed of four parts cleaned broken brick, two parts broken stone, one part sand and one part Portland cement.

The bricks used for the aggregate were very old, rather soft and easily broken, having pieces of the old mortar adhering to their surfaces; in the remaining instances the old materials were roughly cleaned from mortar before breaking to the required gauge. The concrete blocks were forwarded to Messrs. Kirkaldy & Sons, and their actual resistance to compression ascertained after being allowed to set in air for thirty-one days. Each block was bedded between pieces of yellow pine, ⅜ inch thick, before being tested.

DIAGRAM I.—*Strength of Portland Cement Concrete Blocks to Resist Compression after being Allowed to Set in Air for Thirty-one Days.*

No.	Description of Concrete.	Weight lb. per cube foot.	Slightly Crushed. Tons per square foot.		Crushed. Tons per square foot.	
A^1	6 parts cleaned broken brick, 1 part sand, 1 part cement	123	22·6		24·4	
A^2	Do. do.	115	17·9	17·1	20·1	20·0
A^3	Do. do.	124	12·0		18·1	
A^4	Do. do.	119	15·9		17·3	
B^1	6 parts uncleaned broken brick, 1 part sand, 1 part cement	124	20·3		21·3	
B^2	Do. do.	123	17·2	16·8	18·3	18·6
B^3	Do. do.	119	15·0		18·1	
B^4	Do. do.	118	14·7		16·7	
C^1	6 parts broken stone, 1 part mud, 1 part cement	137	15·6		17·1	
C^2	Do. do.	138	13·4	12·3	15·0	14·1
C^3	Do. do.	141	13·4		14·4	
C^4	Do. do.	139	6·7		10·0	
D^1	3 parts cleaned broken brick, 3 parts broken stone, 1 part mud, 1 part cement	128	18·1		19·4	
D^2	Do. do.	126	15·4	15·4	16·4	16·6
D^3	Do. do.	128	15·4		16·3	
D^4	Do. do.	126	12·9		14·1	
E^1	4 parts cleaned broken brick, 2 parts broken stone, 1 part mud, 1 part cement	124	14·3		16·3	
E^2	Do. do.	124	12·6	12·4	16·0	15·2
E^3	Do. do.	1 6	13 7		15·4	
E^4	Do. do.	128	9·1		13·3	

The terms "sand" and "gravel" are a trifle indefinite, so for the sake of distinction all mixtures that will pass a sieve with a ¼-inch mesh is sand, and all that will not pass is gravel. Good authorities state that loose gravel of ¾-inch diameter and under contains about 33⅓ per cent. of voids, which is reduced to 21 per cent. by ramming. From this it can be seen that one part of sand will fill the voids in three parts of gravel; that is a mixture of 1 to 3 The percentage of voids increases somewhat with an increase in the size of the gravel, which would correspondingly decrease the above ratio. The gravel should be of different sizes, varying from coarse to fine screened or washed entirely free from clay, loam or other foreign matter, and be free from scale, slime or humus.

Digitized by Google

Gravel sufficiently clean can often be obtained from river beds or gravel pits, but rarely from gravel banks. Gravel can be readily cleaned by sluicing. Sufficient water should be used to carry away all objectionable matter, including fine sand. As a rule, more cement is required in gravel concrete than in the same volume where broken stone is used; 10 per cent. is about the amount of extra cement that should be used in gravel concrete over and above that required with broken stone.

If the building is on a clay subsoil an excellent substitute for the layer of cement concrete over the site of a domestic building can be made by burning the clay and mixing the burnt ballast with gas tar whilst it is hot; the mixture can be left for some time till the brick footings are laid, and then it is spread over the site and well rammed, and it will be found to be more impervious than the cement concrete.

With the introduction of reinforced concrete building much greater attention has been paid to the methods of testing Portland cement and selecting the materials for the aggregate.

The following is from a report of the materials sub-committee of the reinforced concrete committee of the Royal Institute of British Architects:—

Cement.—Only Portland cement complying with the requirements of the specifications adopted by the British Engineering Standard Committee should be employed; in general, the slow-setting quality should be used. Reasons for this recommendation:—The exclusion of concrete made with lime or natural cement appears desirable, not only because the term "reinforced concrete" is now generally applied to work in which only Portland cement concrete is used, but because the presence of unslacked particles of lime and the uncertain results obtained from limes and natural cements constitute an element of danger. Moreover, the lower resistance of the resulting concrete prevents the full strength of the reinforcement being utilised.

The slow-setting quality is desirable, in that a certain time must always be required in putting the concrete in position and thoroughly ramming it, and a quick-setting cement might set before these operations were completed, to the danger of the work.

The cement should be delivered on the works in bags or barrels bearing the maker's name and the weight of the cement contained.

Every lot of cement delivered should be tested to make sure that it complies with the requirements of the standard specification before it is used. These tests may be made at the maker's works or elsewhere. In addition, the tests for soundness and time of setting, which can be made without expensive apparatus, should be applied frequently and all cement rejected which fails to pass the tests. These tests are:—(1) Gauge a small portion of the neat cement into a plastic mass with from one-fifth to one-fourth its weight of water, place this on a small piece of glass, slate or enamelled tile (not porous) and allow same to set out of contact with the sun, draught or vibration and in a damp atmosphere—say, under a damp sack, so that the sack does not touch the cement. After the expiration of twenty-four hours place the set pat in a saucepan (preferably enamelled) with cold water, and bring same slowly to a temperature a little below boiling and keep at same for about three hours. If the pat remains sound or shows only slight hair cracks, the cement may be safely used immediately. The setting time may also be noted by pressure of thumb nail on similarly gauged protected pats, when it will be easily seen whether the cement is a quick-setting or slow-setting one, in accordance with what is required. The cement may be considered set when hard pressure with the thumb nail only makes a slight impression.

Sand.—The sand should be composed of grains of various sizes up to particles which will pass a ¼-inch mesh. Fine sand alone is not suitable. It should be clean and free from core, ligneous, organic or earthy matter. The value of a sand cannot always be judged from its appearance, and tests of the mortar prepared with the cement and the sand proposed should always be made. Washing sand does not always improve it, as the finer particles which may be of great value to the compactness and solidity of the mortar are carried away in the process. Sand which looks impure is not always unserviceable. It appears that freely divided particles of clay or loam which do not adhere to the grains of sand may improve the resulting mortar. It is, however, difficult to fix upon the actual amount of impurity which may be allowed, and the word "clean" is retained, calling attention to the fact that a certain degree of impurity is not prejudicial. The word "sharp" usually employed in the description of sand has been omitted, as it appears that the angularity of the grain which gives the quality of sharpness is of very little importance compared to the size and variation in size.

Gravel or Hard Stone.—The gravel or hard stone should be clean and angular, varied in size as much as possible between the limits of size allowed for the work. In all cases material which passes a sieve of a ¼-inch mesh should be excluded or reckoned as sand. The maximum allowable size is usually ¾ inch, which should be reduced to ½ inch or less in thin floors or in columns. The maximum limit must always be such that the gravel or broken stone can pass between the reinforcing bars and between these and the centring.

The sand should be separated from the gravel or broken stone by screening. It was thought desirable to confine the recommendations at present to the use of gravel or hard, broken stone, as concretes of cinder, coke-breeze, slag, or soft stone are of much lower strength, and are comparatively little used in reinforced work.

The material to be used must, of course, be fixed in relation to the stresses allowed upon the material. As it is very necessary to have correct proportions for all the materials it is advisable to screen the gravel.

The amount of cement to be added to the aggregate should be specified by weight. The weight of a cubic foot of cement for the purpose of proportioning may be taken at 90 lbs.

The amount of cement in a cubic foot varies much with the method of filling and the size of the vessel used and the size of the volume used. The French standard measure is a litre, and the method of filling is through a conical riller having a sieve in the middle of it, and of which cone the nozzle is about 2 inches above the litre measure. Determined by this method, the weight of cement is usually under 1,100 grammes per litre, which is equivalent to 68.64 lbs. per cubic foot, and there is little variation in repeated trials of the same cement.

If a larger measure than a litre is used, there is not only a greater weight per volume, but a greater variation in different weighings of the same cement in the litre measure; about 3 per cent. variation may be expected in a 50 litre measure; there might be as much as 13 per cent. even when carefully filled in by a standardised method.

In fixing the proportion betwen volume and weight the committee had also to consider what had been generally understood by the expression "one of cement to one of sand." It appears that a 200 lb. bag of cement has been hitherto generally considered as the equivalent of rather more than 2 cubic feet, and that proportions are generally determined on the basis of 90 lb. per cubic foot. The German Engineers' and Architects' Association recommend that for mixtures by weight, 1,400 kilos should be taken as the specific weight of the cement. This is equivalent to 86.36 lb. per cubic foot. The sand and ballast are also sometimes determined by weight. It is found that sand weighs from 85 lb. to 117 lb. per cubic foot, and the contents of a vessel containing a cubic foot of cement varies between the same figures according to the manner of filling. The adoption of so small a measure as a litre, though giving a more accurate comparison between the weights of two cements, would make the equivalent mixture much leaner than has hitherto been understood.

The exact determination of the ratio between weight and volume does not appear of so much importance for proportioning as general agreement upon the meaning of such expressions as "one of cement to two of sand and four of gravel." The committee therefore recommend that the cubic foot be taken as weighing 90 lb.

The proportion of sand to be added to the cement should be specified independently of the gravel, broken stone or other aggregate. In general the volume of the aggregate should be double the volume of the sand. There are two or three methods of doing this. The American practice appears to be to give the proportion of cement, sand, and aggregate between colons—1:2:4 or 1:3:6. On the Continent of Europe it appears usual to specify weight of cement in kilos.: cubic metres sand: cubic metres aggregate, also between colons.

The metal used should be steel having the following qualities:—

(*a*) An ultimate strength of not less than 60,000 lb. per square inch.

(*b*) An elastic limit of not less than one-half the ultimate.

(*c*) An elongation of not less than 22 per cent. in the lengths stated below.

Digitized by Google

(*d*) Standing bending cold, 180 degrees to a diameter of the thickness of pieces tested without fracture on outside of bent portion.

Test pieces should be planed or turned before being tested except in the case of rounds less than ½ inch diameter.

The elongation should be measured on a length of 8 inches, except in the case of sections less than ⅝ inch diameter, in which case the elongation should be measured in a length equal to eight times the diameter.

Before use the metal ought to be clean and free from scale or loose rust. It should not be oiled or painted, and a wash of Portland cement grout is desirable. Welding should in general be forbidden. If it is found necessary, the welding should be at points where the metal is least stressed, and it should never be allowed without the special sanction of the architect or engineer responsible for the design.

The requirements for the metal are those usual for mild steel, save that there is no upper limit of ultimate strength. This upper limit has been expressly included in order that a harder steel may be used when thought desirable, provided only that the elastic limit is correspondingly raised. It is the elastic limit which is the important one, as reinforced concrete beams usually fail when the stress in the steel slightly exceeds that limit. In cases where rods are too long to be in one length, it appears desirable to hook them or to overlap and bind them with wire.

In all cases the concrete should be mixed in small batches in accurate proportions on large, boarded platforms. The bag of cement containing a fixed weight forms a convenient unit, and gauge boxes of a size to contain the proportionate quantity of sand and gravel or broken stone to be added to the weight of cement contained in the bag should be used.

If one box is used to contain the proper quantity of sand and gravel or stone it may be divided by a mark on the box into two unequal parts, the lower part for the sand, which should be filled in first, and the upper part for the stone or gravel, which should be first wetted. When the materials are mixed by hand they are to be turned over and thoroughly mixed by shovels and rakes with long prongs until the colour of the cement is uniformly distributed over the aggregate. Sufficient water should then be added to ensure that when a ball of the concrete is made and pressed together in the hands the water comes to the surface. The reason for the concrete being mixed in small batches is that it can be used at once on the work; when concrete is made in large batches some of it is almost certain to begin to set before it is used. Before the work is begun, and during progress test, pieces should be made of the cement, sand, and aggregate to be used in the work mixed in the proportions specified. These pieces should be either cubes of not less than 4 inches each way, or cylinders not less than 4 inches diameter, and of a length not less than the diameter. They should be prepared in iron or hardwood moulds and firmly punned with iron beaters. Not less than four cubes or cylinders should be used for each test, which should be tested by comparison in a proper machine, the load being slowly applied. The average of the results should be taken as the strength and should not be less than 2,500 lb. per square inch. Loading tests on the structure itself should not be made until at least two months have elapsed since the completion of the work. The test load should not exceed one and a half times the accidental load. Consideration must be given to the action of the adjoining parts of the structure in cases of partial loading. Tests of too severe a kind are calculated to permanently injure the structure, and are not desirable. Cracks may be more easily detected if the surface of the concrete is wetted, and this may be done while the load is on.

Up to a few years ago, the general opinion was that the addition of sand to calcined fat lime (although primarily added as a deterrent and to prevent shrinkage) had a chemical function, causing the formation of a hard silicate of lime. At the present time the opinion is that the setting of mortar made with pure fat lime and sand (or broken brick or similar material) is solely due to the drying of the lime and to the formation of carbonate of lime with the carbon dioxide in the atmosphere, and that no chemical action occurred between the sand and lime. The presence of powdered brick or sand merely allows of a greater number of air passages in the mortar, thereby facilitating the drying action and carbonising action of the atmosphere. The particles of lime also adhere more readily perhaps to the sharp fragments of brick or sand than they would to one another. In other words, the action of sand and similar substances on lime is purely physical, not chemical. If, however, the calcined lime is mixed in the presence of water not with sand, but with silica in an "active" form, i.e., amorphous, and generally hydrated or with a natural silicate which contains silica in an active condition, then it will unite with the silica and form a silicate of lime capable of withstanding the action of water to a certain degree. This resulting substance is called a pozzuolanic cement, and the great difference between a pozzuolanic cement and a Portland cement is that in the former the silicate of lime is formed after burning the lime by the addition of active silica, and in the latter the silicate of lime (and aluminate of lime) are formed during the burning of the lime at an extremely high temperature. There are several substances occurring abundantly in nature, mostly of volcanic origin, which contain active silica, such as pumice, tufa, trass and pozzuolana, which last, for instance, contains about 60 per cent. of silica, over one-half of which is soluble or active silica capable of directly combining with the lime on the addition of water. River sand is largely used on the Continent for making mortar. Experiments have been made with ½ trass, ½ cement, 3 sand, which gave a breaking weight of 333⅓ lb. per square inch at six months and 343½ lb. at twelve months; while the same cement mixed 1 cement, 3 sand, gave only 265⅔ lb. at six months and 230 lb. at twelve months. Seven trass, 1 cement, 3 sand, 7 gravel failed at 3,000 lb. per square inch, the same cement mixed 1 cement, 3 sand, 6 gravel failed at 2,000 lb., both were tested at 100 days.

Pumice gravel is used as an aggregate for concrete when lightness is required, the average crushing stress it stands is 536.63 lb. per square inch; the specific gravity of this concrete was found to be .49 when dry, and 1.24 after twenty hours' immersion in water.

(*To be concluded.*)

An Exhibition is to be held, under the patronage of Queen Alexandra, at the Tuileries in May and June next, of 100 English and French portraits of women of the eighteenth century. A representative French committee has been formed to select the portraits of the French school, and an English selection committee for the British school has been appointed, under the chairmanship of the Earl of Plymouth, consisting of the following gentlemen:—Sir Walter Armstrong, Mr. Lionel Cust, Mr. A. G. Temple (honorary secretary), Mr. Claude Phillips, Mr. Sidney Colvin, Mr. Roger Fry and Mr. Herbert F. Cook. Some of the greatest works of Boucher, Nattier, Van Loo, Largilliere and others will appear in the French section, while in the English Reynolds, Gainsborough, Romney, Hogarth, Raeburn, Hoppner will be seen. The total value will be one million sterling. The profits of the exhibition are to be devoted entirely to the Society for the Aid of Widows and Orphans of French Naval Officers and Seamen.

In the Report of the progress and work of the Society of Antiquaries of Scotland during the year it is stated that, commencing the year with a membership of 704, the Society had lost by deaths and other causes forty-two members, but the number of new members added had been forty-five, so that they began the new year with a membership of 707. The excavation of the Roman fort at Newstead, begun in 1905 under the supervision of Mr. James Curle, Melrose, had been continuously carried on during this year with satisfactory results, as would be seen in the very remarkable collection of relics from it, now numbering over 2,000, which were exhibited in the museum. Inclusive of these the museum had received additions during the year of 1,430 objects by donation and seventy-three by purchase, while the library had been increased by 165 volumes by donation and fifty-two by purchase. The most important of the donations received during the year was presented by the representatives of the late Sir Francis Tress Barry, Bart., consisting of about 1,400 objects, chiefly obtained during his extensive excavations of the brochs on his estate of Keiss, in Caithness, and in the surrounding neighbourhood.

The Education Committee of the Heriot Trust, Edinburgh, have resolved to grant facilities to the provincial committee for the training of teachers for the practical training in teaching in George Heriot's school of students of the Edinburgh College of Art who desire to obtain recognition as art teachers. Mr. Campbell Mitchell, superintendent of the evening classes at the College of Art, has been recognised by the Scotch education department as master of method to supervise the training. The provincial committee will make to the governors a payment of 10*s.* per student as a fee for the teachers of the art department for their trouble.

NOTES AND THE WEEK.

IT is, we think, little known to architectural students generally that among the British Institution Scholarships is one for architecture of 50*l.* a year, tenable for two years, candidates for which must be not more than twenty-five years of age, and must have obtained a gold medal or a scholarship or money prize of the minimum value of 5*l.* in any art school in the United Kingdom. We take it that the Architectural Association, University and King's Colleges, London; Manchester, Liverpool, Leeds, and Sheffield Universities would be recognised as art schools for the purposes of these scholarships.

THE British Fire Prevention Committee has just issued three of its Red Books dealing with tests made on fire extinguishers. The first of these Red Books records the tests made by using plain water applied from vessels in common, everyday use—buckets containing about two gallons, bedroom pitchers, kitchen quart jugs, and kitchen tumblers, also an ordinary hand-pump such as is commonly used for garden purposes. These all proved effective when energetically applied in extinguishing small fires in their early stages, save in the case of petrol, even burning celluloid being mastered by plain water in twelve seconds.

THE second series of tests recorded were made with a 125-gallon high-pressure tank fire extinguisher of American manufacture, and demonstrated its efficiency in dealing with small fires either as operating sprinklers or as a supply for hose and nozzle. As the liquid ejected upon the fires was a plain water solution of bicarbonate of soda, impelled by and partly impregnated with carbon dioxide gas, it is scarcely surprising that it was unable to completely extinguish burning petrol, although successful against other varieties of small fires. The time limit of the efficiency of the tank is, of course, chiefly determined by the size of the particular tank.

THE third Red Book is an account of tests arranged in conjunction with the Incorporated Association of London Dyers and Cleaners, and was especially directed to the problem of dealing at an early stage with fires likely to occur on the premises of dyers and cleaners from the ignition of petrol. The value of asbestos cloths for smothering, checking and extinguishing burning petrol was conclusively proved. It was also shown that steam injected into a chamber containing blazing petrol extinguished the fire, provided the amount of steam was sufficient in comparison with the size of the chamber.

ILLUSTRATIONS.

HOLBORN TOWN HALL.—ADDITIONS—THE PRINCIPAL ENTRANCE—THE COUNCIL CHAMBER.

THIS building was erected in order to carry on the municipal work of the borough under one roof. In 1906 an architectural competition was instituted in order to obtain designs for the new offices, and from among the names submitted to them the Council selected six firms to compete, viz. Messrs. COLLCUTT & HAMP, HENRY T. HARE, E. T. HALL, Sir BRUMWELL THOMAS, G. C. HORSLEY, and Messrs. WARWICK & HALL. The designs of Messrs. WARWICK & HALL, of 13 South Square, Gray's Inn, W.C., were selected as being the most suitable to the requirements of the Council, and they were accordingly entrusted with the carrying out of the work. The foundation-stone of the new offices was laid on October 3, 1906, by the Mayor, Professor WILLIAM R. SMITH. The building was formally opened on October 13, 1908, by the Lord Mayor of London, Sir JOHN BELL. The work was carried out by Messrs. JOHN GREENWOOD, LTD., of London, during the mayoralties of Professor W. R. SMITH, 1906; Mr. W. DONALDSON RAWLINS, K.C., 1907; and Lieut.-Colonel LACY W. RIDGE, 1908, who were each chairmen of the building committee in turn. The building is erected at the junction of High Holborn and Broad Street, adjoining the Holborn Public Library, with which it forms one building when seen from the street. Although the library heights are followed in the elevations, the old offices of the Borough Council are retained intact in the new plan, and have been used by them throughout the execution of the work, without the necessity of their finding temporary office premises. Internally each floor has a large circular hall adjoining the main staircase, in which a passenger lift is provided to all floors. The council chamber, on the second floor, is in a quiet position, free from the noise of all traffic. A gallery for the public is provided, entered by a separate staircase from the street. On the same level as the council chamber are the committee rooms, members' rooms, mayor's parlour, and ante-room. Immediately under the council chamber is the Court-room, in which the magistrates will hear licensing and other business, and where rating assessments will be conducted. Inquiry and waiting rooms are planned close to the Court. The remainder of the building is occupied by the borough officials, whose departments are in each case self-contained. Service lifts for food and books are provided from the housekeeper's rooms on the fourth floor to the strong rooms in the basement, with a servery on each intermediate floor.

The sub-contractors were:—Constructional steelwork and fireproof floors, G. ASTON & SONS, LTD.; heating and ventilation, J. JEFFREYS & Co.; stone, the Ancaster Stone Co.; artificial stone staircases and granolithic paving, F. BRADFORD & Co.; marble and mosaic, DIESPEKER, LTD.; electric passenger lift and service lifts, R. WAYGOOD & Co., LTD.; wrought-iron lift enclosure, balcony and gates, the Bromsgrove Guild; electric lighting, FOOTE & MILNE, LTD.; stone and wood carving, panelling and seating in council chamber, H. H. MARTYN & Co., LTD.; fibrous plaster work, VERONESE, LTD.; metal casements and leaded lights, R. E. PEARSE & Co., LTD.; electric-light fittings, J. W. SINGER & SONS, LTD.; grates, BRATT, COLBRAN & Co.; door furniture, CARTER & AYNSLEY, LTD.; locks, CHARLES SMITH & SONS, LTD.; sanitary fittings, SHANKS & Co., LTD.; furnishing, THOMAS WALLIS & Co., LTD., and JAS. SHOOLBRED & Co.

EASBY, NORTHWOOD.—ENTRANCE VIEW—GARDEN VIEW.

THIS house was built a few years ago on a high and beautifully wooded site at Northwood. The external walls are of brick, covered with rough-cast and whitened, and the roof is of tiles. The ground floor has the following accommodation:—Hall with fireplace, dining-room and drawing-room (both leading on to the verandah of garden-front), study, lavatory, w.c., kitchen, pantry and the usual offices; also a two-stall stable and coach-house. The first floor has five bedrooms and a dressing-room, with bathroom, &c., whilst there are two large bedrooms and a boxroom in the attic. The internal and external joinery is mostly finished in white; but the main staircase is of oak, some old balusters having been incorporated in it. Mr. F. HILL, of Northwood, was the builder, and Mr. WALTER E. HEWITT, A.R.I.B.A., of 22 Buckingham Street, Strand, W.C., the architect.

LIVING ARCHITECTS.—NO. 2, MR. T. G. JACKSON, R.A.

THIS week we give the second of our series of pen-and-ink drawings representing architects in practice in this country. The one shown last week was of Mr. ERNEST GEORGE, P.R.I.B.A. Our second represents Mr. T. G. JACKSON, R.A.

"ARCHITECTURE: ITS TRUE PRINCIPLES," by Mr. R. OWEN ALLSOP, of which we gave the introductory chapter in our issue of last week, will be resumed on January 22. The letterpress will be again accompanied by a number of text illustrations. Dr. HOLDSWORTH'S Articles on the Workmen's Compensation Act will also be resumed.

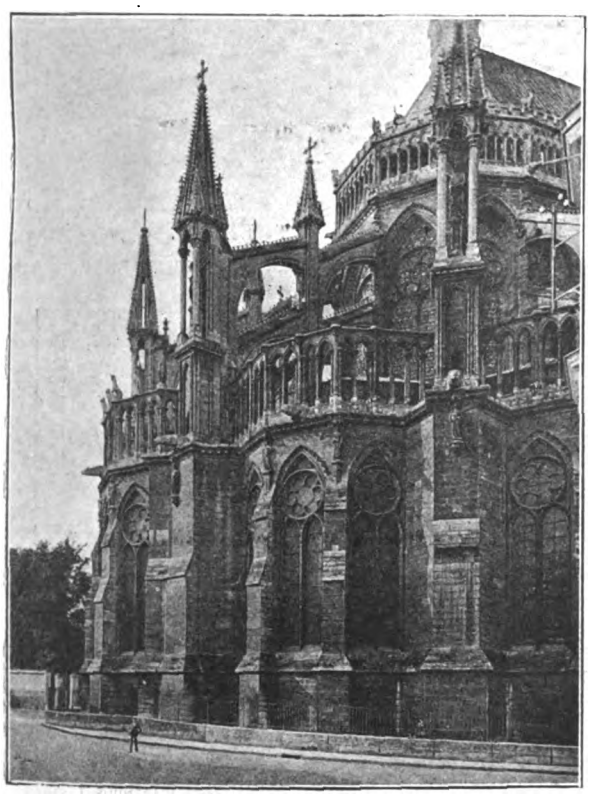
RHEIMS CATHEDRAL—THE CORONATION CHURCH OF FRANCE.

By Professor CHARLES GOURLAY, B.Sc., A.R.I.B.A.



(Concluded from last week.)

EXTERIOR OF APSE AND EASTERN CHAPEL.

PROFESSOR LETHABY has recently pointed out the remarkably close resemblance of certain parts and details of Rheims Cathedral to similarly situated parts of Westminster Abbey. He says:—"The most striking likeness in detail is that one type of window, consisting of two lights with a big rose above, combined into tracery, is used throughout both churches, in the aisles, around the chapels and along the clerestories." This window has fully-developed bar-tracery.

The exterior of the apse and eastern chapels is very richly treated. The large buttresses have angels with outspread wings sculptured on them, and they are terminated with pinnacles containing statues and richly decorated slender spirelets. Round the eaves of the roofs of the chapels there is a tall open arcading which takes the place of the parapet, while there is a similar arcade, blind in its upper part, round the eaves of the roof over the apse proper. Directly above the smaller buttresses angels again are sculptured, and they are very happily placed at the junction of the straight sides of the small apses to the chapels.

There were no later chapels added to the aisles of the nave at Rheims, as was done at Amiens and elsewhere;

RHEIMS CATHEDRAL.—APSE AND EASTERN CHAPEL.

hence, externally, the buttresses are seen in their true projection down to the ground line.

NORTH ELEVATION.

At the base of the rose window in the north transept there are large statues of ADAM and EVE, and in smaller figures in the arch-mould there are representations of the Creation, Fall, Murder of ABEL, and Invention of the First Trades. Above is a gallery of seven statues representing the Prophets. In the gable, which dates from the beginning of the sixteenth century, there is sculpture representing the Annunciation.

Over the crossing there formerly existed a high leaden flèche, but now there is a small belfry of seventeenth-century date enclosing a chime of thirteen bells. There formerly existed four spires at the ends of the transepts, but now these are roofed with low pyramidal roofs, the original spires, as also that over the crossing, having been destroyed by fire in 1481, which disaster absorbed the resources available at that time for the normal completion of the edifice. The very beautiful octagonal flèche which forms the crowning feature of the chevet is 13½ feet wide at the base and about 56 feet in height. It dates from about 1505. The cove at its springing from the roof is decorated with eight large statues which are of lead. This flèche was formerly terminated by the figure of an angel, made of copper, carrying a cross which acted as a vane as well as finial; hence the name given to this flèche is the *Clocher de l'Ange*. This figure, however, was taken down in 1860 and has never been replaced.

SOUTH ELEVATION.

At the base of the rose window in the south transept are the two well-known statues representing, to the west, the Church Catholic—the figure holds a chalice in her hand; to the east, the Synagogue—the figure in this case has a veil over her eyes. Around the rose window appear the Prophets and the Apostles. The seven statues in the gallery above represent the sacred Writers; these have small angels between their heads, cut in the solid tympana of the intermediate arches of the arcade, which forms a series of canopies over the heads of both statues and angels. The sculpture in the gable of this transept represents the Assumption, and dates from about 1506, while at the apex is a leaden figure representing SAGITTARIUS in the act of discharging an arrow to the court of the Archbishop's Palace below, where formerly was a bronze stag at which the arrow was directed.

PINNACLES AND BUTTRESSES.

The cathedral suffered from mutilations in the eighteenth and during the first half of the nineteenth centuries. Since the middle of the nineteenth century very important restorations have been effected at many parts and these are still being continued. The elaborate balustrading or parapet of open arcading at the eaves of the roof of the nave is a restoration. It is about fourteen feet high and has a very rich effect.

Referring to the fine effect of the great flying buttresses, FERGUSSON says truly:—"The beautiful range of buttresses which adorn the flanks of the building are perhaps the most beautiful in France, and carry the design of the façade back to the transepts."

INTERIOR, NAVE.

Standing in the interior at the crossing and looking westwards in the nave, the general effect is grand and, generally speaking, much simpler than the exterior. The proportions of each bay—the piers with the arcading, the triforium and clerestory—appear to be perfect, and with all this the quadripartite vaults are quite in harmony. The excellent proportions of the west central doorway, with its traceried tympanum and internal sculpture, lighted arcade above it, and large rose windows, are seen to advantage from this point, and it must be admitted that the combined effect is splendid. The lighted arcade below the rose window enables a comparison to be made with the dark arcade of the triforium, whereby the great advantage which a lighted triforium gives to an interior over that of a "blind" storey is strikingly apparent. The stained glass in the clerestory of the nave all belongs to the thirteenth century, and its effect is fine and rich. As, however, there is no stained glass in the aisle windows the lighting of this interior is not satisfactory, because the principal light in such a cathedral nave as this is should come from the clerestory and not from the aisles. If the aisles were even now to receive stained glass the main lighting would come from the clerestory and the effect would be delightful. The height of the inferior to the underside of the vaulting is nearly 125 feet.

INTERIOR, CHOIR.

Looking now to the eastwards the apse is seen to be divided into three storeys, not four, as is the case in the Abbey Church of St. Remi in the same city, and which, being an earlier edifice, must have influenced the design of the cathedral to some extent at least. The clerestory

is formed of windows, which are divided into two by a mullion and surmounted by a rose window which has a very large space above it. The triforium is dark and very simple in treatment. The five bays of the triforium in the apse each consist of two arches divided by a central pillar, in front of which the mullion of the window above passes down as a column, thus uniting the clerestory and triforium. Throughout the rest of the edifice there is no such binding feature between the two storeys. The wall behind the triforium has been painted a dark blue, which makes the small columns in front appear thicker than they really are.

The glass in the clerestory of the apse, which all dates from the middle of the thirteenth century, has a blue ground, and is admirable in its translucency, variety and richness. Owing to the presence of modern stained glass in the lower windows of the chevet chapels, there is not in the choir that unhappy effect of its being lighted from below which, as already stated, exists in the nave. The vault of the choir, including the crossing and all eastwards, is painted a dark blue ground with gold fleur-de-lis over it, arranged as a diaper pattern. The chapels of the chevet have nearly all been decorated in modern times. It is when looking eastwards in the interior that the striking resemblance of the interior of Westminster Abbey to that of Rheims Cathedral makes itself most strongly felt.

TAPESTRY.

In the nave and transept some valuable tapestries and several paintings are preserved. Most of the tapestry was presented by ROBERT DE LENONCOURT, Archbishop of Rheims, in 1573, but is of much earlier date. While this tapestry gives an interesting note of colour to the interior of the cathedral, nevertheless, as the pieces extend so as entirely to fill up each bay between the responds in the aisles, and are not hung so as to correspond in height with any horizontal member, they appear to give a discordant note to the interior—they certainly tend to spoil the proportions wherever they are seen in conjunction with the architecture.

CARVING.

The carvings of the capitals of the pillars of the nave are greatly varied, and are all based upon natural forms to a greater or less extent. That of the sixth pillar to the right, dating from the fourteenth century, has the celebrated "Capital representing the Vintage," which is undoubtedly one of the best works of its kind belonging to the Middle Ages. It is a particularly fine example of architectural foliage based upon natural forms. The vine is well and clearly portrayed, also the manner in which the grapes are gathered by the workers.

CONCLUSION.

The "Lamp of Beauty," as expressed in Rheims Cathedral, has been the subject of this article, but few of those who study this great mediæval monument from the point of view of the science displayed in its constructional design and compare it in this respect with other examples, such as Amiens Cathedral, will disagree with the well-expressed statement of EDOUARD CORROYER, in which he says:—"Rheims Cathedral may be taken as the most perfect manifestation of persistent efforts to establish a method of construction based on equilibrium—the equilibrium, that is to say, of a building vaulted on intersecting arches, the thrusts of which are received by exterior flying buttresses."

When it is recollected that the erection of this edifice occupied many years, it is well worth observing how the original design by JEAN D'ORBAIS has evidently not only been adhered to by successive architects, but that they have carried out their work in complete harmony, as regards scale, with that previously executed. Therefore, on the grounds of the directness of its well-conceived plan, its singleness of purpose, its unsurpassed mastery of the relation of solid to void in its construction and remarkable unity of expression, may it not be said that the cathedral church of Rheims is one of the greatest of Gothic structures, and is probably the one in which perfection as a whole has been most nearly attained?

SPECIFICATIONS.*

THE preparation of a specification, as a preliminary to entering upon a contract for engineering works, is unquestionably one of the most important of an engineer's duties, requiring very complete experience and thorough technical knowledge for its satisfactory accomplishment; yet some specification writers display a fine disregard of the true function of such a document, and show a child-like faith in the ability and generosity of the contractor, which, although very flattering to him, does not say much for the business instinct of its professors.

In this paper some of the points that are essential to the production of a specification which shall properly fulfil its purpose are touched upon, and this purpose is to amplify the contract drawings by giving detailed descriptions of the materials to be used, the methods of preparing and using them, and other information which cannot be conveniently written on the drawings themselves. The two main divisions of an ordinary specification are the conditions of contract and the specification, properly so-called. The form of tender is not infrequently attached.

The conditions of contract, as their name implies, form the legal part of the document, as distinct from the technical description of work to be done, but it cannot be too clearly borne in mind that the whole of a specification, when duly signed by the parties to the contract, is a legal document which must be produced in Court if a dispute should unfortunately arise with reference to the works; and it is, therefore, of the utmost importance that it should be lucidly written in simple language, the clauses being arranged in logical sequence, and the descriptions exact and complete without being needlessly verbose. Every item of work should be allotted a separate clause, for when a single clause includes descriptions of several different matters confusion must ensue.

A complete alphabetical index, with the clause and page numbers attached, will be found to be (especially in the case of a lengthy specification) a great help in quickly finding any required subject, and cross references may sometimes be introduced with advantage.

Brevity, so far as it is consistent with completeness, being the hall mark of a good specification, no information should be introduced which may be clearly obtained from the drawings, the intention being that the drawings and specification are to be taken together, and a clause to this effect is sometimes inserted. On the other hand, it is waste of labour, besides being confusing, to put descriptive matter on the drawings which would be better included in the specification; and a mistake which is frequently made is to duplicate information in this way, obscuring the drawings with unnecessary writing, and overloading the specification with identical information.

A very common fault in specifications is indefiniteness of description, and this generally arises from the writer not having a clear notion of the work or materials which he attempts to describe, though in some cases it is due to the obscurity of the language, or to the misuse of certain words, especially "proper" and "sufficient." The engineer should know what is proper and sufficient, and should describe it in precise terms, otherwise he is only opening the way for trouble when it becomes necessary to find the meaning of these words in terms of actual materials and workmanship. The word "etcetera" should be rigidly excluded, and the matters covered by it clearly defined.

It should be hardly necessary to say that the drawings must be completed and inked in before the specification is written, or at all events before it is finally completed, as any other procedure will almost inevitably lead to more or less important omissions, with the result that "extras" will be writ large in the contractor's little bill. It is an advantage, when time permits, to have the detail drawings (if any) completed at this stage, as it is not unusual for important modifications to be found necessary when the details are got out on a larger scale. The drawings should, of course, be numbered, dated, initialled by the draughtsman, and signed by the engineer; and it may sometimes be useful to have reference letters or numbers on certain portions of the drawings, which may be alluded to in the specification.

An inexperienced writer of specifications is very apt to be uneven in his description of the work, writing with unnecessary verbiage on those matters with which he is familiar, and dismissing some equally important point with

* A paper entitled "Specifications for Engineering Works," read by Mr. H. Laurence Butler, M.J.Inst.E., M.R.S.I., at the last meeting of the Civil and Mechanical Engineers' Society.

Digitized by Google

a brief direction that "the work shall be done to the satisfaction of the engineer." A general direction of this kind usually implies that the engineer does not know what he wants, and therefore leaves the matter to the superior knowledge of the contractor—an attitude not very creditable to the former.

The only really legitimate use of this phrase is in a general clause referring to the whole of the works. An example of uneven description within the knowledge of the author exists in the specification for certain works of sewerage, in which the tests for Portland cement occupy a half-page of closely printed foolscap. None of the tests were applied, and apparently they were not intended to be applied, but the whole description was taken *en bloc* from another specification, presumably with a view to overawing the contractor. In the same specification the description of some pumping machinery at the disposal works appears to have been copied direct from the estimate of a firm of mechanical engineers, only the prices being left out, and the curious commercial brevity of the phraseology, comprising such phrases as "including all necessary fittings complete," stands out in striking relief from the rest of the document.

It is evident, then, that one of the most essential qualifications for a specification writer is a thorough knowledge of his subject, and he should have also a sufficient command of the English language to enable him to express his meaning clearly and tersely. It is quite unnecessary to indulge in legal jargon and high-sounding phrases which the writer possibly does not understand, and it is by no means a fault to repeat words again and again if they express the meaning of the writer more clearly and forcibly than an alternative phrase would do. A specification is seldom judged by literary standards of excellence.

It is also necessary that the specification writer should have a thorough knowledge of trade customs, such as discounts (in order to define "prime cost"), the methods of measuring timber and scantlings, the different modes of dressing masonry work, whether the word "best" applied to certain materials will really mean best, or if by trade custom it may be taken to mean an inferior quality. Moreover, in the case of structural work, he should make himself acquainted with the regulations in force in the district in which the building is to be erected, and should make it clear in the specification if the contractor is to take the responsibility of complying with the local authority's requirements or otherwise.

Another error which may occur through inexperience is that of specifying impracticable sizes of materials, such as timber and metals, and this may also occur when clauses are copied from obsolete or badly written specifications. The method of compiling a specification on the "scissors and paste" principle, by taking clauses from old specifications, is one that will lead an inexperienced writer into error more quickly than any other, because if he has any doubts as to the reliability of the description, it will be more or less discounted in his mind by the fact that that particular clause has been used before, regardless of when or under what circumstances it was used.

The degree of detail which a specification should contain is governed very largely by the magnitude and importance of the work, as it is obvious that the detail in the specification for a 50,000*l.* contract would be merely a display of misdirected energy if applied to the specification of works costing, say, 500*l.*

A practice which should be studiously avoided wherever possible is the specifying of alternative workmanship and materials. It is far better to be exact in defining what is to be done or supplied, because it then affords no ground for dispute or difference of opinion. However, with regard to the actual methods of carrying out the work, the contractor should not be tied to any particular means of effecting the required end, unless special circumstances require it, for, provided the materials and workmanship are satisfactory, it is better to allow the contractor to use his own discretion as to the manner of producing the required result.

The arrangement of a specification is generally as follows:—

(1) Conditions of contract and general regulations applying to the whole of the works.

(2) General description of materials and workmanship, excluding purely local or particular directions.

(3) Detailed description of the various portions of the work, systematically arranged.

The conditions of contract usually begin with a definition clause, which, in order to obviate needless repetition, defines such words as "employer," "engineer," "contractor," "prime cost," and similar matters. Other clauses enumerate the conditions to be observed in carrying out the works, and make the contractor responsible for giving notices required by the local authority, require him to sign the drawings and specifications within a given time from the acceptance of his tender, to provide sureties for the satisfactory completion of the work, and to commence the work within a stated period after receiving notice from the engineer to do so.

A very useful clause is that empowering the engineer to vary or alter any part of the works without vitiating the contract, and a clause requiring the contractor to render weekly accounts in writing of all omissions, extras and variations, greatly assists the engineer in deciding what payments may be made from time to time on account of work done, as well as in the final adjustment of accounts.

Other clauses may refer to the method of ascertaining prices for extra works, the power of the engineer to take samples for testing purposes, the opening up of work for inspection, the prohibition of assignment or subletting of the contract, responsibility for accidents, time for completion, period of maintenance, suspension of works through various causes, mode of payment, engineer's certificate of completion, and other matters of this nature, the conditions usually concluding with a clause providing that all disputes may be referred to an arbitrator for settlement.

It is not unusual, however, to have, in place of the arbitration clause, a condition that the engineer shall have the exclusive right to authoritatively determine the meaning of the contract. Such a provision is, perhaps, rather unsatisfactory from the standpoint of the contractor, who may be inclined to consider the engineer unsuitable to act in this capacity, by reason of the fact that the latter has generally formed an opinion on any dispute which may arise before the matter is referred to him for settlement; but unless it could be demonstrated that the engineer's opinion was not open to argument or reconsideration, or that he had deliberately shown prejudice or partiality, the Courts could scarcely be persuaded to declare that he was unfit to be arbitrator. The chief advantage of the clause, from the engineer's point of view, is that it supplies a summary means of remedying the faults and supplying the omissions in a badly drafted specification. It would appear that the arrangement most satisfactory to all parties is for the engineer to have the final decision as regards workmanship and materials, and to provide for appeal to an external arbitrator on all matters relating to payment, such as the amount of extra works, loss to the contractor through delay or alteration of the works, and similar questions. A further modification of this provides that no appeal to an outside arbitrator shall be made during the progress of the works, but that disputes on any matter arising out of the contract shall be temporarily decided by the engineer, and his decision shall be binding on all parties until the completion of the works, after which the matter (unless explicitly reserved for the final and binding decision of engineer, without appeal) may be brought before a referee. This arrangement is designed to prevent any disputed matters from causing delay in the execution of the works.

In alluding to the drawings, it is a good plan to add a paragraph to the effect that figured sizes are to be followed in preference to the scale dimensions, except in cases of obvious clerical error. The clauses enumerated above do not by any means exhaust the list of provisions that it may be necessary to make in the case of a large contract, and in very small works some of the clauses may be reasonably omitted, but they are mentioned as being generally applicable to contracts of moderate size.

The specification proper usually begins with a description of the site of the works, specifying any unusual features which may exist; and if the site is very inaccessible, involving a great deal of haulage work, it is an excellent thing to provide a key plan, showing the distance from the nearest station, and marking on it any unusually steep hills, bad roads, or other circumstances likely to affect the cost, although some engineers prefer to let the contractor find out all these things for himself, and insert a clause in the conditions to the effect that "the engineer cannot be held responsible for any incorrect information supplied."

The next clause generally enumerates the drawings, giving the number and title of each one, with the words "and such further detail drawings as may be supplied by the engineer to the contractor from time to time." Then follows the description of materials and workmanship applying to the whole of the works, and including such matters as cement, sand, mortar, concrete, bricks, brickwork and the

Digitized by Google

like, leaving the particular description of the individual parts of the work to be dealt with later.

The general description may conveniently conclude with a clause requiring the contractor, before commencing the work, to deposit with the engineer a sample of each kind of material intended to be used, all materials employed in the execution of the works to be equal in quality to the samples so deposited.

The remainder of the specification consists of detailed descriptions of the different parts of the work, subdivided under general headings. A systematic arrangement of this nature tends to exclude the probability of any serious omission, and assists any subsequent reference to the specification. Printing a brief note of the contents of each clause on the margin of the page is a convenience when it is desired to refer to any particular item, but it should be made clear that these marginal notes are merely auxiliaries, and do not form part of the specification any more than the index does.

Another arrangement is to divide the work up under the headings of various trades, such as "Excavator," "Bricklayer," and so forth, the general description of materials preceding the detailed enumeration of particular items under the heading of the appropriate trade. This method is usually applied only to specifications for building works.

Some engineers and architects advocate the free use of marginal sketches to further elucidate the intention of the written description, but where the specification is printed this method is inapplicable, owing to the extra expense involved in printing, and in any case it is doubtful whether such details would not be better demonstrated on the drawings. A competent specification writer should be able to describe his meaning with sufficient clearness to enable him to dispense with such a superabundance of illustrations. In the case of any very complicated piece of work, a detail drawing to scale is obviously of more utility than a mere sketch, and in simpler cases a written description should be all that is required.

Trade catalogues form one of the most useful items in the specification-writer's stock-in-trade, and here again the advantage of system will be apparent. A complete set of trade catalogues filed on the decimal system, and accompanied by a card index in two divisions, one of subjects and the other of names of firms, will enable the engineer to turn up at the shortest notice the information with regard to any manufactured article that he may require, and to make a comparison between the manufactures of different firms, with a view to finding the particular article best suited to his purpose.

In this connection it may be said that the practice of specifying that certain articles shall be supplied by a particular firm is one that should not be carried to excess. It is not an unheard of thing for a manufacturer, who has been specified to supply certain goods, to raise his prices for the occasion, but if estimates are obtained from firms of equal standing and reputation, it is generally possible to obtain a lower price than if the other course were adopted. The selection of one firm to the exclusion of all others may also suggest unfairness on the part of the engineer, and may create the idea that his selection is not without profit to himself, although it is to the credit of the profession and the manufacturers that cases of bribery are so extremely rare as to be practically non-existent. It may here be remarked that a good commercial knowledge (including the ability to price out roughly the present market value of any ordinary materials and labour) is a distinct advantage to a specification writer, enabling him when selecting goods to thread his way through the maze of trade discounts, discounts for cash, and special discounts for large quantities with which some merchants conceal the actual cash price of their manufactures, especially as in some cases it is not unlikely that he may be called upon for advice upon particular items when the settlement of accounts takes place.

A matter which too seldom receives thorough consideration is the question of what part (if any) of the materials for the works can be obtained locally. The practice of specifying goods which must necessarily be conveyed long distances before they can be utilised, while equally satisfactory materials can be procured near the site of the works, argues negligence on the part of those responsible for drafting the specification, and is usually due to culpable ignorance of local conditions. As illustrating this point, a case may be mentioned where a contract was secured at abnormally low prices, the contractor making a good profit by utilising the sand and gravel obtained from the excavations, which other less wideawake contractors had counted upon having to bring several miles by road. In this instance it was even hinted that the contractor went to the extent of carting away alleged "surplus material" from the site, which he afterwards turned to his own use and profit.

Although the preparation of bills of quantities does not form part of the work of writing a specification, it may not be out of place to mention that attempts have been made in the past to combine the two documents in one, but as each has an independent function, any attempted combination must be unsatisfactory. The bills of quantities are merely schedules of labour and materials, arranged so that prices may be conveniently attached, and the endeavour to make them serve another purpose is inevitably foredoomed to failure. Moreover, if the quantities are made a part of or annexed to the contract, and any dispute should arise, the Court may hold that the contract on the builder's part was not to complete the works, but only to execute the quantities.

It is not possible within the limits of this paper to touch upon all the points which may arise in connection with preparing a specification. Enough has been said to demonstrate that specification writing is worthy to rank high amongst other showy, but scarcely more interesting, professional work. Indeed, it requires for its satisfactory accomplishment a high degree of technical knowledge, something more than a smattering of legal information and a sound commercial training. If, in addition, the specification writer possesses plenty of sound common sense, allied to practical experience in his work, he will be well fitted to assist in dispelling the much too popular fallacy that the preparation of specifications is a necessary but uninteresting piece of drudgery, carrying with it no reward but that which always accompanies work well done.

GLASTONBURY ABBEY.

MR. F. BLIGH BOND, F.R.I.B.A., who during the past year has directed important excavation work at Glastonbury Abbey, delivered a lecture on the result of his explorations at the Taunton Castle Museum on the 7th inst., under the auspices of the Somerset Archæological and Natural History Society.

Mr. Bligh Bond at the outset of his illustrated lecture, said the subject needed no apology from him for bringing it forward, as it was one of intense interest to all patriotic people; it was, in fact, of interest to the nation as well as to the Church. His lecture would principally deal with the architectural features of the Abbey, and he had brought a set of lantern slides. The ruins were so far advanced in decay that to the casual observer it was extremely difficult to make out the plan of the whole building, and in the absence of so much of the fabric it was difficult to form a picture of the church as it stood complete. Describing St. Mary's Chapel, he remarked that it was acknowledged on all hands to be the most beautiful work of the period in the country. It exhibited a studied refinement and a great degree of imagination, and the character of the building confirmed one's view of the really holy nature of the place. Its construction and decoration formed enough evidence to show that there was some good reason for the veneration of that spot. They all knew the tradition that the first Christian church in England was founded at Glastonbury, and was a wattled or wickerwork church, a reputed picture of which had come down to them. The wicker church was supposed to have been standing in the eleventh century, and to have been destroyed in the great fire of 1184. After alluding to the unsuccessful excavation work undertaken in 1904 on behalf of the Royal Archæological Institute, Mr. Bligh Bond went on to describe the result of his own researches. He had come to the conclusion that the chapel of St. Edgar, which had been the work of the last two abbots, was much larger than had been supposed. In an inventory sent to Queen Elizabeth the full length of the church was given as 594 feet, 90 feet being entered as the measurement of the chapter-house. He considered that a mistake had been made in that particular, and that by chapter-house the east end chapel was meant. Following the lines of the walls according to the old plan they found on excavating that beyond there was something more. The foundation lines of a rectangular chapel, 49 feet long, had been worked out, and portions of the stone work were discovered. The excavations showed that the chapel must have been a very substantial building, and had been connected with the choir of the great church. The discovery of the chapel, however, did not satisfy the inventory, as it only brought the total length

Digitized by Google

up to 580 feet, and when the work was resumed it was expected that they would find there was an annexe at the east end. Several objects of interest had been discovered during the excavations, and these gave additional corroboration of the existence of the chapel. St. Edgar's Chapel was, no doubt, one of that class represented by the magnificent chapels of Westminster Abbey, with massive stone walls and stone roof of the fan tracery type, while the walls were supported by substantial buttresses. The work was probably similar to the chapel of Henry VII. at Westminster. Before concluding, Mr. Bligh Bond described a strange interment found close to one of the walls of the church. It was a complete skeleton with the head set in a stone shaped for that purpose, but with no covering, and nothing to show that there had been a coffin. The remains, which were discovered perfectly preserved in the clay, were those of an elderly man, measuring 6 feet 2 inches in height. As to further excavations there was plenty of work to do next summer. Last year about 43*l.* was subscribed, which money lasted until the end of September, although the work was continued, as they had great faith in being able to get sufficient support.

In response to a question in reference to the discovery in St. Edgar's Chapel of an old piece of wattle work, which might confirm the story of the early chapel of St. Mary, Mr. Bligh Bond replied that they had found during excavations signs of some early habitation, including the burnt stone of the hearth and the curious wattle work referred to.

Correspondence

[*The Editor will not be responsible for the opinions expressed by Correspondents.*]

Winchester Cathedral.

SIR,—I read with some surprise in a copy of *The Architect* the account of the work in progress at Winchester Cathedral. Your informant says that we are still making discoveries. I am not aware of anything new having been found out lately in regard to the condition of the fabric. He says:—"Having underpinned the two corners of the north transept, it has been found that the wall between them must be underpinned also." This is simply what has always been intended. Because we began at the corners it does not follow that we meant to stop there. One must begin somewhere.

He proceeds:—"Another discovery is that the buttresses of the north aisle do not support but hang on the wall." This discovery is not new. It was made, if I remember, two years ago.

He adds:—"As this was known to be the case with buttresses at the east end of the church several years ago, the recent discovery is somewhat belated." Your informant is entirely mistaken. It is not the case with any buttresses at the east end; and had it been so, I fail to see any analogy between the two cases.

More amusing still is his apprehension that the cement injected into the walls may find its way into the peat. It would indeed be strange if grout injected into the superstructure should find its way through solid masonry to a stratum of peat 10 feet below ground. All fissures are, of course, stopped at the bottom first, and then continuously upwards; and as a matter of fact there is no peat left under the wall, for it is removed to make way for our underpinning.

It seems to me that these captious criticisms, based on imperfect knowledge and on erroneous information, are much to be deplored. The repair of Winchester Cathedral may fairly claim the sympathy of all lovers of our English art. No one is more sensible of the responsibility attached to it than those who have charge of the building and those to whom the work is entrusted. To spread abroad such misstatements of fact and such unfounded criticisms as those I have exposed is neither fair nor generous.—I am, Sir, your obedient servant,

THOS. G. JACKSON.

14 Buckingham Street, W.C.: January 11, 1909.

Earthquake-proof Houses.

SIR,—I note Mr. Wray's letter on earthquake-proof houses seems to lose sight of the essentials of the American system of steel-framed buildings as set forth in Freitag and other authorities, viz. that of cross-bracing the end bays, which is a means of triangulating the angles. It is a deplorable fact that at Messina it is the invariable habit of the local builders and architects to build massively on self-supporting stones, and to a height of six and seven storeys. My opinion is that towns within the earthquake zone should not be constructed above three storeys from the ground, and then on a basement in the form of a groined vault.

The system adopted by Mr. Wray would be much improved by building the walls of concrete on an expanded metal mesh. I have designed many such buildings, and even for concert halls for South America and Africa, which have been despatched out ready for erection in crates. There is room for artistic display and balconies and large eaves to roofs obtained without much structural alteration. —I am, yours truly,

43 Chancery Lane, W.C. ALBERT E. BULLOCK.

P.S.—With reference to the extensive correspondence on the subject of Lord Leven's bequest for the restoration of Holyrood Chapel, may I ask whether it is known if there are any drawings extant showing the work of Nicholas Stone in 1616?

"Jully 1616 was I sent into Scotland, at Edenborrow, where I undertook to do work in the Kinge's Chapell and for the Kinge's closet and the organ so much as com to 450*l.* of wenscot work, the which I parformed and had my money well payed, and 50*l.* was geven me to drenk wharof I had 20*l.* geven me by the Kinge's comand." (Quotation from Stone's diary.)—A. E. B.

SIR,—I trust that in writing a criticism—wholly friendly or at least unbiassed—on some of the matter contained in your very interesting current number I shall not be esteemed as hypercritical. I say unhesitatingly that I have seldom, if ever, read a more interesting issue of *The Architect*—if I except those to which I may have contributed—but I have been trying to puzzle out a solution (and have not succeeded) as to the merits of Mr. Wray's suggested anti-earthquake panacea, and of Mr. Allsop's views (as expressed) on architectural principles.

What is there in 12 inches of concrete, or in twice 12 inches, to obviate such a disaster as that which has befallen Messina, Reggio and neighbouring districts? When Mr. Wray makes an exception to the value of his scheme to the effect "unless the shock was sufficient to turn the house completely over," does he imply merely turtle-turning, or is side-slipping included? But my—perhaps limited—intelligence fails to see how a house can "turn completely over." As a scientific experiment I should very much like to witness such a demonstration. Again, what is an "earthquake seam," and is it "reasonable to believe that the combustion would glide off to the edge of the concrete before shattering the house"? Besides, if it is going to shatter the house, why trouble, in the first place, to "glide off to the edge of the concrete"? I perceive that Mr. Wray inserts the words "if the said foundation is sufficiently strong," but that is begging the whole affair. Concrete, again, is not a damp-proof foundation; it is merely to an extent damp-resisting, which makes all the difference in the world.

I am by no means scoffing at Mr. Wray's wish to find a solution that may minimise the fearful results of seismic disturbances, but I fear that more consideration is necessary than that provided by a suggestion of 12 inches of concrete.

And Mr. Allsop. What can one say of his initial essay on Principles of Architecture? Within the last two years there have been published two books and various essays on the subject, and these have, as one would think, fairly set forth the basis of consideration. Architecture "a pure abstraction"? Absurd. Mr. Allsop is more in order when he says it is often "congealed discord"; but if congealed, how can it be an abstraction? Again, "in modern architecture" we do not miss "broad effects," at least not in the architecture of the very present day. I would add more, Sir, but have already, I fear, unduly trespassed on your valuable space.—Yours obediently,

NASCITUR, NON FIT.

The R.I.B.A. Dilemma.

SIR,—I am glad to see from your note that you have taken up such a strong position in connection with the Royal Institute of British Architects; the paragraph is firm with-

Digitized by Google

out being in any way unpleasant. We are, I trust, all proud of the Institute, and proud of the men who devote their time to its management, but this does not say we should be compelled to agree with every act of theirs, and although minorities should always have and receive every consideration, this instance is a case of the minority ruling, a position which is absolutely untenable. Pardon the liberty, if such it is, but permit me to congratulate you on your last issue. Trusting 1909 may be a very prosperous year,—I am, yours faithfully,

A.R.I.B.A.

Concrete Aggregates.

SIR,—It is interesting to note from the interim report of the Special Commission on Concrete Aggregates which appeared in your issue of January 8 that this important matter is receiving the consideration it merits. From an architect's point perhaps the most important section of the inquiry is that which deals with the lighter aggregates used in the making of suspended concrete. Since the extensive adoption of iron in our modern buildings, dictated by the necessities of increased protection from fire, the matter of light concrete has become an important factor, and whilst elaborate specifications and standards have been prepared for the cement and other binding material, the question of the equally important aggregates has received little attention. Noting the suggestions of specification for coke breeze, slag and clinker contained in the report, it will be interesting to learn how the proportion of sulphur which is inseparable from these forms of aggregates is to be determined in actual practice. In a laboratory the process is easy, but those who have experience in carrying out a superintending work know full well the difficulties which will attend the testing of the bulk as delivered in the work or in the blocks and slabs after they are made. The difficulties are increased by reason that the sulphur is incorporated throughout the particles and cannot be displaced by washing, and its effect is not discernible for a lengthy period after the concrete is made; certainly not before the process of permanent hardening (as distinct from the initial set) has sometime commenced. Disastrous results owing to the presence of sulphur have occurred after a long lapse of time in work which showed no indication of deterioration until the building was completed and occupied. It is gratifying to find that the quite recent suggestion of pumice gravel as a light aggregate has found a place amongst the materials with which tests are to be made, and it is anticipated that the results will bring about the adoption of that material, which, whilst possessing all the advantages of burnt carbon materials, has none of their disadvantages.

Tests extending over two years have already been made with this material and satisfactory and permanent results obtained.—Yours faithfully, M. C. I.

GENERAL.

The Royal Scottish Academicians—Sir James Guthrie presiding—have decided to elect a painter in room of Mr. George Henry, who has requested his name to be placed on the non-resident list of members. The election will be made on February 10.

The Billericay (Essex) Rural District Council offer 10*l.* 10*s.* as a premium for plans and estimates for four and six-roomed cottages, of which there is a serious dearth in Essex.

Mr. Joseph Henry Richardson, architect, 22 King Street, Hammersmith, died suddenly on Sunday. He designed the Hammersmith town hall and Council offices, and had much to do with the growth of the district.

The Committee who have the question of improving the Newport Bridge, Mon. (of which we published a report last week) in hand, are of opinion that an expert bridge engineer should be consulted in the matter, in order that his opinion may be ascertained as to the stability of the present structure and as to the necessity, or otherwise, of its early renewal. It has also been agreed that should it be the opinion of the engineer that the bridge requires renewal at an early date, he should be asked to advise the Council what material should be used. It was resolved that Mr. G. E. W. Cruttwell, C.E., a partner of Sir John Wolfe Barry, should be consulted.

The Blackburn Small Holdings and Allotments Committee have decided to invite architects and surveyors in the borough to submit competitive plans for the laying out of the estate at Oswaldtwistle recently purchased for small holdings. Premiums of 25*l.*, 10*l.* and 5*l.* are offered.

Mr. Stead, late of Natal, and formerly assistant surveyor under the Lancashire County Council, has been appointed assistant county surveyor to the Somerset County Council.

The Manchester Art Gallery Committee has adopted a scheme for acquiring a collection of slides representing the undoubted masterpieces of arts and crafts. The slides are to be kept at the art gallery and lent out to literary societies and other bodies for use in lecturing and other educational purposes.

The School of Art Wood-Carving, South Kensington, has removed to new premises at 39 Thurloe Place, South Kensington, three minutes from South Kensington Station. Students connected with the wood-carving trade and professional teachers are admitted to the school at one-half the full fees, provided they attend regularly during the usual school hours, unless absent with the written permission of the manager.

Mr. A. G. Temple, F.S.A., director of the Guildhall Gallery, has received the freedom of the Worshipful Company of Painters in recognition of the public services he has rendered, in many directions, in the interests of art. The ceremony took place in the ancient hall of the Company in Trinity Lane. Only three individuals have been so honoured during the last twenty years—the late Lord Leighton, P.R.A., Sir E. J. Poynter, Bt., P.R.A., and Mr. Andrew Carnegie.

Mr. Butler Wilson, F.R.I.B.A., of 45 Gower Street, W.C., and Greek Street Chambers, Leeds, is preparing a sketch of the life and work of the late Cuthbert Brodrick, the architect of the Leeds town hall. He has in his possession the designs for several important buildings executed by Mr. Brodrick. There must, however, be in existence other designs prepared by him, and Mr. Wilson would be grateful if the owners would allow him to see them. The greatest care would be taken of them, and they would be returned as soon as they have been examined.

The Council of the National Museum of Wales held a special meeting last week at the Cardiff city hall. Arising out of the discussion of the draft Bill to take over the Cardiff Museum, with its responsibilities, the question of Mr. Edwin Seward's claim upon the Corporation for the preparation of plans for a museum was considered. A unanimous feeling was expressed that the Council could not accept any responsibility with regard to that claim. The Council decided to inform the Cardiff Corporation that they were prepared to take over the contents of the Cardiff Museum free of all debts and liabilities, and Principal Griffiths gave notice that he would at the next meeting move that plans for the National Museum be offered to public competition. He hoped that by doing this it would bring to an end the long-standing dispute between the Cardiff Corporation and Mr. Seward, F.R.I.B.A.

The Art Gallery Committee of Aberdeen have purchased six works for the permanent collection in the gallery from the exhibition of the Aberdeen Artists' Society. The works, with the catalogue prices, are:—"At Eventide," by Mr. J. Coutts Michie, A.R.S.A., 60*l.*; "Almost Night, Concarneau" (water-colour), by Mr. Terrick Williams, R.I., 15*l.* 15*s.*; "Glen Clova," by Mr. Alec Fraser, Aberdeen, 100*l.*; "The Little Court," by Mr. William Smith, jun., Aberdeen, 10*l.* 10*s.*; a bronze bust, "Enid the Fair," by Sir George Frampton, R.A., 50*l.*; and a bronze head, "Frametta," by Mr. Henry Wilson, 25*l.*

The Royal Institute of Architects of Ireland held their January Council meeting on the 6th inst. A letter was read from the secretary of the Dublin University Commission asking for a detailed statement of the subjects and courses of study suitable for students seeking diplomas in architecture. It was decided to hold a special Council meeting to consider the matter. In the course of the meeting the following resolution was passed:—"The Council of the Royal Institute of the Architects of Ireland note with satisfaction that the Galway County Council have lately resolved to require their county surveyor to devote his entire time to the duties of his official position, and the Council of the Institute take the opportunity of expressing the hope that a similar resolution, but including also the assistant county surveyors may, without delay, be passed by every County Council in Ireland who have not already done so, inasmuch as it is contrary to the interests of the public service that persons holding the important and responsible position in question should engage in professional competition with architects and engineers in private practice, upon whom, moreover, such competition inflicts a serious injustice, which they, as ratepayers, are justified in strongly protesting against." A copy of this resolution was ordered to be sent to the secretary of every County Council in Ireland.

The Architect.

THE WEEK.

To the lover of architectural art the news of the earthquake shock in Northern and Central Italy is even more alarming than the dire catastrophe in Sicily. Although happily the damage so far recorded is comparatively insignificant, the fact that the chief severity of this new seismic disturbance was felt in Venice, Verona, Padua, and Milan arouses our liveliest apprehension. Those of us who have visited Venice cannot but remember that scarcely one of its many campanili is truly perpendicular, whilst the wooden piles on which rest the foundations of its architectural masterpieces, not only of the Mediæval period, but also of the Renaissance, have in many instances quite or almost reached the limit of their durability, and it is only the fact of the close proximity in which they are grouped together that has prevented their failure long ere this. To buildings in this sensitive condition a severe shock of earthquake is likely to prove disastrous, and the knowledge that these charming old towns of Northern Italy are situated on the line of possibly severe earth movement is disquieting in the extreme.

IN April next will be opened in Venice the Biennial International Exhibition of Fine Arts, and, as usual in matters of art, official assistance in England is not forthcoming, although other Governments have given adequate support. Private generosity must therefore rectify the omission on the part of our own Government, and Sir DAVID SALOMONS has liberally given the 3,000*l.* required for the purchase of a pavilion. Additional funds are still required for the proper exhibition of British art, and an appeal has been made to the public for the necessary cash. Donations may be sent to the hon. treasurer, Mr. MARCUS B. HUISH, 21 Essex Villas, Kensington.

BEFORE the Royal Commission on Ancient Monuments in Wales and Shropshire some interesting evidence was given by Mr. GEORGE EVANS, who spoke of the many interesting things to be found in the eighteenth-century churches and chapels of Wales. A walking tour in some of the out-of-the-way parts of the Principality would doubtless furnish some of our younger architectural students, who are nowadays keen on Renaissance detail, with many subjects for their sketch-books, as well as afford them the advantages of fresh mountain air and beautiful scenery. They should take advantage of Mr. EVANS's tip that the rural policemen and village schoolmasters are useful sources of information.

MANY architects, particularly those whose earnest student days have been included in the last quarter of a century, must have regretted to hear of the death of Professor H. G. SEELEY, who occupied the Chair of Geology at King's College, London, and who conducted the London Geological Field Class for the last twenty-three years. It is to be hoped that this class may still be continued under capable leadership, for amongst the many things, of which a modern architect ought to know something, is geology, and to those whose practice will or may be carried on in the metropolitan district, the study of London's geological character is of some importance. The subsoil of London, even of the central area, still more of Greater London, is very far from being an uniform, impervious, homogeneous lump of London clay.

IT is a pity that the 150th anniversary of the foundation of the British Museum could not have been celebrated by the opening of the important extension now in progress from the designs of Mr. J. J. BURNET. Since Montagu House and its grounds were bought for 10,000*l.* for the housing of the Harleian Manuscripts, the Cottonian Library and the Sloane Collection, growth, whether of acquisitions or of accommodation, has been continuous, but from an architectural point of view few of the treasures added to the national collection have equalled in interest and value the Elgin Marbles. The high importance of these has, it is true, rather eclipsed the light of many other instructive antiquities, particularly the remains of architectural and sculptural work of the provinces of the later Roman empire, including those preserved from the Roman occupation of our own country. We are looking forward to the completion of Mr. BURNET's work, when we may expect to see properly displayed the many treasures that are now huddled together and hidden away in the basement.

Il Monitore Tecnico gives some illustrations of the latest design of the many that have been made by various architects during the last twenty-five years for the Chamber of Deputies of the Italian Parliament, for which the building on Monte Citorio, erected from the designs of BERNINI, is to-day insufficient. The design now under contemplation is that of Signor BASILE, who proposes to preserve the work of BERNINI and FONTANA and to complete the cortile with one wing on the Via delle Missioni, another on the Via dell' Impresa, and the completing block with the principal façade towards the new piazza. The particular parts of the design illustrated are this principal façade, from a drawing of the elevation, and the interiors of the Chamber and the Salle des Pas Perdus, from models. The elevation is a quiet and sober composition, which rather lacks any principality of feature or grouping, and in which the detail, as far as can be observed from the very small scale, appears to be reminiscent of the early manner of BRAMANTE, modernised in treatment.

SIGNALISING the centenary of the Conservatorio di Musica Giuseppe Verdi, at Milan has been recently opened a new concert hall 43 metres long, 26 metres wide, and 16 metres high, erected from the designs of Signor BROGGI, architect, and Signor NAVA, engineer. Balconies some 24 feet wide project from the outer walls on three sides, and, constructed in reinforced concrete, are partly carried by vertical piers, also in reinforced concrete, these latter being continued up to the level of the ceiling, which is flat. The floor of the hall is also in reinforced concrete, carried on brick piers.

IN Germany they have always seemed to be badly bitten by the craze for "L'Art Nouveau," the eccentricities and extravagances of which seem to have caught the fancy of our Teutonic colleagues, whilst the spirit of rebellion against precedent and academic regulation has naturally captivated the imagination of those whose early experiences in school, in college, and in the army have been chiefly marked by continual subjection to martinet authority, and who have been dragooned throughout their career to rigid formalism. The fascination of bizarrerie which led the sixteenth-century Germans to found their national treatment of Renaissance on the least correct phase of early French work, and to continue that treatment until the latest development in Latin countries gave them an opportunity for supplementing their first line of effort by the Barock style, has also no doubt played a part in the eagerness with which the New Art has been seized upon in the Fatherland.

THE attempt to be easily original by ignoring all precedent and devising something too eccentric to have ever been done before by more truly artistic workers, has led to the many extravagances of the earliest productions of the new mode. The exponents of this mode have overlooked or never learnt the truth so well expressed by RODIN:—"L'originalité, telle que l'entend le public, n'existe pas dans le grand art. Les artistes qui n'ont pas la patience d'atteindre au vrai talent recherchent la bizarrerie, la singularité du sujet ou des formes, en dehors de la vérité. C'est ce qu'ils appellent de l'originalité, mais ça ne sert à rien."

STUDENTS' DRAWINGS AT THE ROYAL INSTITUTE.

TAKEN as a whole we fear that we must say that the students' drawings this year are not up to the high-water mark of past history; but nevertheless good work has been done by all the prizewinners, and, except in one case, we think the first prize in each competition has been awarded to the best man. The one exception in which we are disinclined to agree with the award is that of the Institute silver medal and ten guineas for measured drawings of ancient buildings in the United Kingdom or abroad. The prize has been given to the one competitor who has gone abroad for his subject, and it would appear that the student who desires to win this particular medal must place first and foremost inaccessibility of subject as the prime factor of success. We cannot agree that for a British architectural student the church of the Madonna di San Biagio, Montepulciano, the work of ANTONIO DA SAN GALLO the elder—a far less able man than the younger of the same name—is as worthy of study as some of the other buildings illustrated—as the Royal Naval College, Greenwich, the work of INIGO JONES; as the parish church of Lavenham, one of the finest examples of our late Perpendicular work; or ADAM'S work in the Royal Infirmary and DAVID DALE'S house at Glasgow. Nor can we recognise that either the draughtsmanship or the industry of Mr. ERNEST W. WRAY, the winner, is, to put it mildly, markedly superior to that of some of his competitors. Montepulciano is a fine name, and rolls as beautifully off the tongue as "that blessed word, Mesopotamia," but we take it that the chief charm of Montepulciano lies in the picturesque situation of its church and the excellence of its wine. The architectural merit of the design, particularly in detail, of the church of the Madonna di San Biagio is not, to our thinking, with all respect to the opinion of the late Mr. ANDERSON, transcendent; and save, as we said before, for its inaccessibility, does not merit prolonged study on the part of a young architectural student.

The Soane Medallion, with a travelling studentship of 100*l*., has brought out ten sets of drawings for a casino on the borders of a lake, and the winning design, by Mr. A. R. BARKER, has an excellent plan, in which the concert hall, with promenade around the auditorium, is surrounded on all sides by a series of rooms en suite, quite the best arrangement for a casino, and far superior to the rambling plans of the other competitors. The composition is good, with a low central dome over the concert hall, dominating the whole; and the detail is a sufficiently free treatment of Renaissance to give a casino-like expression without being over-exuberant. In the design placed second—that of Mr. ADRIAN BERRINGTON—the plan occupies three sides of a quadrangle, the concert-room in the centre with the other accommodation in the wings, hence disassociated. The exterior is treated in a severe Italian manner, and its restraint must have been felt a relief by the judges after the extravagances of some of the other designs. The winning design is undoubtedly first, but several run the second rather close in our opinion. "Pan" is a good design, but somewhat chaotic and restless in composition from the multiplicity of features. The plan is virtually three buildings, the concert hall in the centre being flanked by a club on one side and a corresponding building containing billiard-room and restaurant on the other. We fear the author has been rather misled by a desire to make a Welcome Club, on the lines of Earl's Court and Shepherd's Bush, part of his scheme, whereas the "Cercle Privée" of the Continental casino is merely a nom de guerre. "Nisch" is good, both in composition and plan, with detail of a late and florid Renaissance type, including rococo features permissible in the design for a casino. We should be inclined to give this design a fairly high place in the competition. "Gee Ess Ae" is so similar in parts to the winning design that we should imagine it to be by the same author. It has a very similar dome, but smaller and covering only the entrance salon. We like the flanking towers of this in composition, but the plan is not equal to the successful one, though the design as a whole is good and well drawn. "Rush" is a very fair design, but fails in the central feature, the top of which looks as though it would blow off—not actually as a piece of construction, but from its apparent insufficiency of union with its supports.

Next to the Soane Medallion in importance comes the Pugin Studentship, not perhaps for its actual money value, in which it is surpassed by the Owen Jones Studentship and the Godwin Bursary, but for its prestige. It is delightful to know that although Gothic is absolutely dead for all present-day architectural design save church work, in which Renaissance is no mean competitor, and although there is precious little activity in church building, there are still to be found sufficient earnest students of mediæval architecture to furnish nine competitors for this prize. The work they submit is of a high order throughout, some of it perhaps tending too much to the pretty-picture order of draughtsmanship, and some of the measured work lacking in a wise discrimination of the relative value of subjects. Mr. SYDNEY H. MILLER fairly wins the prize by good measured work in the presbytery bay from Ely and the sedilia at Howton, excellent perspective drawing and a wise proportion between sketches and measured work. Good serious work and capable draughtsmanship mark Mr. MILLER as worthy of a place amongst the Pugin students, though we cannot quite place him in the front rank of that galaxy of talent. Mr. H. HUBERT FRASER would seem to be a friend of Mr. MILLER, for one of his principal contributions is also from Howton, the Easter sepulchre; and a very praiseworthy piece of measured work it is. We like, too, his measured drawings of the porch of Southwold Church, and we are glad he did not leave that charming church without drawing one at least of the figures from the beautiful screen. Mr. FRASER has been honoured by the judges, and in our opinion he has run Mr. MILLER very close for the Studentship. Mr. FRANK HEARNE has sent in too much measured work and too little perspective and freehand sketching. Mr. JOHN L. BERRY and Mr. A. G. BLACKFORD have worked on the right lines, but their draughtsmanship is not good enough to win. Mr. PERCY MAY has contributed some good and pretty sketches, but not enough serious work. Mr. L. McD. GILL has some very fair water-colour sketches of French mediæval architecture, but the subjects he has chosen for his measured work were hardly worth doing in competing for the Pugin Studentship.

The Tite Prize has attracted no less than twenty-one competitors, more than twice as many as any other prize, but we fail to see one that complies entirely with the original intention of "Design according to the Principles of PALLADIO, VIGNOLA, WREN, or CHAMBERS."

The subject, a covered arcade of shops, has evidently proved attractive, and as planning forms no part of the problem, the competitors were free to give their attention to the more obvious part of architectural design.

Mr. R. W. M. GUNN has sent in a remarkably good design, but it is modern French of "le dernier cri," and if the author has not actually worked in a Parisian atelier he has evidently made a close and intelligent study of the latest mode in Paris. His draughtsmanship also shows French influence, though his well-drawn perspective in pencil is superior to what we should expect from a student wholly trained in a French school. The design placed second, which is by Mr. BERTRAM E. LISLE, is far more in accordance with the type of design Sir WILLIAM TITE would have favoured, and if the original founder of the prize had been the assessor, would probably have secured first place. It is severe and restrained in treatment and a thoroughly good design. The design placed third is that of Mr. S. HERBERT MAW, who, by the way, was the Soane Medallist of 1905, and is in that phase of ultra-modern English Renaissance of which Mr. R. FRANK ATKINSON is so able an exponent. This, too, is a really good design, and is illustrated by some very fine drawings, of which the coloured perspective and the detail in shaded

Digitized by Google

Indian ink, with remarkably clever coloured pictures in the panels, are especially noteworthy. Although Mr. MAW has not been successful in winning the prize, he has proved himself a most able draughtsman. "Palladio" has a good interior, but his street front is altogether too wild. It would make the Italian master turn in his grave to find his name associated with such a conception, presumed to be in accordance with his principles.

The competitors for the Grissell Gold Medal have mostly forgotten that this prize is for design and construction, and the winner, Mr. DOUGLAS W. DAY, is practically the only one who has, first, made a decent design; secondly, introduced into it a real constructive problem; and thirdly, adequately grappled with and solved the problem. Mr. DAY'S central feature has a double dome, the construction and stresses in which he has carefully and fully worked out in a very able manner, whilst his design is entirely suitable for the subject set for the prize. "Xopher Gubbins, C.E.," is the only other set of drawings that makes any attempt at the solution of special constructive problems, but is not equal either in this direction or in design to that which has obtained the prize.

The valuable Owen Jones Studentship of 100*l.* has practically gone begging. Mr. MAW, whose name we have already mentioned above, is the only applicant, and although he has sent in some painstaking work from the Scala d'Oro of the Ducal Palace at Venice and the Corsini Chapel in the church of St. John Lateran at Rome, receives only an award of honour of twenty guineas instead of the full Studentship. We know from his drawings for the Tite Prize that Mr. MAW is capable of winning the Studentship, and we should advise him, on the authority of a former unsuccessful competitor, who made the same mistake that he has made, to send in some coloured sketches of work as it is to-day, not merely measured drawings of the work as it was when it was executed. This always looks and is considered hard and unsympathetic, and if Mr. MAW had made, what he is capable of making, coloured perspectives of the Scala and the Chapel, with accidentals of playing light, as well as the measured drawings, we think he would have won. Mosaic especially wants very careful rendering to avoid hardness.

ARCHITECTURE: ITS TRUE PRINCIPLES.—II.

By R. OWEN ALLSOP.

THE ELEMENTS OF DESIGN.

TO study architectural form depleted of all ornamental accessories broadens our conception of the nature of our art. Such study necessarily throws us back on first principles. This is greatly to be desired, inasmuch as to work on principle—under laws—entails restraint. Too often we see unbridled license in design passing muster on the plea of originality. If it is necessary that true design must be novel, we must inquire wherein the opportunity for such novelty best presents itself under the peculiar position of modern architecture. One might at the outset of such inquiry very reasonably ask, "Why novel?" We have had much sighing after a novel style of architecture during past years. The necessity for the new style is not apparent. One might as reasonably desire a new type of human form, sky, and landscape, or complain that there was a wearying sameness in the normal tongue, and that we required all these, and more, made anew as a change. The fact is, and it is doubtless by this time understood, the cry for a new style is misleading and based on false premises.

Now in the novel combination of old forms to produce new scenes we find that there is in nature scope for illimitable variation of effect. We desire no new heavens because the face of such continually varies by rearrangement of components leading to novel aspects of the whole. What time the present-day architect can outdo the efforts of the old architects in their several modes of building, we may have some reasonable excuse for clamouring for a new style of architecture. It seems more nearly true to say that there are too many styles of architecture in the present day. Every originally-minded architect is himself the founder of a new style—good or bad. The bald truth is we are, generally, ignorant of—have never grasped—the true principles of graceful building. At the best the average modern work of architecture is a patchwork—a conglomeration of old forms. Our répertoire of architectural detail is more extensive than heretofore, our minds overburdened with peculiarities of buildings from all parts of the world, what with cheap travelling and the ubiquitous camera. If style details and peculiarities are architecture we have a plethora of such, a plenitude of power undreamt of by the ancient designers. Any defective quality of the architecture of to-day cannot be referred to lack of knowledge, or difficulty in obtaining a knowledge of details of style. Yet in spite of photography and world-wide railway and steamship facilities, we are wearied by superficial miles of hackneyed columns and mouldings and whole groups of architectural device in set proportions.

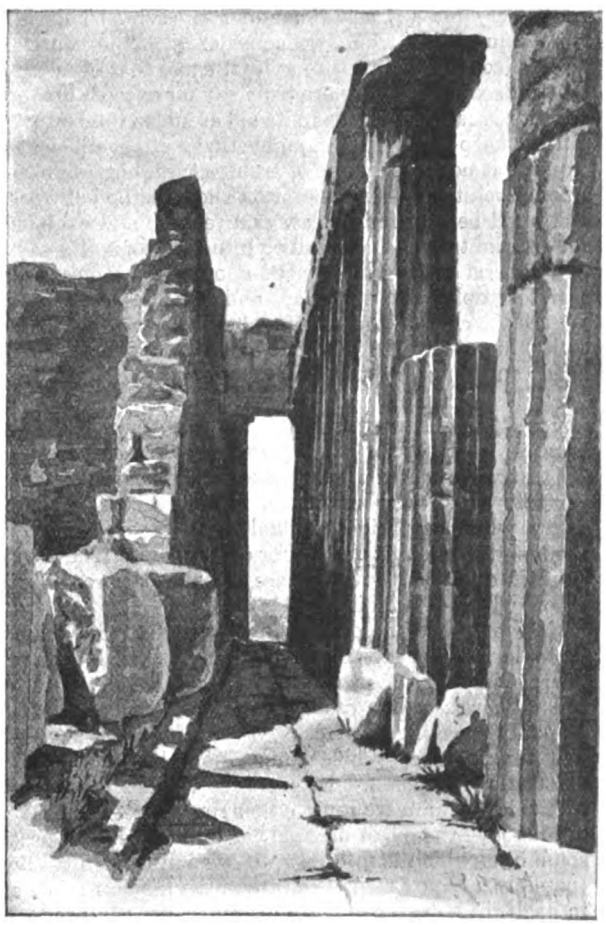

FIG. 6.—IN THE PARTHENON.

We are compilers generally, composers seldom. A harmony in stone geometry was composed years back—we copy *ad nauseam*. What would be thought of our musical composers if they gave us nothing but more or less true excerpts of some old school of music, or of an author if he rendered to us eternally whole set phrases of bygone writers? Yet we never hear of an author or musician complaining of the want of a new style of writing or composition. The reason is doubtless because the true writer and the true musician concentrate on the subject, the theory, the theme, and throw false "style" to the winds.

Yet we, with our boundless storehouse of facts and liberty of action, copy, while they, with their simpler material and rigid methods produce living work. This seems incomprehensible. We have suggested that the root cause of the evil that we all see and deplore is the habit of copying and patching that so largely represents modern

Digitized by Google

architectural design, whereas, as we further suggested, design to be truly such must be novel—the work of reason.

That there is as a rule really little or no such reason may be ascertained by demanding the why and wherefore of every line and form in a composition. In the introspection of science the question asked is "How?" Let the architect rather inquire of himself "Why?" If he can at all times give a logical answer, he is working on principle; if not, the process is at the best rule of thumb. The "principles" employed may have many unsound planks; but the honest effort to work on some base—from data—is commendable.

If now we contrast the work of the musical composer we find that all such are working under strict rule—fundamental truths that cannot possibly be ignored, except perhaps momentarily, as in a designed discord. All novel compositions of the musician are necessarily based on law, which, while preventing the production of an abortion, do not stand in the way of variety and the impress of individuality. To the inquiry "Why?" such a designer of sound harmonies has always a ready answer.

We do not know that there has ever been in any other art the cry for a "new" manner or style. This is the more remarkable when we consider that the sources of novel effects in architecture at least equal that of any other art—indeed, we ought more truly say far exceeds any other art—for it calls in all arts to its aid as added interest. We cannot keep back the thought that, after all, what is required is not a new style of architecture, but a new spirit among architects—a regeneration and a method of working that shall be founded on law and reason, and exclude all ape-like imitation. We call to mind NAPOLEON'S saying, "A general always has troops enough if he only knows how to employ those he has, and bivouacs with them." We see clearly that the architect has abundance of material with which to work, if he but looks around him, close at hand, and far afield through the eye of photography.

It is desirable to realise the true significance of the saying, "There is nothing new under the sun." It bids us cease to worry for novelty for its own sake, resting in the assurance that the words are particularly applicable to our art. It warns us of the futility of seeking a new entity, while a sufficient originality can be produced by recombination of old forms. For one apparent true novelty, myriads of virtual novelties are produced by recombining of that which of itself is old.

We may give a concrete illustration. Suppose, for example, that a certain architectural pillar is not to be improved by any effort or study we can devote to its form and features. We must, therefore, accept such as, humanly speaking, perfect. We are far from suggesting that this is a reasonable supposition, but it will do for illustration purposes. In every use, then, made of this particular column we must either reproduce—as by a pair of mirrors—the exact original, or by amendment produce something which is inferior. If we call this an x column (possibly a happy suggestion) then the x column is a style in itself, in however minor a degree. We can produce no novel effect from it except what is inferior to the perfect type itself. But it is at once evident that in dealing with a number of x columns a practically infinite variety is open to us by new spacing, new grouping, both in plan and elevation, and in their combination with other forms. The column is little more than a single note in the harmony and whoever heard of anyone declaring himself weary of a certain pitch of musical sound, if it be the true voice of nature, and not a crack-pot, like Big Ben? From this line of reasoning we quickly perceive that the composer may produce beautiful effects and novel by recombining old entities.

In taking the above line of argument, it would seem necessary to define the meaning of the expression "architectural form." It is unnecessary, for the moment, to do this. It may be noted in passing, however, that in chemical combination no new substance can be formed unless the old is first broken up into its elemental atoms, or at least into molecules. It would be a great gain if we could arrive at some definite understanding as to what constitute the atoms of architecture. Old details certainly do not. These may be practically destroyed and yet architectural effect remain. In the scene in the ruined Parthenon (fig. 6) it cannot be said that any detail is visible. Yet there is effect, and an effect of architecture. It would seem that in Order and Arrangement and Perpendicularity—with its complement, Horizontality—may be discovered the genesis of architectural effect.

(To be continued.)

THE WORKMEN'S COMPENSATION ACT (1906) IN OPERATION.—II.

By W. S. HOLDSWORTH, D.C.L.

Questions Relating to the Amount of Compensation payable.

THE scale and conditions of compensation are contained in the first and second sections of the first schedule to the Act. The various rules for ascertaining the sums payable are not altogether easy to apply in all instances, and several cases have been needed to put an authoritative intepretation upon them. The most important of these cases are a group of four, judgment in which was given together in December 1907.* In the judgments of Cozens-Hardy, M.R., and Fletcher Moulton, L.J., the rules are carefully and lucidly explained.

In one case (schedule 1, section 1 (*a*) (i.)), the compensation payable is based upon the actual wages received by the workman. That is the case where a workman meets with a fatal accident, who has for the three years preceding the accident been in the employment of the same employer. In such a case, if he leaves dependants wholly dependent upon him, he is entitled to a sum equal to the whole of his earnings during the preceding three years, or 150*l*., whichever is the larger, but not exceeding in any case 300*l*. As Fletcher Moulton, L.J., put it, the Legislature seems to have thought that, when there has been three years' uninterrupted employment, the most satisfactory solution of the question of the amount of compensation was to take the facts as they stand, and let the amount be the reproduction of the actual earnings during the three years.

But in all other cases the amount of compensation is based upon average weekly earnings. If a man who has not served the same employer for three years is killed and leaves dependants, the amount of his earnings is to be deemed to be 156 times his average weekly earnings during the period of his employment. If any workman is totally or partially injured he is entitled to a weekly payment not exceeding 50 per cent. of his average weekly earnings during the preceding twelve months if he has been so long employed, or, if not, for any less period during which he has been in the employ of the same employer, such payment not to exceed 1*l*. Section 2 of the schedule then lays down certain rules for the computation of these average weekly earnings. The guiding idea is contained in the first sentence of sub-section (*a*)—"average weekly earnings shall be computed in such manner as is best calculated to give the rate per week at which the workman was being remunerated." † Therefore we cannot simply take the amount per week at which the workman was being paid at the time of the accident. So to do might be unfair in some cases to the employer, in other cases to the workman. We must take into consideration the circumstances prevailing before, as well as at the time of the accident. "The term average weekly earnings signifies broadly the average earnings which the workman would make in a normal week if employed on the terms prevailing before and up to the time of the accident." ‡

It is clear that the question at once arises whether to ascertain an average we are to divide the earnings by the total number of weeks in a given period, or by the total number of weeks in which work was done during that period. The Court of Appeal has clearly held that in the normal case, when the employment is continuous, the divisor must be the number of weeks worked. It might be otherwise when the employment was discontinuous. Thus if a man was employed to assist to do certain jobs on certain days occurring at irregular intervals, and was paid by the day, his average

* Perry *v.* Wright; Cain *v.* Frederick Leyland & Co.; Bailey *v.* Kenworthy, Ltd.; Gough *v.* Crawshay Bros., Cyfarthfa, Ltd., 1908 1 K.B. 441; 24 T. L. R. 166.

† Schedule 1, section 2 (*a*).

‡ 1908 1 K.B. at p. 456, *per* Fletcher Moulton, L.J.

Digitized by Google

weekly earnings would be the sum of his earnings during the period, divided by the total number of weeks in that period. But in the normal case of continuous employment the weeks worked can alone be regarded; thus, if a man earns 2*l.* a week in works which are regularly stopped for holidays two weeks in the year, the yearly wage is represented by 2*l.* multiplied by fifty and not by fifty-two; and the average weekly wage would be 100*l.* divided by fifty-two. In arriving at this average weekly wage it would not be allowable in the case of a particular workman to take into consideration the fact that a larger or smaller amount of these holidays had occurred in the period over which the average was taken. Two workmen in the same employ at the same wage would be entitled to have their average weekly earnings estimated at the same figure, though the fortnight's holiday had occurred during the engagement of the one, and not during the engagement of the other. An illustration of the working of this principle is contained in the case of Bailey *v.* Kenworthy, Ltd. In this case the man was injured, and it became necessary to compute his average weekly earnings during the preceding twelve months. He was continuously employed except in certain holiday seasons, such as Wakes Week, Bank Holidays, &c., amounting to two weeks in the year, and except for interruptions due to accident and other causes amounting to one week in the year. His yearly earnings were 83*l.* 2*s.* 1*d.*, earned in forty-nine weeks of work. That sum divided by forty-nine, gives the average weekly wage in a week of full work. But there are only fifty weeks of full work in the year, not fifty-two, therefore we must deduct from the average weekly wage, ascertained by dividing 83*l.* 2*s.* 1*d.* by forty-nine, one twenty-sixth part. "In other words, the earnings in a week of full work are to that extent higher than the average weekly earnings of the employment, because there is incident to it an enforced idleness of two weeks in the year." *

The schedule (section 2 (*a*)) recognises that, "by reason of the shortness of the time during which the workman has been in the employment of his employer, or by reason of the casual nature of the employment, or the terms of the employment," it may be impracticable at the time of the accident to compute the rate of remuneration. In that case, "regard may be had to the average weekly amount which, during the twelve months previous to the accident, was being earned by a person in the same grade, employed at the same work by the same employer, or, if there is no person so employed, by a person in the same grade employed in the same class of employment and in the same district." The schedule does not contain any definition of the term "grade." Cozens-Hardy, M.R., says, "I think it refers to the particular rank in the industrial hierarchy occupied by the workman, such as shepherd, carter or common labourer on a farm, or mason, bricklayer or bricklayer's labourer in the building trade, and not to his greater or less excellence in that rank." The question whether there is any grade, and the question what is the average weekly wage earned in that grade, is an abstract question of fact to be determined by the Court or the arbitrator, without reference to the merits or demerits of the applicant. When these two points have been settled the Court must then consider the personal merits or demerits of the applicant; and evidence of such matters as his skill or efficiency is relevant to determine whether he is above or below the average. An illustration of the working of this clause is afforded by the case of Perry *v.* Wright. † In that case the applicant was a casual dock labourer. As there was no person "in the same grade employed at the same work by the same employer," the Court was obliged to consider the average wage of "a person in the same grade employed in the same class of employment and in the same district." The County Court Judge had found that there were two grades of casual dock labourers—the good and the bad; that the former earned on an average 30*s.* and the latter 15*s.* a week; and that the applicant fell into the latter class. The Court of Appeal held that this mode of settling the matter was wrong. Casual dock labourers formed one grade—"so that it is an error to talk about a class of good workmen and a class of bad workmen as constituting different grades." The County Court Judge should first have determined the average wage of a man whose grade was that of a casual dock labourer, and then have considered how far he fell below that average.

In sub-section (*c*) of section 2 of the schedule a definition is given of the phrase "employment by the same employer." "Employment by the same employer shall be taken to mean employment by the same employer in the grade in which the workman was employed at the time of the accident, uninterrupted by absence from work due to illness or any other unavoidable cause." This definition, taken in connection with the provisions of sub-section (*a*) cited above, makes it clear, as Fletcher Moulton, L.J., points out, "that in taking the average we are restricted to the period during which the workman has been employed in the same grade."* So that if at the time of the accident he has been promoted to a higher grade or come down to a lower grade, his earnings during the time he was in the lower or the higher grade cannot be regarded. The working of this principle is illustrated by the case of Gough *v.* Crawshay Bros., Cyfarthfa, Ltd. In that case a collier had had a previous accident, and while incapacitated from work had received 15*s.* 8*d.* per week. Having partially recovered he was given light work at certain wages, and the amount of his compensation was reduced each week by half the amount earned in that week. While engaged on this light work he was killed by an accident. It was held that the compensation must be based on his average weekly earnings in his new grade, and that his former earnings as a collier could not be regarded. It was attempted to be argued that the money payable in respect of his first accident should be taken into account. But, as the Court held, such payment had no more to do with the computation of his average weekly wage than if he had been "in receipt of weekly payments left to him by a friend in his will."

It is fairly clear that a man's wage cannot be simply confined to the money received by him. The value of board or lodging or other allowances must be taken into account. Where by the nature of the employment the workman must be provided with such board and lodging by his employer, the measure of their value seems to be the cost of the employer. Thus in the case of Rosengvist *v.* Bowring & Co., Ltd.,† a seaman was paid 21*s.* a week and received board and lodging. It was held that though there might be cases in which the cost of the board and lodging to the employer might not be a fair measure of damages, in this case it clearly was. The sailor must sail on a ship which was provisioned when it started. "It was idle to consider at what cost the sailor could have purchased his salt pork . . . at the first port the vessel touched, or what he could have got it for in the middle of the ocean." ‡ It followed that "in such an employment as this there was no other practical or real test than to say that the measure of the value to the sailor was the cost to the employer." It would seem that much the same reasoning would apply to the case of domestic servants, who must by the nature of the case live in their employer's house. It would not, as this case points out, necessarily apply to a farmer who boards his labourers in his house.

It is not only board and lodging which may be an element in the wage earned. There may be in some cases other allowances sufficiently regular and recognised to be taken into consideration. In the case of Penn *v.* Spiers & Pond, Ltd.,§ it was held that in reckoning the earnings of a deceased waiter the amount of his "tips" could be taken into account. These were earnings "in the employment" in which the man was engaged; and it is notorious that there are many like cases in which an employé's earnings in the employment do not come from the employer. If the receiving of tips is a recognised and notorious incident of the employment, if they are received with the knowledge and sanction of the employer, if they are not merely casual and trivial, their amount must be brought into account in estimating the average weekly wage.

The employer is liable to pay compensation during the incapacity caused to the workman by the accident. In order to ascertain whether or no the incapacity continues, section 14 of schedule 1 provides that a workman receiving weekly payments may be required to submit himself for medical examination by a duly qualified medical practitioner; and section 16 provides that a weekly payment may be reviewed by the Court at the request of either employer or workman. In the case of Nicholson *v.* Piper,‖ decided under the 1897 Act, the schedule to which contains similar provisions, it

Digitized by Google

was held by the House of Lords that an award terminating the weekly payments was final, and therefore that the right to receive compensation could not revive on account of the recurrence of the incapacity. Where such recurrence is feared it is usually the practice for the judge not to terminate the payments, but to suspend them by ordering the payment of a nominal sum. The House of Lords in this case declined to express any opinion as to the legality of this practice.

Neither the Act nor the schedule thereto contain any provision for the case where a workman refuses to take ordinary remedies for ending his incapacity. The case of Warncken *v.* Richard Moreland & Son, Ltd.,* lays down a clear rule on this point. If the workman refuses to adopt a remedy, such as a surgical operation, which involves no appreciable risk, he cannot continue to claim full compensation. As Cozens-Hardy, M.R., said, in such a case it might be said that the workman's continued incapacity arose, not from the accident, but from refusal to take reasonable means to get rid of its consequences. It is clear, as was laid down in the earlier case of Rothwell *v.* Davies,† that this reasoning does not apply if the operation is attended with risk.

(*To be continued.*)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last at Conduit Street, W., Mr. Ernest George, president, in the chair.

Mr. R. STEPHEN AYLING read a paper entitled

Public Abattoirs.

From a humanitarian point of view, he said, it is our bounden duty to animals that they should be killed as painlessly and under the best conditions possible; it is a duty to ourselves that meat supplied for human consumption should be free from disease, that those places in which the work of slaughtering and dressing meat foods take place should be as hygienically perfect as possible, and it is an important matter of policy that by-products and other valuable materials should be utilised to their fullest extent. These essentials can only be achieved by the establishment of public abattoirs throughout the country, and by the elimination of private slaughter-houses.

When the public abattoir system is established as firmly here as it is to-day on the Continent, there will be a very wide field open for the English architect to design these utilitarian but certainly complex buildings, well planned and with a distinctive character.

In England and Wales to-day we have nominally about ninety-eight public abattoirs, but nearly two-thirds of the buildings are very small, or obsolete in planning; in fact, a large number cannot be really seriously considered as public abattoirs at all. Even if they were all satisfactory this number would represent one institution to about every 330,000 inhabitants. As a matter of comparison, taking one-third of the existing abattoirs as being reasonably representative buildings, we have to-day in England and Wales one public abattoir to each million of the population. It is therefore apparent that we have hardly reached the fringe of an "abattoir system." In Paris to-day there are two splendid municipal abattoirs, supplying the meat for the whole of the city, and not a single private slaughter-house. In London alone to-day we have about 294 private slaughter-houses and not a single municipal one.

The paper gave the disposition of the private slaughter-houses licensed last year by the London County Council, in the area covered by the map published in the London Directory. There are 222 private slaughter-houses in that area, and in nearly every case they are in the midst of residential property. The fact that they should exist at all, many in populous districts and surrounded by houses, is an offence to humanity, hygiene and economy. We pride ourselves on the enormous strides we have made in sanitary science during the last fifty years, but on this particular subject we are at least a century behind our Continental neighbours. Recently plans have been prepared for a public abattoir in Constantinople, and the work either has been or shortly will be commenced. When this has been accomplished, London will stand in "splendid" isolation by being the only European capital without such an institution.

The author enumerated the many defects inseparable from the system of scattered private slaughter-houses, and showed how they can be, and are, prevented in the public abattoir. Almost invariably on the Continent (and sometimes in England) these buildings are erected in the suburbs, and in close proximity to a railway, so that the necessity for driving animals through the streets does not exist. Diseased meat sold for food is practically unknown owing to the employment of fully qualified veterinary inspectors, who are continually on the spot while animals are being killed. Wanton cruelty is reduced to a minimum, as the municipal buildings are under the fierce light of publicity, the officials are continuously in attendance, and only trained men are engaged as slaughterers.

Having dealt with the question of finance, and given statistics to show that public abattoirs can be made self-supporting or even profitable, the author set out the salient points to be observed in a well-planned abattoir. The existing buildings of this kind can be, broadly, divided into two classes, those on the "block system," where all the main departments are under one roof, and the "separate system," where the main buildings are separated by roads or passages. The main buildings of a moderately-sized abattoir consist of lairs for various animals, slaughter-hall, cooling-room, administrative block, superintendent's house, cold stores and chill-rooms, destructor, buildings for the preparation of by-products and offal, workmen's mess-rooms, kitchen, bath, &c., and pathological room.

The author described the magnificent cattle market and abattoir of La Villette, Paris, designed by M. Janvier, and opened in 1867, and showed illustrations of the various markets, buildings, and slaughter-courts. The area is 105 acres, and about 2,500,000 animals are killed there per annum.

Illustrations were shown also of three typical German abattoirs, viz., those of Berlin, Leipzig and Offenbach. Some of the Continental abattoirs are among the finest buildings erected. While Birmingham spends nearly 5*s.* a head for its abattoir, the little town of Offenbach in Germany, for instance, has spent 1*l.* 13*s.* 7*d.* per head of its 60,000 inhabitants.

Turning to English abattoirs, the author considered the plan of the abattoir at the Dockyard, Chatham, most perfect, not only from the humanitarian point of view, but as regards facilities for working. The plan is the outcome of a report of the Commission appointed by the Admiralty to inquire into the question of the "humane slaughtering of animals," and the many witnesses examined were all experts engaged in those trades and professions appertaining to the subject. The main points in the report were as follows:—"That animals awaiting slaughter should be spared any contact with the signs or smell of the slaughter-house; that waiting-pens should be separated from the slaughter-chamber by sliding doors; that floors should be impervious and not slippery; that cattle should be slaughtered screened off from their fellows; that immediately the carcases have been bled they should be dressed in an adjoining chamber, screened off from view of animals entering the slaughter-house." These recommendations have been admirably carried out at Chatham. The buildings were designed in the Admiralty Office under the superintendence of Mr. J. Brookes Hunt.

Plans, elevations, and in some cases photographs of a number of public abattoirs in England, including a unique plan suggested by the Model Abattoir Society were exhibited, and points of interest called attention to.

In Scotland to-day, out of 206 burghs, 124 of them, or nearly 61 per cent., have public abattoirs and greatly added powers for closing the private slaughter-houses. The Local Government Board of Scotland is now advocating the erection of public abattoirs in or near all towns. A radius of five miles is suggested for towns with from 6,000 to 8,000 inhabitants. Scotland is much in advance of England, and is gradually approaching an "abattoir system."

As regards materials, in the erection of these buildings wood should be used only where absolutely necessary. Stability and facilities for scrupulous cleanliness must be the keynote. The floors must be of perfectly impervious material, and white glazed brickwork or tiles largely used in the interior of the buildings, so that every trace of dirt or blood may be easily detected and removed. Throughout the buildings very light paint—preferably white—should be employed.

The question for or against public abattoirs appears to the author to be a national rather than a political one. He was strongly of opinion that a general "abattoir system" would encourage the British farmer to raise home-grown

* 25 T. L. R. 129. † 19 T. L. R. 423.

Digitized by Google

cattle, which would not only be to his pecuniary advantage, but also benefit the British consumer.

To trade opposition and vested interests the author attributed the fact that public abattoirs have not superseded private slaughter-houses in this country. Trade opposition is very strongly against the abattoir system, as under it inspection of meat would naturally be more stringent than is possible at the present time, so that diseased meat food would be condemned in a much greater proportion.

In some concluding remarks reference was made to the question of "official architecture" in connection with the subject. Abattoir buildings complying with various requirements, complex engineering work, elaborate sanitary work, considerations of humanity in stabling and slaughtering, the most efficient methods of veterinary inspection, &c., all tend to render them practically impossible to be designed by a single individual, however talented. In any large abattoir scheme the architect, engineers (constructional and municipal), medical officer of health, and veterinary surgeon should work together harmoniously.

Mr. SYDNEY PERKS said what he wished to say was more in the nature of a protest than anything else. The lecturer had carefully considered many buildings and model plans, but an inspection of the illustrations round the walls of the room did not reveal his own name among those of the architects and engineers who had made the original drawings. Mr. Ayling's name was not to be found on one single plan, and the speaker suggested that some model scheme might have been drawn up for the paper. He protested against the statement that in London alone there were about 294 private slaughter-houses, and not a single municipal one. If Mr. Ayling meant by that that there was not a single municipal slaughter-house put up out of the rates he was perhaps right, but there were very large slaughter-houses erected by the Corporation of London on which something like between 30,000*l.* and 40,000*l.* had been spent. Those buildings were at Islington, and when the erection of them was under consideration an expert committee travelled over England and Germany in order to ascertain the best and most suitable plan to be adopted. They were public slaughter-houses in every sense and under the supervision of a fully qualified veterinary surgeon and staff of assistants. The buildings at Islington were so well arranged and equipped that they had been credited to be far in advance of anything to be seen on the Continent. There was certainly not much ornament about them; in fact, the exterior might be described as hideously ugly, but inside the arrangements were perfect. He did not think it was right therefore to allow the statement to go unchallenged that London was doing nothing towards the establishment of public abattoirs. The buildings he mentioned had been erected regardless of expense and with great thought after visiting other slaughter-houses.

Mr. M. HORSFIELD proposed a vote of thanks, and said the paper appealed to him as one who had been through the Chicago stockyards and remembered with regret what he had observed there. In the subject of the paper there was little to attract them as architects, but he thought they must not disdain to do what they could to help in making abattoirs worthy of modern civilisation if the old slaughter-houses were to be replaced.

Mr. J. COULSON NICOL seconded the motion. He had had occasion to visit some slaughter-houses on the Continent, and quite agreed with Mr. Perks's reason for protesting against parts of the paper. Still the author had given them a great deal of information which was difficult to obtain. He was astonished that more reference was not made to the modern slaughter-houses erected in the provinces. Birmingham contained at least one good example. The French plan, covering a wide area and centrally placed, had many advantages, but it could not be applied either to London or the provinces, where land in the centre of the towns was too valuable to be devoted to such buildings. In the provinces there seemed to be a great desire for having public slaughter-houses close to the market-places, and those that had been erected yielded a profitable return. A continuous roof to all slaughter-houses, he thought, was the best plan to be advocated in England. The fittings in such buildings, he believed, were of greater importance than the architecture.

The vote of thanks was carried by acclamation.

DEED OF AWARD OF PRIZES AND STUDENTSHIPS FOR 1908-9.

The Institute Silver Medal and 25 *Guineas.* (Essays.) Subject:—"The Influence on Architecture of Modern Methods of Construction," Mr. Henry H. Hill, B.A., 10 Kildare Gardens, Bayswater, London; hon. mention, Mr. Horace Cubitt, 227-8 Strand, London, and Mr. J. Maclaren Ross, 11 Great James Street, Bedford Row, London.

The Institute Silver Medal and 10 *Guineas.* (Drawings.) Subject:—"Measured Drawings of Ancient Buildings in the United Kingdom or Abroad," Mr. Ernest W. Wray, 28 Scott Street, York; hon. mention, Mr. Alan G. Brace, Lapworth, Warwick.

The Soane Medallion and 100*l.* Subject:—"Design for a Casino on the Borders of a Lake," Mr. Anthony R. Barker, Sutherlands, Harrow; hon. mention and 20 guineas, Mr. Adrian Berrington, 37 Great Ormond Street, London.

Owen Jones Studentship. The prize withheld. Mr. S. Herbert Maw, The Beeches, Cottingham Road, Hull, awarded 20 guineas.

Pugin Studentship, Silver Medal and 40*l.* Mr. Sydney H. Miller; hon. mention, Mr. H. Hubert Fraser.

The Tite Prize. Subject:—"Design (according to the Principles of Palladio, Vignola, Wren, or Chambers) for a covered Arcade of Shops," Mr. R. W. M. Gunn, 2 Windsor Terrace, Glasgow; prize of 15 guineas, Mr. Bertram E. Lisle, 43 Devereux Road, Wandsworth, London; prize of 10 guineas, Mr. S. Herbert Maw, The Beeches, Cottingham Road, Hull.

The Arthur Cates Prize, 40 *Guineas.*—Mr. Leslie Wilkinson.

The Grissell Gold Medal and 10 *Guineas* (for design and construction). Subject:—"Design for a Landing Stage to a Royal Palace from a Lake," Mr. Douglas W. Day, Deanhurst, Knighton Drive, Leicester.

Godwin Bursary, Silver Medal and 65*l.*—Mr. J. A. Allan.

Ashpitel Prizeman.—Mr. Horace J. Ash, Nuneaton.

A Service will be held early in June next at the Church of the Holy Cross, Crediton, in commemoration of the millenary of the consecration of the first bishop of the ancient see of Crediton. The bishop, Eadulf, was consecrated in 909, with six other bishops, at Canterbury Cathedral by Archbishop Plegmund. The actual date of the consecration is not ascertainable. Crediton Church was a cathedral church from 909 to 1050, when, on the removal of the see to Exeter, it became a collegiate church.

The Council of the Concrete Institute held a meeting last week, at which Sir Henry Tanner presided. It was decided that all new members resident in Great Britain joining after the enrolment of the first 500 members should be subject to an annual subscription of two guineas instead of the present subscription of one guinea, which latter subscription will, however, still be retained for new colonial and foreign members. The membership of the Institute already exceeds 400. A number of appointments to the standing committees of the Institute have now been made. The committee on science, on Parliamentary matters, on mass concrete, and on tests have respectively as chairman Mr. William Dunn, Mr. A. Ross, Mr. C. H. Colson and Mr. W. T. Hatch, and the following are acting as honorary secretaries to various standing committees:—Mr. F. E. Wentworth Shields (science), Mr. J. E. Franck (Parliamentary), Mr. G. Kirkaldy (tests), and Mr. R. W. Vawdrey (reinforced concrete practice). The third general meeting of the Institute will take place at the Royal United Service Institution, Whitehall, on February 18, when Mr. L. Serraillier will read a paper on certain aspects of reinforced concrete.

At the Monthly Meeting of the Sheffield Society of Architects and Surveyors held at the University last week, a paper was contributed by Mr. J. R. Wigfull describing a visit paid to Rouen, Caudebec and St. Wandrille. The president of the society, Councillor W. C. Fenton, presided. Mr. Wigfull gave a graphic description of the magnificent cathedral at Rouen, and the various parish churches of the city, including those of St. Ouen and St. Maclou. Afterwards he dealt with the picturesque little town of Caudebec, where there is a fine church of the fifteenth century, containing a tablet to the master mason, who for thirty years directed the work. The church and the quaint streets of the town were spoken of, and, in conclusion, Mr. Wigfull dealt with the abbey of St. Wandrille, mentioning its connection in early times with the churches of Sheffield and Ecclesfield. The great tithes of Sheffield went to the monks of St. Wandrille, and Ecclesfield was a priory of the abbey until the time of Richard II., when the alien priories were confiscated. The lecture was illustrated by slides made from photographs taken by Mr. Wigfull.

NOTES AND COMMENTS.

AT the Annual Convention of the American Institute of Architects held at Washington on December 15, 16 and 17 last were considered several matters of more than local interest. Of these the first, and perhaps we may say the most important, as it concerns the Art of Architecture rather than the profession of architects, was the organisation of a Bureau of Fine Arts as a Government department. In this country we have been occasionally, and more particularly of late, favoured in the daily Press with the vague and inchoate contention that some body should be constituted to regulate the architectural design of buildings in our chief cities, and particularly in London. Whether it is desirable to regulate the design of our street architecture, and, if so, in what direction and to what extent, is a matter open to discussion and permitting of a great variety of opinion, seeing that we here pride ourselves, and perhaps justifiably, upon the infinite variety of our architectural treatment in the latter nineteenth and early twentieth century. This, however, does not preclude the establishment of a Bureau of Fine Arts, and Senator NEWLANDS, of Nevada, in his address to the Convention of American Architects, rightly emphasised the economic and the commercial value of art. If this be so in a country necessarily mainly self-contained, such as is the United States, still more so is it in our own.

WHAT Senator NEWLANDS said of the American House of Congress is equally true of our own House of Commons. "Congress rarely leads in public opinion; you may say it never leads in public opinion." "Congress simply records public opinion in the statutes." He therefore, as a practical and experienced legislator, gave sound advice to the American architects as to how they must organise and educate public opinion if they wished for any action on the part of Congress. And we over here might well learn the lesson that he taught.

THE establishment of a Bureau of Fine Arts in this country would, if properly constituted and subsidised, be of incalculable advantage not only to architecture but to art generally. First, however, the public has to be educated to recognise that art is not a useless and expensive luxury, but a national asset of economic and commercial value.

THE latest news is that President ROOSEVELT has consented to appoint an Advisory Council on Fine Arts, to assist the Government on all questions of public works in which art plays a part.

THE next subject of interest was that of professional charges, and the American Institute of Architects resolved to raise the minimum remuneration which they would regard as the standard to 6 per cent. instead of 5 per cent. hitherto recognised, the reason for this being the increased responsibilities of the architect and the greater skill and efficiency now required from him as compared with those of the time when the 5 per cent. basis was established. Amongst the many matters in the affairs of the Royal Institute of British Architects requiring readjustment on the reception of the new charter is that of the schedule of charges, and the line taken by our transatlantic confrères is worthy of consideration in this connection, for here as there both the responsibilities and the requisite knowledge of a modern architect have enormously increased during the last half-century.

THE third matter of interest is expressed in the resolution, "That it is the sense of the Convention that the various chapters should prepare codes of ethics, as these may be determined by local conditions, submitting these codes to the Board of Directors of the American Institute of Architects for criticism, and to aid it in preparing a general code." This, translated into English, is analogous to a request that the Allied Societies should express their views on questions of professional etiquette and transmit them to the Council of the Royal Institute for that body to prepare a code. It is high time that such a step was taken here, for the present position is simply ludicrous. A professional member of the Royal Institute signs a declaration that he will not accept illicit commissions, a thing he is forbidden to do by the statutes of the realm. He is told that it is bad form to put his name on a board to announce that he is architect of a building in course of erection, but that he may put it on the building when it is finished, a thing he is bound to do by the law of the land if he desires to reap its full advantage. He is also told that he must not style himself otherwise than "architect" or "architect and surveyor," which, taken literally, precludes him—and many members seem to read the prohibition thus and act up to it—from using the letters F.R.I.B.A. or A.R.I.B.A. after his name, a thing he is empowered to do by the Charter!

THESE puerile restrictions constitute all the guidance that the Royal Institute gives its members on the many debatable or questionable practices that are or may be adopted by some architects, and as to which many a well-meaning practitioner finds himself unable to decide the right course. We sadly need here a code of professional etiquette, or, we prefer the American term, ethics. We believe the Practice Standing Committee of the Royal Institute are considering the question of professional advertising, but they are a terribly long time over it.

ILLUSTRATIONS.

ST. LUKE'S CHURCH, EDINBURGH.—EXTERIOR—INTERIOR.

THIS new church has been erected on a splendid site in East Fettes Avenue, Edinburgh West, from the designs of Mr. P. MACGREGOR CHALMERS, architect, Glasgow. It is designed in the Norman style, and is finished in stone internally as well as externally. The principal stone is taken from Dullatur quarry, the rubble is from Hailles quarry. There are three aisles, divided by arcades of stone pillars and arches. The design of the arcades has been modelled on the Norman work at Jedburgh Abbey and its prototype at Romsey Abbey. The communion table is placed in a large semicircular apse decorated with arcading and vaulted with stone ribs and concrete panels prepared for mosaic decoration. A smaller apse is provided at the end of the chapel for the font. The choir and organ occupy a small transept. All the furniture of the church is of Austrian oak specially designed by the architect. An interesting feature of the interior is the great variety of the sculpture decoration. No two capitals are carved alike, and the corbels supporting the ribs of the apse vault are carved with scenes from the Life of CHRIST, from the Annunciation to the Ascension. The accompanying plan shows the vestries and halls adjoining. The church accommodates about 950 persons, and has cost about 7,000*l*.

HOLBORN TOWN HALL.—PORTION OF FRONT ELEVATION—THE COURT-ROOM.

WE give two further illustrations this week of these additions, which have been erected at the junction of High Holborn and Broad Street. The Court-room is on the first floor, and will be used for licensing, rating, and other business. Convenient inquiry and waiting rooms are provided. The new buildings correspond in their elevations with the adjoining Holborn Public Library. In our previous issue we showed the principal entrance and the council chamber. The architects are Messrs. WARWICK & HALL, of 13 South Square, Gray's Inn, W.C., whose design was chosen after a limited competition.

ROYAL ACADEMY LECTURES—PAINTING.

THE fourth and last lecture of the course given by Sir Hubert von Herkomer before the students of the Royal Academy was delivered on January 14, and was entitled "Some Personal Experiences." He said that he must confess that he long had a desire to give a lecture on purely autobiographical lines and to tell of experiences in his own career. He was only held back by the thought that it would be a serious violation of tradition. He knew that he was courting danger, as it is considered extremely bad taste to talk of oneself and one's own work. Moreover, it would create a bad precedent. But it had been a very disagreeable effort in preparing those lectures to always be asking oneself if the artist to whom reference might be advantageously made was dead yet. If they inquired of a living artist, "What were the circumstances that led you to start in the style that made your name?" they would get a serviceable answer. The successful artist built his bridges in his early years. The non-successful artist either failed to do so, or built them badly. It should be useful to the student to hear how the successful worker had built his bridges, of what material, and at what period in his life. And no man could tell them this better than the builder himself.

Most artists at the opening of their career had been obsessed by some particular master, whom they had gradually, and sometimes even suddenly, dropped. There were few more interesting studies than such a revolt. Again, most artists when they talk together take delight in hearing personal experiences and exchanging notes about their difficulties. The artistic temperament is rarely secretive. The secretive man will not talk of his difficulties because it is bad form, and also because it is bad business. But what a paltry thing was such a holding back!

In former days the student naturally drifted into the manner of the master in whose studio he was working, not from a desire of flattering, but because he had to do so, or his work would not have harmonised. There was a great difference between imitation that was the result of an obsession and imitation that was the result of a deliberate apprenticeship. The merest accident will often establish an obsession, but it needs far more to get rid of it. An influence could enter a young artist's nature by an unconscious self-inoculation, and not from personal pressure. He himself had been obsessed by Walker's art while he was still a student at Kensington. One contributory cause probably was that Walker's art struck a new note. It never occurred to him (Sir Hubert) to try and create an art that belonged to his own self. He fostered that type until he could or would look at no other painter's work, ancient or modern. Yet he never spoke to Walker in his life. Needless to say, he might have fallen under the spell of a far less satisfactory artist. But he could see most clearly now how the obsession of Walker's art had kept him back from the discovery of his own identity, and had disadvantages in no way commensurate with what he had gained. But youthful enthusiasm must always come before prudence. He at that time considered that the very defects of Walker had to be imitated at all hazards. The works of Titian, Rembrandt, and the other great masters were literally non-existent to him. But the obsession conferred the inestimable boon of making him look for truth in sentiment, and insist on sentiment in truth.

At the age of fourteen he was allowed to join the Southampton School of Art, where he fell under the influence of a student who attended evening classes. At that time he himself had read no art books, for his parents were too poor to buy them. But his fellow-student spent every penny he could get in purchasing such works, and, what was more important, he read them. Sir Hubert listened to him as if he were a god. More than half he could not understand (especially when he came to Ruskin's "Modern Painters"), but he thought it all wonderful, and drank eagerly at the fountain. His fellow-student showed him the landscapes he had painted. The shadows were purple. On his remarking on the extraordinary colours, he was told that Ruskin considered purple a healthy colour. That settled the question. Henceforth all his own shadows were to be purple. He was stricken with purpleitis. Seeing seventeen years afterwards a picture that he had painted while under that influence, he felt so mad with it that he asked the owner to allow him to exchange it for one that he had just finished and which he thought a good one. He brought the picture home, cut out one head for which a relative had sat, and then with infinite relish burnt the rest. Walker's art still influenced him when he came to the South Kensington schools, which were divided into two camps on the question It was pleasant in after years to let memory linger on the untrammelled enthusiasm of early days, but probably such students did not exist nowadays. In those days his iron will did him a bad turn.

The Walker influence was strong upon him when, in 1871, he visited the Bavarian Alps and prepared to paint his first Academy picture, *After the Toil of the Day*. On the day of his arrival with his father he was too impetuous to wait in the inn until the mists had rolled away from the mountains, and at once set out to explore. As he was walking down the village street a rift in the mist revealed the uppermost peak aglow with the rays of the setting sun—nothing but the peak, the rest being shrouded in vapour. It was a glory framed in grey with nothing to suggest its possible connection with the world. Next day when the peak was deprived of its mystery he felt the pain of his first disillusionment. In 1873 his first contribution to the Academy was hung on the line. At a glance many people took the picture for a Walker, so closely did he follow him.

He then resolved to make a large painting in oils of a picture he had drawn some years before for the *Graphic*—*Chelsea Pensioners in Church*. His friends declared that no painter could make anything of the mass of red coats, and that the public were not interested in old men. But such opposition rather strengthened his resolution. Probably no picture on an important scale ever proceeded in such a crazy and haphazard way. At Christmas 1874 the canvas had not been stretched, but he was determined that come what might it would be finished in time for the Academy. He had built a sort of studio in the back garden of his Chelsea lodgings, which measured 24 feet by 8 feet. Here he was handicapped by a near light; so near was it that once, when he was raising the picture up the easel in order to paint the boots of the men, the corner crashed through the skylight and sent a shower of glass on his head. All the architectural background had to be done with the help of a water-colour sketch, for he was not allowed to work on his canvas inside the chapel. He had to guess at the relative distances of the men as they sat in rows. The perspective of the black and white pavement slabs was likewise only arrived at by experiment. Towards the end of February it was still far from finished. By that time he found he could scarcely stand at his work, and a perpetual drowsy feeling came over him which he knew to be the forerunner of a breakdown. He was a total abstainer, and would not have recourse to stimulants. The picture must at all hazards be finished for that year's Academy—but how? Someone told him that he needed exercise; he had neither the time nor the strength for that. However, it struck him that there was something in the remark, and he luckily heard of a machine invented by an American that was said to have saved many overworked brains. It was called the "Health Lift." Some levers and two handles were arranged with a device which registered the precise weight one was lifting when pulling. He used it in every pause in his work. In eight days he felt a marked improvement, and in three weeks he was quite cured and able to lift 900 lb. The time was so short in which he had to complete his work that he unconsciously threw off the Walker influence. But when it was finished he hated it for that very reason. Shortly after sending it to the Academy he received letters of warm congratulation from Lord Leighton and Mr. George Richmond. The former, though unknown to him, gave kindly criticism; while the latter said that when the picture came before the selection committee they clapped their hands enthusiastically. Congratulations were showered down on him from every side. Three years later it obtained even greater success. At the International Exhibition of 1878 in Paris the jury awarded it the first of the ten gold medals of honour that were given to art. His name stood first on the list, having received more votes than any other painter, English or foreign. At the distribution of medals to the representatives of the different countries he and Millais received the two awarded to England. The *Last Muster* was exhibited at many exhibitions all over the world, and everywhere met with the greatest success. It was bought before it was sent to the Academy by the same person who had purchased his first work. The picture belonged to genre painting.

In 1882 he exhibited his portrait, *Archibald Forbes*, which met with considerable success. For the next two or three years he was chiefly represented by portraits of men who more or less resembled the massive war correspondent. Then it got noised abroad somehow that "Herkomer could not paint women." This was somewhat absurd, because no one had ever seen him try. However it had the effect of making him determine to do so. He chose as his sitter

Miss Katherine Grant, who was English and not an American as had been often said, with whose type of beauty he was much in sympathy. However, he found that on a dark background her face seemed somewhat insipid. One day he chanced to put a light canvas behind her head. The effect was such that he determined to so represent her in the portrait. The novelty of it created something of a sensation both in this country and on the Continent. On one occasion when he was in Munich he was discussing a programme for the day with a guide to whom he was quite unknown. The guide said that he must see the portrait painted by an Englishman. They went to the gallery shortly after it was opened, and found that in front of the picture were grouped a lot of chairs for the use of the people who would be discussing it. On the merits of that portrait he still received commissions for other portraits in Germany.

In conclusion, Sir Hubert said it was a very daring thing he had done in lecturing on his personal experiences, but he begged that he would be absolved from any breach of good taste. The storm and stress of his life had enabled him to differentiate between self-laudation and a statement of facts, and it was only a statement of facts that he had given them.

MATERIALS.*

(*Concluded from last week.*)

BRICKS are made of burnt or baked argillaceous or clayey earth, and the quality of the bricks depends upon (*a*) the chemical properties of the earth; (*b*) the preparation of the earth; and (*c*) the different degrees of burning or baking.

The following is approximately the chemical composition of a good brick earth:—Silica, ⅔ths; alumina, ⅛th; free lime, magnesia, manganese, soda and potash, ⅛th. Clay or silicate of alumina forms the bulk of brick earths. It possesses the property of plasticity when damp, but upon the application of sufficient heat it gives off its water, losing its plasticity and becoming permanently rigid; by no known process can its plasticity be restored. It contracts and warps during burning. Silica is present either chemically combined with alumina and water, or free in the form of flint and sand. Its presence in clays produces hardness, resistance to heat, durability, and it prevents shrinkage and warping. According to Dr. Rideal, refractory fire-clays are of two classes:—(1) The silicate of alumina class, in which the alumina is about half the silicate, and the silica mostly in combined form; (2) the silicious class in which silica predominates up to about 90 per cent., mostly in the free state, and the alumina is low.

Lime, when present in brick earths, acts chemically on burning as a flux, causing the particles of the bricks to unite, producing greater molecular strength, and in small quantities diminishing contraction. An excess of lime causes the bricks in burning to melt and lose their shape.

Magnesia and iron influence the colour of bricks. Clays often contain various salts, and those containing a quantity of common salt when it is in excess acts as a flux, causing the bricks to warp and twist, in addition to which such bricks absorb atmospheric moisture for a considerable time.

Very few brick earths are found in such a condition as to allow of their being used without some special preparation. They are practically classed as plastic or strong clays, loamy clays, and marly clays.

Plastic clays contain silica and alumina, but very little lime, magnesia, soda or other salts, and are known as pure clays. For the manufacture of bricks these clays require the addition of silica and lime.

Loamy or mild clays contain quantities of free silica, and are known as sandy clays. To these lime is frequently added. Marls or calcareous clays contain a large proportion of lime, make good bricks, and are frequently used without the addition of other substances.

The treatment of brick earths may be performed by hand or machine, and is:—1st, the preparation of the brick earth; 2nd, the moulding; 3rd, the drying; 4th, the burning.

The chief methods of brick-making are (1) hand-moulded clump-burnt bricks, commonly called stocks; (2) the machine-made wire-cut kiln-burnt; (3) machine-made pressed or hand-moulded kiln-burnt bricks. The ordinary process of brick making is so well known I will not describe it, but Messrs. Eastwood & Co. have recently set up a process for making what are known as slop bricks by machinery, which may be of interest.

The brick earth, which is a thin superficial layer of natural clay, is dug and mixed with water until the mixture is of the consistency of cream; it is then run down iron pipes a distance of more than a mile, and is run into set-backs or shallow tanks formed in the ground, where it is mixed with the ashes or fuel with which it is burnt. After remaining there until the moisture is the consistency of dough, it is conveyed to a machine, in which it is forced into a mould the shape of a brick only larger, to allow for shrinkage. (The clay generally shrinks about one-tenth in all directions.) From this machine the brick is placed in an iron trolley and run into a kiln, which is 180 feet long, and by means of machinery the trolley passes slowly through the kiln; in twenty-four hours coming out at the other end of the kiln dried, and cool enough to handle. It is placed on a second iron trolley and enters another kiln, 180 feet long, in which the brick is raised to a red heat, and slowly allowed to cool as it passes in twenty-four hours to the other end of the kiln, when it is again cool enough to handle, and is taken and stacked ready to be carried away. This process does in forty-eight hours what takes by air-drying under hacks and burning in clamps four months, and the percentage of waste in the first case is not more than 3 per cent., and in the clamp-burnt bricks 25 per cent. to 30 per cent. Machine-made bricks on the Fletton system:—The operation consists in clay-getting, drying, grinding, sifting, pressing and burning. The clay, which is obtained from the Oxford clay formation and is a dense bluish-grey shale, is dug, dried on a drying-floor to expel superfluous moisture, and ground in a mill similar to a mortar mill, the receiver revolving and carrying the clay under the rollers. The bottom of the receiver is perforated, which allows the material when sufficiently ground to fall through as a coarse powder into a pit beneath. It is then elevated and shot into a revolving circular sieve; the material that is sufficiently fine passes through, the remainder is conveyed back to the grinding mill. The sifted powder falls into a hopper, from whence it is passed to the pressing machine, where by an ingenious arrangement it is measured off and passed under the die, when it is pressed into the form of a brick and removed automatically from the mould. The bricks are then placed on barrows, and slacked in the kiln, which is of the Hoffmann type, and then burnt. The time from digging the clay to the slacking in the kiln need not occupy more than fifteen minutes; the time taken to burn the bricks usually occupies about three weeks. Bricks made by this process are being sold in the brickfields at 9*s.* per 1,000, though it is said that they cost 12*s.* 6*d.* per 1,000 to make. The danger of the process is that the Oxford clays contain many fossils, such as ammonites, billimites, &c., and the men who dig the clay are paid 1*s.* 6*d.* per bushel to pick out the fossils; those that are not thus taken out pass into the mill and are ground up with the clay, and on burning are made into free lime. When bricks containing these small particles of lime are built in walls the moisture from the mortar slacks the lime, and it expands and blows the bricks to pieces.

Sand-faced bricks are of a beautiful red colour and texture, often made by hand and pressed by machinery; they are kiln-burnt, and in selecting them great care has to be taken to see that they are sufficiently burnt; the rough test is to sound them—the well-burnt ones have a ring, while the slack-burnt ones sound dull.

Rubbers are similar bricks only always hand-made and of a uniform colour and texture throughout; they can be moulded by cutting with a steel-twisted wire saw and filing; also they can be carved. They are made red and white, but the red ones are the more satisfactory.

Pressed bricks as a rule are made from stiff plastic clay, if white from gault; the red colour is due to oxide of iron, the white to lime, usually in the form of chalk. A new form of white brick is now being made by mixing lime and white sand and pressing the mixture in a mould; they are known as Acme bricks.

Glazed bricks are usually made from stoneware clays, and are either salt-glazed—that is, salt is thrown into the kiln to produce the glaze—or are dipped in a slip of specially prepared clay when half-burnt, which produces a smooth china face.

The various forms of paving-tiles are made of stoneware pressed in moulds, and either coloured by various oxides, or the tiles are what is called enamelled or glazed when they are dipped in slip exactly like the glazed bricks. Encaustic tiles have a pattern sunk in them in which various slips are placed, and when fired these change to permanent colours;

* A paper by Mr. H. D. Searles-Wood, read at the meeting of the Architectural Association on January 8.

and beautiful examples are to be seen, especially in old Spanish buildings.

Of late years glass tiles have been largely used for wall surfaces and there are many varieties on the market; the only difference in them consists in the method of preparing the backing by which they adhere to the cement which secures them to the wall, the great difficulty being to overcome the difference of expansion between the glass and the wall in varying temperatures. If this is not overcome the glass cracks and comes away from the wall, and many unfortunate examples can be seen in London; on the other hand, the Central London Railway stations are splendid examples of this class of work.

The science committee of the Royal Institute of British Architects carried out some experiments on the strength of brickwork, and the results, which have been given from time to time in papers read at the Royal Institute, have now been collected in book form and can be obtained at the Institute. The bricks experimented on were London stocks, gaults, Leicester red, Staffordshire blue and Fletton. Single bricks, and in some cases half-bricks, of each kind were tested, and also the lime mortar and Portland cement mortar, and similar bricks built in piers or walls were tested, and at the end of the book you will find a table of averages giving the rates between the crushing weight of the brick and the crushing weight of the pier or wall. The book contains all the facts connected with the experiments and illustrations of the piers and walls under pressure and after failure, so that anyone can work out for himself the different ratios that he may want in connection with his own work; and the book is a very valuable record of an interesting series of experiments. I may mention that the building of the piers for series I. and II. was executed under the supervision at intervals of two members of the science committee, and a record of progress was kept, so that the age of each pier at the time of testing could be ascertained. The piers were built by a large firm of contractors at daywork prices, and it is with regret that the committee have to state that during the absence of the members the bricklayers, finding the Leicester red and Staffordshire blue bricks very hard to cut, filled in a great portion of some piers with closers of London stocks. This for experimental purposes destroyed the value of these piers, and the committee were obliged to have fresh piers built, but it incidentally affords a sample of jerry work which goes on under conditions when it would appear impossible. A comparison between these faulty piers and those built under the clerk of works affords some useful information, as it may be taken that similar scamping work occurs every day.

The subject of the standard size of bricks was taken up by the science committee in 1897, and a conference with representatives of the Institute of Civil Engineers and the Brickmakers' Association was held.

Now that the Royal Institute of British Architects has fixed the standard size of bricks it may be of interest to say a word or two on the subject. The standard size is:—1. The length of the brick should be double the width, plus the thickness of one vertical joint. 2. Brickwork should measure four courses of bricks and four joints to a foot. Joints should be ½ inch thick, and an extra $\frac{1}{8}$ inch, making $\frac{5}{8}$ inch for the bed joints to cover irregularities in the bricks. This gives a standard length of 9¼ inches centre to centre of joints.

The bricks, laid dry, to be measured in the following manner:—

A. Eight stretchers laid square end and splay end in contact in a straight line to measure 72 inches.

B. Eight headers laid side by side, frog upwards, in a straight line, to measure 35 inches.

C. Eight bricks, the first brick frog downwards and then alternately frog to frog and back to back, to measure 21½ inches.

A margin of 1 inch less will be allowed as to *A*, and ½ inch less as to *B* and *C*.

This is to apply to all classes of walling bricks, both machine and hand-made.

The size has been arrived at after a careful consideration of long lists of different sizes of bricks from all over the United Kingdom and Ireland, and, as will be seen, it is about the average size of London stocks. It is hoped that the brick users in the North will come into line, although no doubt it will take some time for the builders who have been accustomed to the larger bricks to take up this smaller size.

On the other hand, many architects object to the standard of four bricks and four courses measuring 1 foot, and say that, although they agree with the proportion of length to width, because that is the only way that good sectional bond can be made, the height of the four courses does not affect the question of bonding, and they would like this left open, so that those who want five courses of bricks and five joints to the foot can have them. I think that it is obvious that the standard must fix all the dimensions of a brick, and that it would be very undesirable to leave the height out of the standard, but there is no reason that I can see why architects who want the thin bricks should not have them in spite of the standard if there was sufficient demand for fancy sizes. Brickmakers would, I presume, always be willing to make them to order, and in fixing the standard we have pointed out that it applies to walling bricks only, as we thought it would be unwise to try and standardise facing bricks, at all events for the present.

The margin in the measurements is intended to allow for the difference between the walling and ordinary facing bricks. Most builders want the full bricks that measure 9 inches by 4⅜ inches by 2$\frac{1}{8}$ inches, with the $\frac{5}{8}$ inch bed joint, and the minimum brick that measures 8⅞ inches by 4$\frac{5}{8}$ inches by 2⅜ inches with the ½ inch bed joint would suit nearly all the usual stock-sized facing bricks.

The value of the standard to those brickmakers who have been making their bricks of the London stock size, and who have felt the unfair competition of those makers who have reduced the brick to lessen the cost of the carriage, will be that the bricks against which they have found it so hard to compete will now be brought up to a definite test, and will not be used where the standard is inserted in the specification.

There is another question that will have to be settled sooner or later, and that is the size of the frog. In some of the glazed bricks the frog has been so exaggerated that a section of the brick looks like the letter H; it is obvious that the strength of the brick is seriously reduced, and when used where there is much weight or exposed to the effects of fire the face flies off. In order to meet this it was suggested to try a brick with three 1-inch diameter holes; this would give 1$\frac{1}{8}$ inch bearing on each side, and 1½ inch between the holes; these holes would be also excellent for grouting up perpends and help the bricklayer in cutting closers.

Whether this would be open to the same objection as the perforated bricks with the smaller sized but greater number of holes I am unable to say, but these bricks are apt to fly when exposed to the effect of fire and water. The size of the frog is a serious item also, now that so much brickwork is carried out with cement. The best form of frogs are the two square shallow sinkings, but for brickwork in cement bricks are often specially made without frogs.

It would be interesting to know what amount of success attends the various fancy forms of bricks that are brought out, a fresh one almost every year; the only place that I have ever seen them has been at the Building Trades Exhibition. It seems hard that so much ingenuity and time should be wasted—or perhaps not wasted, but at all events lost.

Some few years ago Mr. Alan Munby drew up a very useful list of questions on building stones, and architects were invited to return the form filled up, with a view to procuring reliable reference on the subject of building stones, and the result was the presentation by Mr. Scorer of an interesting collection of building stones and information on the subject to the Architectural Association. The matter has not been carried on, but it is a pity that it should not have been worked out, as there is undoubtedly a great need for such information.

Structure can only be studied by microscopic sections, of which there are a good many at the Geological Museum, and a scheme to form a students' collection of building stones, giving all the information set out on this form, is in course of formation.

Strength Under Cross Strain.—Stone is a weight carrier with little transverse and less tensile strength. Use it, therefore, freely in compression, with caution in lintels and never in tension. Bring pressure upon it at right angles to its natural bed, or in the case of slate to its line of cleavage.

Uses.—A careful study of stone is necessary to know what are the purposes each is best suited for. In London Portland stone is considered the best, and other limestones, such as Bath, &c., are frequently used. The sandstones of Yorkshire and Forest of Dean are mostly used for landings and steps.

Chemical Analysis.—The value of this is the indication it gives of the lasting properties of the sample in sand-

Digitized by Google

stones; the nature of the cementing material which holds together the particles of silica is of all importance.

The sulphuric acid found in the atmosphere of large towns, the carbonic acid in the country atmosphere, will ultimately decompose any stone containing a large part of either carbonate of lime or carbonate of magnesia.

The oxygen of ordinary air will act on stone containing much iron. The average humidity of the neighbourhood in which the stone is to be used is another point, as the destructive acids penetrate more deeply into a wet than a dry stone and the frost has a greater effect. The position of the stone also has a bearing on the question; stones that are always in the shade and never dried by the sun decay most rapidly.

Any stone exposed to very different degrees of heat on its different surfaces is liable to crush from unequal expansion and contraction, and for this reason stone buildings are not so fire-resisting as brick buildings, and in the tariff regulations for insurance are charged for accordingly.

The readiness with which stone can be converted into the various shapes in which it is required for different kinds of work will depend in some cases upon its hardness, but will also be influenced by the soundness of its nature, by its freedom from flaws and also by its natural cleavage. A soft stone of even grain and without distinct beds would naturally be selected for carved work, while a hard stone in thin layers easily separated would be well adapted for building good and economical rubble masonry.

The pediments to the new Government offices recently built in Parliament Street were intended to be carved, in order to keep the joints in such position as they may interfere least with the carving blocks of stone, weighing 7 tons, which had to be hoisted 120 feet into the air and moved about on the scaffolding. When these are fixed in their places it is reckoned that the sculptor will cut away 50 tons of stone to produce the carving.

Hardness.—The hardness of stone is often of importance, but it does not follow because a stone is hard that it will weather well. Many hard stones are more liable to atmospheric influence than those of softer texture, whose chemical composition is of more durable nature.

The structure of wood affords the only reliable means of distinguishing the different kinds. Colour, weight, smell and other appearances which are often direct or indirect results of structure may be helpful in this distinction, but cannot be relied upon entirely.

Structure underlies nearly all the technical properties of timber, and furnishes an explanation why one piece differs as to these properties from another.

Structure explains why oak is heavier, stronger and tougher than pine, why it is harder to saw and plane, and why it is much more difficult to season without injury. From its less porous structure alone it is evident that a piece of a young and healthy oak is stronger than the porous wood of an old or stunted tree, or that Georgian or long-leaf pine excels white pine in weight and strength. Keeping especially in mind the arrangement and direction of the fibres of wood, it is clear at once why knots and cross grains interfere with the strength of timber.

Timber is furnished by two well-defined classes of trees—the needle-leaved, naked, seeded conifers (pines, cedars, &c.) and the broad-leaved trees (oak, poplar, &c.). The first are commonly called evergreens; the latter are known as deciduous trees. In the timber trade the woods of broad-leaved trees are known as hard woods, and the needle-leaved trees as soft woods.

In the manner of growth both conifer and broad-leaved trees behave alike, adding each year a new layer of wood, which covers the old wood in all parts of the stem and limbs. Thus the trunk continues to grow in thickness throughout the life of the tree by additions (annual rings), which in temperate climates are, barring accidents, accurate records of the tree.

Examining a smooth cross section or end face of a well-grown log of Georgian pine, you can see an envelope of reddish scaly bark, a small whitish pith at the centre, and between this the wood in a great number of concentric rings. A zone of wood next to the bark one to three or more inches wide and containing 30 to 50 or more annual rings is of lighter colour; this is the sap wood, the inner or darker part of the log being the heart wood. In the former many cells are active, and store up starch and otherwise assist in the life processes of the tree, although only the last or outer layer of cells (the cambium layer) forms the growing part and the true life of the tree. In the heart wood all cells are lifeless cases, and serve only the mechanical function of keeping the tree from breaking under its own great weight or from being broken by the wind. The darker colour of the heart wood is due to infiltration of chemical substances into the cell walls, but the cavities of the cells in pine are not filled up as is sometimes believed. Sap wood varies in width and in the number of rings which it contains; even in different parts of the same tree the same year's growth which is sap wood in one part of a disc may be heart wood in another. In a pine 250 years old a layer of wood or annual ring does not change from sap wood to heart wood until seventy or eighty years after it is formed, while in a tree 100 years old or less it remains sap wood only from thirty to sixty years, occupying the peripheral part of the trunk. The proportion which sap wood forms of the entire mass of the stem is always great. Thus even in old trees of long-leaf pine the sap wood forms about 40 per cent. of the merchantable log, while in young trees the bulk of the wood is sap wood. Holding a well-smoothed disc $\frac{1}{8}$ inch thick towards the light it is readily seen that pine wood is a very porous structure. If viewed with a strong magnifier the little tubes, especially in the spring wood of the rings, are easily seen, and their arrangement in regular, straight radial rows is apparent. Scattered through the summer wood portions of the rings numerous irregular greyish dots (the resin ducts) disturb the uniformity and regularity of the structure. The total length of the fibres is $\frac{1}{10}$ inch to $\frac{1}{4}$ inch, being smallest near the pith and is 50 to 100 as great as their width. They are tapered and closed in at their ends and thin walled with a large cavity or internal space in the spring wood, while they are thick walled and flattened radially with the internal space much reduced in the summer wood. The flattening together with the thicker walls of the cells produces greater firmness and darker colour; that is to say, there is more material in the same volume.

The dark lines on the side of the smaller piece appear when magnified as tiers of eight or ten rows of cell lying in vertical radial planes and are seen as bands in the radial face. These bands are the "medullary rays," and are common to all timber woods. In the pines they are quite small, but they can be readily seen even without a magnifier if a radial surface of split wood (not smooth) is examined. The entire radial face will be seen almost covered with these tiny structures, which appear as fine but conspicuous cross lines. The cells of the medullary rays are smaller and very much shorter than the wood fibres, and their long axis is at right angles to that of the fibres.

The large vertical resin-ducts are best observed on the removal of the bark from a fresh piece of white pine cut in winter, when they appear as white lines. Neither the horizontal nor the vertical resin-ducts are vessels or cells, but are openings between cells; that is, intercellular spaces in which the resin accumulates, freely oozing out when the ducts of a fresh piece of sap wood are cut. They are present only in coniferous woods.

The Anatomical Structure of Broad-leaved Trees.—On a cross section of oak the same arrangement of pith and bark, sap wood and heart wood may be seen, and the same disposition of the wood in well-defined concentric rings, but the rings are marked by lines or rows of conspicuous form or openings which occupy the greater part of the spring wood, and are, in fact, the openings through the vessels cut by the section. On the radial section the several layers appear as so many parallel stripes in the tangential face; patterns similar to those mentioned for pines are seen. But while the patterns in hard pines are marked by the darker summer wood and are composed of plain alternating stripes of darker and lighter wood, the figures on oak are due chiefly to the vessels, those of the spring wood being the most conspicuous, so that the darker shaded parts are the spring wood, the lighter parts the summer wood. Scattered through the radiating grey patches of porous wood are vessels similar to those of the spring wood, but decidedly smaller. These vessels are usually fewer and larger near the spring wood, and smaller and more numerous in the outer portion of the ring. Their number and size can be used to distinguish the oaks classed as white oaks from those classed as black and red oaks. The summer wood, except for these radial greyish patches, is dark coloured and finer. This finer portion, divided into bodies or strands by thin patches of porous wood and also by fine wavy concentric lines of short, thin-walled cells, consists of thick-walled fibres and is the chief element of strength in oak wood. In good white oak it forms one-half and more of the wood; it cuts like horn, and the cut surface is shiny and of a deep chocolate-brown colour. The large medullary rays in oak are often twenty and more cells thick and several hundred cells in height.

Mr. W. H. WHITE, who proposed a vote of thanks to the

Digitized by Google

author for his paper, said the question of materials was perhaps not so fascinating to the younger members of the profession as that of design, but it was of great importance to them and to their clients. It was upon their practical knowledge of materials that they would be able in practice to steer clear of the pitfalls which increased year by year for the architect. Every opportunity should therefore be taken by them to collect data, and in making such tests as they could upon materials in actual practice, because cases of litigation were becoming more and more frequent upon the question, and even experienced architects found it necessary to pay special attention to it. The speaker thought that the students in their visits to buildings in course of erection should carefully note and examine all materials that came under their notice, and if possible make experiments for themselves. He quoted a case in which some plastering on a job was found to be defective, and the surveyor, after examining the work, said the fault was due to bad sand. The speaker was able to prove, however, by a simple experiment on the spot, that the materials used were good and sound, and the defect was merely accidental. That was a practical illustration of the value of experiments which all of them could carry out. The difficulty was in knowing when they must and ought to condemn materials. It was easy to pass the best, but occasions arose which tested their knowledge in the other direction. In the course of a lecture of the kind they had heard that evening, it was quite impossible to touch upon more than a certain number of materials. Mr. Searles-Wood had, however, given them a lot of information which would serve as well as text-books. In conclusion, he said he wished to emphasise the point that the subject of the examination of materials was often left too late, until they had got into practice. Even before that stage they should have such knowledge as would enable them to give a decision quickly and with such precision that it would carry weight and show they understood their business. That could only be done by handling the materials and making experiments, and ascertaining what was best by notes and careful observations.

Mr. MATT GARBUTT seconded the motion, and said the author in his paper seemed to deal chiefly with concrete and its constituents and principally with concrete in relation to ferro-concrete structures. He noticed that when speaking of the aggregates to be used in concrete, Mr. Searles-Wood naturally referred to the point which to the ferro-concrete man was most important, namely, the strength of the aggregate, but he did not say that some of the materials mentioned, such as cinder, coke breeze, &c., were extremely dangerous. The paper referred also to the desirable test load as being not more than one and a half times the accidental load. He believed that that was sometimes put into specifications, but it appeared to him important that some general statement ought to be made as to the factor of safety which modified some of the rules of the accidental load. If they allowed a structure to be loaded beyond its elastic limit for any great length of time it would fail, a fact illustrated in many old buildings, especially in brickwork. As to the use of cement to the exclusion of lime in concrete, there again Mr. Searles-Wood had looked at the question from the point of view of the ferro-concrete man who wished to know what would happen to a structure during its first years of life with as much precision as possible. Of course they could not prophesy quite so well what would happen to a structure in which lime formed a constitutional part. On the other hand, in structures where concrete was wanted in mass, and they were not ferro-concrete structures, lime had advantages. He agreed with the author of the paper that for ferro-concrete work Portland cement only should be employed to the exclusion of cheaper and less reliable materials, but he did not know whether chemists were at present absolutely satisfied with the permanent stability of Portland cement as compared with materials in which hydraulic lime of some sort was used. In speaking of the preservation of iron in concrete, old illustrations were sometimes safe, though it was not always mentioned that in such instances the lime used was hydraulic lime of some kind, but still it was not Portland cement. The chain round the cone of St. Paul's was a popular example. The point which was made about particles of lime in certain bricks was important to the young architect, and he could not attach too much responsibility to the refusal of such bricks. If they noticed white specks on bricks the safe policy was to reject them; they might be harmless, but if the spots were lime, caused from ground fossils, the particles would in time cause the bricks to swell, and so loosen the structure and cause grave trouble.

Mr. HAMPDEN W. PRATT said he was more specially interested in the part of the paper which dealt with brickwork. One seemed to have to do with bricks in every building, and the difficulties to be surmounted could hardly be realised until one came to deal with them in actual practice. As to the standardising of bricks they had heard a great deal about it, but so far as he could judge nothing had been carried out. Manufacturers had been approached and requested to put on the market the dimensions definitely specified, but they had met the proposal only to a very limited extent. The principal difficulty he found in dealing with bricks of different sizes was when work had to be faced on both sides. It was mostly in the thickness of the brick that the difficulty lay. Standardisation would be an advantage, but in hand-made bricks it was almost impossible to work to a size, and the only hopeful solution was in a machine-made brick. With regard to pressed bricks and those machine-made, he would have liked to have heard some comparison drawn between them as to the various qualities and advantages. Machine-made bricks seemed now to imitate the hand-made, and sometimes it was difficult to distinguish between the two. He wondered whether Mr. Searles-Wood had come across a brick he, the speaker, had used in a small quantity. It was a brick made in this country under a German patent, and the process of manufacture was by boiling instead of baking. It had exceedingly good texture, good shape, and was made in several colours. In the Reading district this brick had been largely used, and was said to be a good weather material.

Mr. H. A. SATCHELL agreed that the study of materials was more important to the architectural student than designs, for when starting practice they should be conversant with the pros and cons of all building materials, and knowledge of that kind was only acquired by careful preparation and study. It was difficult to understand why certain bricks had lost their reputations, and he concluded the cause was mainly due to the introduction of new makes. It was disconcerting to hear that in the experiments carried out under the very eyes of the Institute irregularities had been discovered in the bricklayers' work. When the science standing committee of the Institute found it difficult to get honest workmanship in their tests, it became hopeless for the architect in practice to expect better treatment. He wished Mr. White would take them into his confidence and explain the rough and ready test he applied to ascertain the character of the plaster which proved to be unjustly condemned.

Mr. W. H. WHITE in response to the last speaker, and at the President's request, said they would find that by taking a piece of old lime plaster, pounding it up, and putting it in a glass of water and shaking it the sand would settle on the bottom, and in due proportion to the specific gravity the lime would float on the top, and the hair, if there was any, above it.

The vote of thanks was carried by acclamation, and Mr. Searles-Wood briefly replied.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

AT a meeting of the above Society on the 14th inst., Mr. H. Phillips Fletcher, F.R.I.B.A., F.S.I., A.M.I.C.E., read a paper on "Georgian Domestic Architecture."

Mr. Fletcher explained that Georgian architecture was the name given to the architectural style principally in vogue in the eighteenth century, and noted that it was the English expression of the great Renaissance movement.

He traced the influence of Inigo Jones and the effect of his visits to Italy in the middle of the seventeenth century. He also pointed out how Wren nurtured the style with his borrowings from the architecture of the Netherlands, producing buildings so peculiar to this period. The lecturer attributed the decay of Georgian work to the age of the succession of revivals and pointed out its reintroduction some twenty years ago under the name of Queen Anne.

A house in the Close at Salisbury was taken as typical of the smaller house, and the well-proportioned sash windows and stout wooden bars were noted, the most predominant feature being perhaps the central doorway with its consoles and the boldly projecting consoled cornice.

The lecturer then analysed the characteristic features of the style and remarked that Wren popularised red brick walls, although in suitable districts stone was much employed. The Swan House in Chichester was quoted as a good example of rubbed brickwork with the employment of raised blocks at the angles.

Digitized by Google

A doorway at West Wycombe was taken as being a simple and satisfactory example in which fluted pilasters and a simple cornice were used. It was pointed out that doorways were finely executed in wood, and formed a strong contrast to the Italian marble doorways of the same period. The doorway at Mr. Seymour Lucas's house with its typical shell hood was also shown on the screen.

The windows of the sash type set flush with the wall were taken as being typical of the style, and it was noted that such windows were considerably smaller than those of the Jacobean period.

The introduction of external shutters from Italy was also borne in mind and their effect upon the scale and appearance of the buildings was also considered. It was pointed out that the cornices projected boldly and formed special features, and it was also shown that they were frequently of wood and often carried right round the house. The method of roofing was then dealt with, and that at Tyttenhanger, Herts, was taken as being characteristic. The effect of its reposeful skyline and the dignity and unity of design were contrasted with the numerous gables so frequent in many modern houses. The feature that Georgian architects made of chimney stacks and their symmetrical grouping was also dwelt upon.

The lecturer then dealt with the treatment of internal work. Commencing with the walls, he pointed out the frequent division of the same into three, viz. the low dado, the large panel and the cornice, which gave a certain breadth to the whole which was sometimes wanting in Jacobean work. The framing of the doorway in one of the Classical orders was also noticed. Examples of the rich treatment of the fireplaces were also placed upon the screen.

The lecturer also described the bold and effective Georgian staircases and the geometrical treatment of the ceilings.

Mr. Fletcher then dealt with the grouping of smaller houses together, which produced such fine designs, and took the terraced houses at Stamford as characteristic of the style. He then showed an example of another house in Salisbury Close, showing the plain simple treatment for a detached town house.

Eltham House, Kent, was treated as a good example of the simple block plan for a country house, and Groombridge Place, Kent, was shown with its H shaped plan.

Houses having a centre block with wings were then dealt with, and many slides of Stoke Park, Northants, Blenheim Palace and many other buildings were shown upon the screen. The town mansion was then dealt with, and Marlborough House, London, and Kensington Palace were shown.

In conclusion, Mr. Fletcher pointed out the appropriateness of the different buildings to their special requirements, and the homely comfort of the smaller buildings contrasting with the stateliness and grandeur of the large buildings. He also noted the tendency in certain directions towards simplicity in design at the present time, and hoped that the study of Georgian architecture would assist in this direction, and specially pointed out that the motif of much of the Georgian work was suitable for houses of the present day. He said that he thought the successful results of the period were due to a very large extent to the very extensive and diverse attainments of so many of the Georgian architects, which gave them the facility of grasping at once the measures that in each individual case would be appropriate. He considered that the versatility and refinement in Georgian design was due largely to the liberal education of the architects, who did not confine themselves to the study of their profession alone, but many were in addition either skilled mathematicians, astronomers, dramatists, and even, so it is rumoured, not indifferent performers with the rapier. The lecturer thanked his brother, Mr. Banister Fletcher, for having placed his collection of slides at his disposal, and he mentioned the fact that this marvellous collection contains over 7,000 slides, a very large number of which were made from photographs specially taken in various parts of the world by Mr. Banister Fletcher.

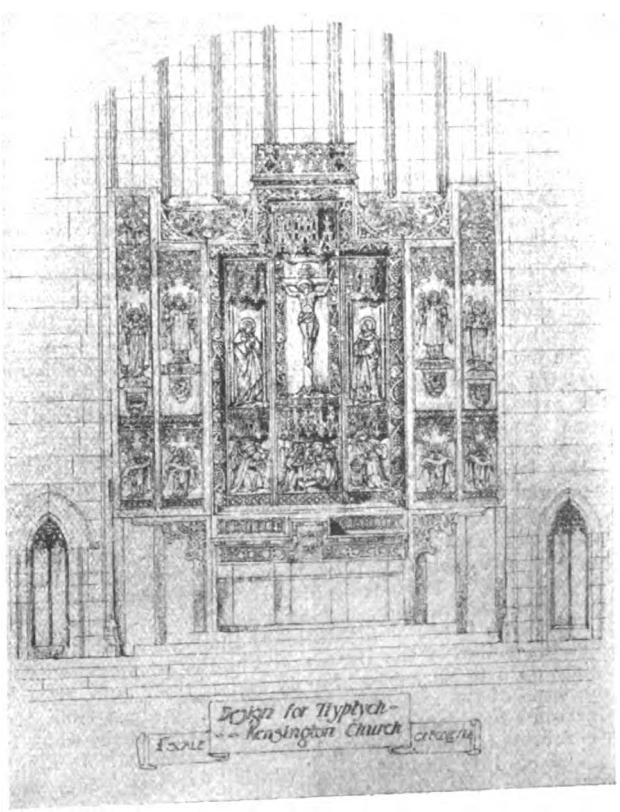
Mr. R. B. Preston, architect, South King Street, Manchester, and Disley, has been successful in a competition for a library at New Mills, Lancashire.

Mr. Banister Fletcher will deliver an illustrated lecture on Monday next at the University of London, South Kensington, on "The Belgian and Dutch Renaissance."

The Louth Antiquarian Society have arranged, subject to satisfactory terms, to lease a site for a museum in Enginegate for seventy-five years from the Town Council at 5*s.* a year.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]



Architects Beware!

UNDER this heading we inadvertently published two letters signed "F.R.I.B.A." and "Another F.R.I.B.A.", on November 27 and December 4 last. The first letter, by way of warning architects, cast aspersions upon a highly respectable stone-cleaning private company recently incorporated, though its name was not actually mentioned, stating or implying that the directors were unfairly exploiting the names of well-known architects in order to obtain capital for the company. The second letter echoed the sentiments of the first. The architects alluded to had been invited to witness a small demonstration of stone cleaning, but no use has been made by the directors of the fact that some of them attended, and the company has never appealed to the public for financial support, being as before mentioned a private company with the necessary capital already subscribed. We find that the statements of fact in the letters are quite untrue, and we regret that we allowed them to be published.

Memorial to the late George Frederick Bodley, R.A., D.C.L.

SIR,—A desire has been widely expressed among the personal friends of the late Mr. G. F. Bodley that a suitable memorial should be erected to record his eminent services to the cause of art and architecture.

A representative committee has been formed to carry out

this object and invite subscriptions for the purpose. At a meeting of the committee held in the parish room of the Church of the Holy Trinity, Kensington Gore, on Wednesday, December 9, 1908, it was unanimously resolved:—(1) That a suitable memorial should be erected in the Church of the Holy Trinity, Prince Consort Road, Kensington Gore, one of the most recent and most beautiful churches built by Mr. Bodley; (2) that it should take the form, if funds permit, of erecting the noble reredos which he himself had designed and so much desired to see carried out; (3) that a commemorative tablet, with a portrait of Mr. Bodley and suitable inscription, should also be erected in some other part of the church.

Digitized by Google

The committee feel assured that there are many friends and admirers of the late Mr. Bodley who would like to associate themselves with this memorial, but whose addresses being unknown, can only be reached through the public Press.

An account has been opened at the London and County Bank, Knightsbridge, S.W., into which cheques may be paid, made payable to the "Bodley Memorial Fund," or they may be sent to the hon. treasurer, the Rev. H. B. Coward, M.A., Church of the Holy Trinity, Prince Consort Road, Kensington Gore, S.W., by whom they will be acknowledged.

Signed on behalf of the committee, HALIFAX.

Plumbing and Plumbers.

SIR,—I am directed by my committee to state in reference to the letter from Mr. W. Challoner appearing in your issue of January 8, that this Association repudiates Mr. Challoner's apparent assumption that he is the only person entitled to speak authoritatively on behalf of plumbers generally in this country.—Your obedient servant,

A. A. ADAMS, Secretary.

The Associated Master Plumbers, 16-17 Devonshire Square, Bishopsgate, London, E.C.: January 15, 1909.

Winchester Cathedral.

SIR,—I am pleased to see in your current issue the letter from Mr. T. G. Jackson, as it relieves my mind of some doubts that have troubled me, as an architect and an Englishman, with reference to Winchester Cathedral. I am glad to learn that when paragraphs go the round of the Press announcing that further donations are required from the public in consequence of the "discovery" of further defects, we are to understand the word "discovery" in the limited technical sense in which it is employed by lawyers, and for which in ordinary parlance we should say "disclosure."

In the appeal printed and circulated on behalf of the Winchester Cathedral Fabric Fund, and containing a list of donations to April 26, 1906, amounting to close on 16,000*l.*, reports by Mr. Jackson and the late Mr. Colson are given, but "extracts" only from Mr. Jackson's report of July 3, 1905. Appeal is made for a further sum of 12,000*l.*, and the public might justifiably understand that the works mentioned by Mr. Jackson and Mr. Colson, when carried out at the cost of 28,000*l.* or within a reasonable margin of that amount, would make the fabric of Winchester Cathedral safe. But in the year 1907 further defects were disclosed to the public, and appeal was made for contributions to the amount of 86,000*l.* In 1908 a yet further appeal for 7,000*l.* was made, and as a justification were disclosed the works to the north transept and the buttresses of the north aisle, not a word about which is mentioned in the appeal to which I have first referred.

In my own practice as an architect I have always found that the Philistine, whom Sir Hubert Herkomer defines as the average man of average intellect, when disturbed by some untoward manifestation in his building, requires a complete examination and report upon the whole building, and I advance on behalf of the Philistine, to whom the Dean and Chapter must look for the funds they require, that he is justified in supposing that such an examination and report on the whole fabric of Winchester Cathedral has been made by Mr. Jackson. Why, then, these belated discoveries, disclosed, as we learn from Mr. Jackson's letter, long after they have been made?

Criticism is one of the duties of the Press, and I submit that the policy of the Dean and Chapter of Winchester is fairly open to criticism. Surely it was their duty prior to the issue of the appeal in 1906 to have obtained from Mr. Jackson a complete report as to the condition of the whole of the fabric of Winchester Cathedral. Possibly Mr. Jackson's report of July 3, 1905, from which "extracts" only were given, was such a complete report.

Surely it would have been wise to disclose then the whole situation, and to have appealed for 100,000*l.* or a quarter of a million, or whatever amount Mr. Jackson might have advised as necessary to put into a safe condition the whole fabric.

The Philistine, who in response to an appeal for 28,000*l.* has given 100*l.*, might then, if his means permitted, have subscribed 500*l.* Now he has probably bestowed his charity on some other deserving object.

I regret that my somewhat loose use of the words "the east end of the church" has apparently misled Mr. Jackson as to the buttresses to which I referred. If I had said "eastern part of the church," he might perhaps have inferred that I meant the buttresses to the south aisle of de Lucy's building, which are mentioned in the report of the late Mr. Colson as having a similar influence to that of the buttresses to the north aisle.

I still think that my suggestion as to the penetration of cement grout to the peat is not unfounded. The fissures in the walls extended to the foundations, as may be seen from the photographs in the appeal of 1906, and below the foundations was merely a very thin stratum of soft chalky marl above the peat, easily penetrated by a bar, as is described in Mr. Jackson's own report. Mr. Francis Fox, in his lecture at the Institute, told us that twenty-five tons of cement were injected into one hole. Who can say where this enormous quantity went? The effectiveness of the repairs to Winchester Cathedral must to a large extent depend upon the absolute infallibility of the grouting machine, and I submit that it is perfectly legitimate criticism, and in no sense "captious," to call attention to facts, the knowledge of which is public property, that apparently discredit that infallibility.

THE AUTHOR OF THE ARTICLE "ARCHITECTURE IN 1908."

GENERAL.

Mr. Edwin T. Hall, V.-P.R.I.B.A., will open to-day, the 22nd inst., a discussion in the Municipal School of Technology, Manchester, on "The Manchester Royal Infirmary from the Hygienic, Sanitary and Æsthetic Points of View" in connection with the Royal Sanitary Institute. Mr. E. T. Hall will be followed by Mr. John Brooke, F.R.I.B.A.

John W. Beatty, director of Fine Arts, Carnegie Institute, Pittsburg, announces the dates for the thirteenth annual international exhibition of paintings in oil at the Carnegie Institute. Entry blanks must be received from Europe on or before February 25 next.

Mr. W. Kaye Parry, M.A. Dublin University, M.Inst.C.E., F.R.S.I., has been appointed external examiner in sanitary engineering in the Faculty of Technology in the Victoria University of Manchester.

Mr. James Neale, F.S.A. and F.R.I.B.A., who was Pugin Student in 1875, died on the 18th inst. very suddenly at 10 Bloomsbury Square, W.C.

A Meeting of the Architectural Association of Ireland was held last week in the Leinster Lecture Hall, Molesworth Street, Dublin. The president, Mr. Edwin Bradbury, M.R.I.A.I., occupied the chair. The principal speaker was Sir Aston Webb, R.A., F.R.I.B.A., whose subject was "A Talk to Students."

Mr. Francis Griffiths has added to his series, "The Library of First Principles," a new illustrated volume entitled "English Church Architecture," by Mr. G. A. T. Middleton, A.R.I.B.A.

The Special General Meeting of the R.I.B.A., announced for the 25th inst. to hear a paper by Mr. W. Dunn on the "Amendment of the London Building Acts," has been indefinitely postponed.

The Council of the Surveyors' Institution have decided that after the election of members to be held in October 1913 no examination candidate shall be eligible for election as a Professional Associate unless he has passed both the intermediate and final examination of the Institution. As a consequence of this change, after the present year candidates for the intermediate examination will be allowed to sit at the age of nineteen and for the final examination on completing their twenty-first year.

The Sum of 20,347*l.* is still required for the completion of the works at Winchester Cathedral. The estimated total expenditure is 86,806*l.*, and of this 66,458*l.* 11*s.* 5*d.* has been received or promised.

Messrs. Briggs & Wolstenholme, architects, of Liverpool and Blackburn, have been commissioned, it is reported, to draw plans for the erection of big works at Flint, on the Cheshire border of Wales, for the manufacture by a German firm of a patent lustre silk. The cost of building will be about 50,000*l.*

The Board of Directors of the American Institute of Architects recommends that the gold medal of the Institute be awarded biennially, alternately to a foreigner and to an American: that the recipient be nominated by the board; that, subject to the ratification of the convention and his attendance in person, it be conferred at the following convention. This year the board of directors recommends that the gold medal of the A.I.A., the first to be conferred upon an American, be awarded to one whom it thinks preeminently worthy to be honoured, one who has set a standard for high achievement in architecture, who has generously and wisely advanced the cause of architectural education, and who, as shown in the Washington plan, has grasped and expressed the need of civic beauty, Charles Follen McKim.

The Architect.

THE WEEK.

THE dangers of petrol are still being enforced on the attention of the public, and Colonel N. WILLOUGHBY WALLACE, in lecturing to the members of the Royal Automobile Club, emphasised the peculiar danger of the partially-filled or empty receptacle, and pointed out that in Germany, Austria, and Hungary the law already provides, and in Italy, Norway, and Russia is about to make provision, that petrol and other inflammable liquids may be transported and stored only in receptacles fitted with a safety device that will prevent explosion from fire and heat. Such devices are therefore possible, and are in use on the Continent; and the adoption of them would go far to reduce the danger that is so imminent in Britain. We do not suppose that any such device can be made, as the Americans say, fool-proof; and carelessness always seems to be the accompaniment of familiarity with danger.

THE art of the late GEORGE FREDERICK WATTS, though it may not meet with universal admiration, appeals so generally to architects that we are glad to know that coloured photogravures, which faithfully translate his oil-paintings, are now being published, and those of his pictures, *Endymion*, *Love Triumphant*, *Hope*, and *The Man who had Great Possessions* have already been issued.

WHEN the results of the dangerous and laborious travels of Dr. M. A. STEIN in Eastern Turkestan and the desert lands between that country and China have been fully made public, we shall probably have before us some highly interesting data as to the life of Central Asia in the earlier centuries of the Christian era and the centuries immediately preceding. Particularly there appears to have been collected an immense amount of early Buddhist literature which may prove especially informing. The translation of these must, however, necessarily occupy considerable time, as the number of competent masters of Central Asiatic languages prior to the tenth century of our era is not large.

ONE can well understand the dismay of the Children of Israel when they first viewed the walls of Jericho in the light of the discoveries made by German explorers during the past year. Walls 20 feet high, built of masonry whose method of construction reminds us of Pelasgic work, are surmounted with 8 feet of clay-brick, which was probably at one time considerably higher. On the northern side there is a considerable breach, which may have been that by which the Israelites entered. By what means this breach was formed and how far it accords with the traditional account in Scripture, still remains to be proved.

HOLY TRINITY CHURCH, KINGSWAY, has been condemned as a dangerous structure and will have to be rebuilt. The cause of the subsidences that have brought about the catastrophe is stated to have been the construction of Kingsway and the tunnelling of the Great Northern, Piccadilly and Brompton Tube Railway. To avoid litigation the sum of 1,500*l.* has been accepted by the vicar and churchwardens as compensation, but the expense of rebuilding will far exceed this amount.

THE New Year number of *The Architectural Record* (New York) contains an interesting series of illustrations of recent bank buildings of the United States, and furnishes a capital epitome of modern American architecture, affording convincing proof of its eclecticism in the matter of style, ranging from the New Art of the National Farmers' Bank at Owatonna, Minn., the work of Mr. LOUIS H. SULLIVAN, to the pure Greek Doric of Mr. CASS GILBERT, the present president of the American Institute of Architects. Mr. GILBERT is not the only American architect who considers that pure Greek detail is a suitable clothing for the architectural expression of a modern bank, and there is something to be said for the idea when we remember that the earliest buildings used as banks of which we have any remains were Greek temples, which seem to have safeguarded the moneys of individuals as well as of the State and the hierarchy. The universal rule of low interest with high security obtained, for as the sacred character of the temples gave, to all intents, absolute security, the interest was nil. It is possible but scarcely probable that such structures as the Tholos or Treasury of ATREUS at Mycenæ may have served as banks rather than as store-houses of single individuals. Next to Greek, Roman Classic work has formed the basis of many American designs for banks and with equal archæological warranty, for banking amongst the Romans was highly systematised. We do not wish, however, to be understood to imply that pure Greek and Roman Classic detail monopolise the field of modern American architecture in bank building; there are plenty of other modes, even to the New Art example we have already mentioned, a building that must in fairness be admitted a very capable work.

WE can scarcely be expected to agree entirely with Sir HUBERT VON HERKOMER in his strictures on journalistic criticisms of art. No doubt if the man in the street, the Philistine, as Professor HERKOMER calls him, possesses the critical faculty, that faculty may be warped by too great reliance on the opinion of others, but very few have the time and opportunity to so train their critical faculty as to enable them to form a correct judgment in matters of Art, where personal predilection or taste plays so large a part in the estimate formed by most people. The man who knows what he likes but does not know why is the most likely to be caught by the clap-trap productions of the soi-disant artist who plays to the gallery, and Professor HERKOMER would hardly maintain that this is ideal. Undoubtedly, if professional criticism were abolished and individual preference substituted, the maker of the pretty picture, the selector of the alluring title and the apt quotation would score heavily, to the detriment of the skilful craftsman and the high-minded thinker. The real critic must subject himself to a severe course of self-discipline, he must never allow himself to form an opinion without excellent reason, he must make sure that his judgment is trained by a well-directed course of study, and the laborious attainment of adequate knowledge. Then his criticism is valuable and informing.

PROFESSOR HERKOMER seems to feel most the injury that may be done to painters by the "slating" of journalistic critics, but real criticism is not all "slating." It is the duty, and we think we may also say the pleasure, of the genuine critic to point out what in his trained judgment appear to be merits, and not only to stigmatise defects or weakness. The expert critic knows that it is impossible to please everybody, and hence that it is easy to find fault. We are forcibly reminded of these facts by the criticism of Mr. SYDNEY PERKS, at the last meeting of the Royal Institute, on the very excellent paper read by Mr. R. STEPHEN AYLING on Public Abattoirs. Mr. PERKS found fault with Mr. AYLING because the latter did not exhibit amongst the plans illustrating his lecture any of his own designs, wherein we think he showed good taste, as it has been rather justly remarked that many readers of papers at the Institute on specialised subjects have taken advantage of the occasion to advertise their own works or to show what they could do if they had the chance. All the more praise therefore is, we think, due to Mr. AYLING for having collected a great deal of valuable information and modestly effacing his own personality. Fault, however, is found with him for avoiding that for which others have been blamed. This is not criticism.

THE ETHICS OF COMPETITIONS.—I.

ARE architectural competitions moral or immoral? Are they right or wrong? In the first place, in the abstract, and, secondly, in the manner in which they are conducted.

In the abstract. Is it right that a number of architects should be called upon to prepare designs for the same building, one only of which can be carried into execution, and for which one designer only can receive the due reward of his time, labour, and ability? Do the unsuccessful ones reap any advantage, or are their efforts entirely wasted?

To answer these questions we must first inquire to what category of affairs architectural competitions rightly belong. Whether they are purely gambling or whether they are of the nature of legitimate speculation. We may take it as generally accepted that unmitigated gambling is wrong, but that legitimate speculation is right. The man who risks his money on an event of which the circumstances are beyond his control or his prescience is a gambler. To back a certain horse, of which one knows little or nothing and over which one has no control, to win a certain race, of which the precise conditions cannot possibly be foretold, is gambling; and so also is the hazard of property on the throw of a dice, the motion of a roulette ball, the turn of a card. But all betting is not gambling; the owner and the trainer of a horse know sufficient of his capabilities, not necessarily to absolutely and infallibly predict the result of his performance, but to arrive at a reasonably accurate forecast. For them betting is not gambling, but legitimate speculation. They are on the same plane with the farmer who sows his seed, ignorant of how the extent of his crop may be influenced by the weather; with the merchant who buys and sells, imports and exports, without being able to predict with absolute certainty the turn of the market or the accidents of transit. Despite the element of chance, their procedure, like that in many other walks of life, is rightly regarded as legitimate speculation, and without legitimate speculation the world—or, at least, the civilised world—could not exist.

In every architectural competition there must admittedly be an element of chance. An architect may do all he knows to produce the best design of which he is capable; he may spare no pains to acquire the best information, give his highest thought to evolve his design, and may illustrate his scheme by the best draughtsmanship that he or his assistants can execute. There is still the possibility that some other competitor may send in a better design. But, presuming that he knows that the competition will be fairly decided, the element of chance does not remove the competition from the field of legitimate speculation. If, on the other hand, there is a doubt as to whether fair treatment will or will not be accorded to all competitors, then we may rightly class this particular competition as a gamble. There is also the possibility—less probable in the present than in the past—that our imaginary competitor may know that the competition will be unfairly decided, but in his favour. Then he is on a level with the trickster who plays against gamblers with loaded dice or marked cards. He is a blackguard, and the competition a swindle.

There is yet another aspect in which we may view an architectural competition. Amongst all men, and particularly—we perhaps flatter ourselves in our insularity—among Britons, there is a passion for emulation, for endeavouring to do something better than other men, which finds its expression in all forms of athletic exercises and games of skill. In these the chief incentive is not the hope of reward, but the pleasure of victory. The laurel wreath or the bronze tripod of the Greeks, the bronze, silver, or even gold medal of our own times, is intrinsically no adequate recompense for the expenditure of effort by which it is obtained. It is only a prize by virtue of its symbolism and evidence of superiority. This is sport, and in architectural competitions the element of sport undoubtedly largely enters, particularly amongst younger men, in whom the love of sport is the most active. There is another concomitant of sport. The effort to win leads a man to train for a race, to practise assiduously for a billiard match, and thereby he improves his physical powers or his skill.

Architectural competitions then belong to the categories of legitimate speculation and sport, and as such are, in the abstract, right and not wrong, moral and not immoral. As legitimate speculation they are right for the business man, as sport they are beneficial not only to the one who wins but also to those whose attempts have not been successful, since they have by their attempts improved their powers of design, their ability as architects, their development as artists.

We have still another question of high importance. Are competitions, in the abstract, beneficial to the art of architecture? The ideal of architectural competitions is the production of the best design for any particular building and the discovery and encouragement of unrecognised talent and ability. As regards the latter point there can be no question that the ideal is realised. In the two most important competitions of recent times, those for the Liverpool Cathedral and the London County Hall, the best designs, in the opinion of the assessors, were those of young and unknown men, Mr. GILBERT SCOTT and Mr RALPH KNOTT. These are not isolated instances but are sufficient to prove that open architectural competitions do result in the discovery and encouragement of unrecognised talent and ability.

Now we must consider whether competitions lead to the production of the best design. The alternative to a competition is the selection of an individual architect to whom is entrusted the task of preparing the best design. Will he accomplish the task? It must be assumed that he is selected on the ground of his recognised ability as proved by his executed work, and on this ground alone. This necessarily excludes the unknown genius. Can we be sure that the architect of proved ability will indubitably evolve the best design of which any man is capable? Is there any guarantee that because he has done excellent work in the past he will in any particular instance do equally good work, still more that he will do the best possible?

What do we find in all departments of mental activity? In literature the "one book man" is a well recognised individuality; in painting, in sculpture, in music we constantly find that an artist reaches the high-water mark of his powers in some great creation to which his subsequent productions never attain. It is almost a truism that when an artist is elected a Royal Academician the excellence of his work declines. There are many reasons for this; the relaxation of effort after success, age, health, worry, all depress a man's capability. With an architect especially the success that has brought him work brings also cares and worries in the carrying out of that work, and these diminish his artistic power. The level of an artist's achievement is never constant. It may, if he does not live too long, be constantly on an ascending plane; it may have reached the zenith and ever afterwards decline to a greater or lesser extent; it may fluctuate up and down the scale of excellence.

There is therefore no guarantee that because an architect has in the past designed a building, superlatively excellent in its artistic power, that he will do so in the future, or that in any particular instance he will give us the best possible design.

Again, an architect who has won his spurs has done so by the use of opportunity obtained either by competition or by direct commission. The possibility of lesser achievement in the future applies equally in either case, but in the latter there is a still further possibility. Many of the architects of our own time, whose artistic powers are rightly recognised, have made their reputation in the carrying out of direct commissions. Under favourable circumstances of site, funds, and other conditions, with clients who have given them free scope, they have produced admirable buildings. There is no assurance that other architects, under similar circumstances, would not have done better. Indeed it would seem that the pro-

Digitized by Google

bability is that they would, for it has almost invariably happened that when architects of great reputation, built solely upon work obtained by direct commission, have been induced to enter into competitions, they have failed to sustain their reputations in comparison with their fellows, and have proved their inferiority to those who have made a reputation in the arena of competitions as well as to hitherto unknown men. The competition for the London County Hall particularly emphasised this truth.

On the other hand, we have had repeated evidence that architects who have made their reputation by work obtained in competition have subsequently, as the result of direct commission and under favourable circumstances, produced some of the best work of our time.

We are forced therefore to the conclusion that, in the abstract, competitions lead to the production of the best design, to the recognition of latent ability, and to the benefit of the art of architecture.

(To be continued.)

STEELWORK.—III.*

By C. V. CHILDS, A.M.I.C.E.

THE steel-frame building in its up-to-date American practice is comparatively new to London. Several examples, however, have lately been erected, such as the Ritz Hotel and the *Morning Post* building.

It seems strange that the American practice, if adaptable to English buildings, should have taken so long in establishing itself in this country. Is it because English engineers are not conversant with, and are behind the times in regard to steel structural work?

This can hardly be the case. Perhaps the writer may be excused giving an example of his own experience in order to prove that this is not so. Just before leaving America in the year 1893 the last work he was engaged on was the design of the steel framework for the fourteen-storeyed "Carnegie Building," now the head offices of the Steel Trust in Pittsburg; and yet in the last fifteen years' practice of designing the steelwork for English buildings in no single instance could the American methods be adopted with any degree of economy.

The conditions in the building regulations † of the two countries are entirely different. The very origin of the steel frame was to evolve a scheme by which the thickness of the walls could be reduced to a minimum—that is to say, however many storeys might be built, the thickness of the walls need be no more than for a one or two storeyed building.

The building laws of the large American cities at once recognised the new order of things, and this fact alone made it possible, as well as profitable, to construct the so-called "skyscraper."

Here a very different state of affairs exists. Our Building Acts, framed to regulate building construction before steel became such an important factor as a structural material, still require that the thickness of the walls shall be proportioned according to the height they are to be carried up.

What such a thickness should be at the ground level of, say, the new "Singer Building" in New York, passes beyond the comprehension of even the framers of the Acts.

The laws are certainly obsolete, but they have been the means of effectually squashing any tendency on the part of our buildings to soar skywards. The general expectation is that the building laws will soon be modified more out of deference to the wishes of the erectors of ferro-concrete buildings than to those of the steel constructors; if this is done the constructional steelwork manufacturers should certainly see that their interests are safeguarded and that they are put on at least an equal footing with the ferro-concrete contractors. Walls carried on steel girders are certainly, for many reasons, more to be depended upon than those that rely on the composite strength of the concrete and a few small steel rods embedded in it. So that any alteration likely to be made in favour of the latter mode of construction should apply also to the former, which has stood the test of being in actual use for a much longer period.

The effect of the thickness of the walls being proportioned according to the height they are to be carried up is that the walls are not only capable of supporting their own weight, but also a considerable amount in excess, which, of course, was the primary object in framing such a regulation.

The steelwork designer has to be careful in calculating the pressure due to wall and floor loads that the brick piers sustain; if this pressure should be excessive, then the load or a portion of it must be transferred to a steel stanchion; but any stanchion which is inserted where the brickwork is capable of carrying the load is only so much waste material. The value of the unnecessary steel stanchion is not only thrown away, but a good deal of extra expense may be incurred in having to cut chases in the stonework to fit the flanges of the stanchion; the brickwork, too, has to be built in and around it, and the bonding is to a great extent spoilt thereby.

This extra cost of labour is also incurred where the walls are carried at each floor level and is frequently the cause of trouble and delay, especially where chases have to be cut in granite cornices and clamped and bolted back to the steel girders. All work of such description should be reduced to a minimum for the sake of economy; the cost of this does not appear in the price of the steelwork, but it may mean a considerable item in the masonry account.

One advantage claimed for the steel framed design is the rapidity with which the building can be erected; certainly some of the American buildings have been built in marvellously quick time. When in Pittsburg at the end of October, 1902, the writer had a photograph taken of the "Farmers' Bank," a twenty-four storeyed building, showing the steelwork of the roof completed, the floors all in, and the walls built up to within three storeys of the top; and yet no steel had been delivered at the site till after the first week in July.

The reason that such rapid construction is possible is entirely due to organisation in arranging and timing for the delivery of the materials at the site at the exact moment they are required. The building is half built before it is begun on the site. The secret of this depends on one drawing, and that is an accurately dimensioned plan of the site, from which all trades can obtain any desired measurements they may require, not by scaling, but by calculations; then the positions of all stanchions, walls, &c., can be exactly determined. It is the lack of this that causes so much trouble and delay in English buildings; each trade is generally expected to take their own measurements from the site, with the result that the steel contractor is frequently almost vainly endeavouring to obtain measurements over piles of rubbish and stacks of bricks, when the steelwork is urgently wanted at the site. How simple it all becomes when once the dimensions are obtained and settled; what is wanted is that the steel tape and theodolite should displace the use of the ten-foot rod and roll of string, and that, if possible, before the old building is cleared away to make way for the new.

Broadly speaking the difference between the steel-frame building or American practice and the semi-steel frame or English practice is that in the former each storey is dealt with separately; all the loads on the girders of any one storey, whether from external as well as internal walls, chimney-flues or floors, are supported on girders at the floor level of that storey. In the latter the practice is to carry the main walls at as low a level as practicable, e.g. over the shop fronts, at the first-floor level, or at that floor level above which the wall is capable of sustaining the pressure due to its own weight, as well as any other superimposed loads bearing on it. The supported wall in this case is carried up as one solid bonded piece of brickwork, and not cut up into rectangular sections as in a steel-frame building; horizontally by girders at each floor level, and vertically by the steel stanchions in the piers between the windows, the only steelwork required being small lintels over the window heads.

Supposing a case such as the front wall of a shop, in all probability the wall above the first-floor level is sufficiently

* Previous articles appeared on January 8 and January 15.

† Since the above was written the proposed alterations to the London Building Act have been published, dealing with the steel skeleton framework for buildings. If these become law it will be an evenly balanced question whether any substantial economy will be effected by employing the steel-framed structure (even though the walls may be reduced in thickness) in place of the ordinary method, which is governed by the original Building Act. The restrictions, especially that one relating to the deposit of the plans and details a month previous to the commencement of the building, are likely to nullify any advantages that this system possesses. Moreover, but slight advantage is obtained until the number of storeys runs into double figures, and apparently the limit in this respect has not been covered by the proposed new portion of the Act. Consequently "the old order changeth, giving place to new," may not apply to any great extent.

Digitized by Google

strong of itself to carry its own weight and any floor girders that may rest upon it. The English practice would be to carry that wall on one large girder at the first-floor level, supported on stanchions extending from the basement to that floor level. In the case of a steel frame these stanchions would extend up to the girders carrying the roof; in either case the loads, and therefore the sectional areas of the stanchions in the basement and ground floors would be the same; but the upper stanchions may be said to be worse than useless.

Again, one large girder or bressummer is far more economical than several smaller ones; a small amount of steel area in the flanges of the large girder would accomplish what would require a considerable amount in rolled steel joist sections.

The same argument applies even more forcibly to internal walls; it is perfectly absurd to carry the enormous masses of brickwork on a steel framework of stanchions and girders at each floor level when these walls are amply sufficient to carry all that is required of them from the top to the footing courses at the foundations.

There is one feature that is very important in English, and rarely met with in American, large buildings. The Englishman must have his fire and fireplace, whereas the American requires steam heating and radiators. Chimney-stacks are immensely heavy; in fact, unnecessarily so; and something might be done in the way of lightening their construction, especially, as often happens, in cases where the stacks are carried on girders. The steel-frame designer is inclined to carry his theory too far in placing the steel girders that carry the chimneys at each floor level; this is surely most undesirable. Apart from the fact that one large girder is more economical than many smaller ones, the splitting up of the chimney-stack into sections destroys its uniformity of structure, and any slight shrinkage or settlement may result in cracks opening in the brickwork of the flues, which may be, and indeed have been, the cause of annoyance from the smoke leaking through them.

In some cases this has occurred, and the fault attributed to the deflection of the supporting steel girders, whereas undoubtedly this was due to the mortar, in which the cement had been too "hot"—i.e. fresh from the kilns—or had been mixed with lime, the result being that the mortar in the 9-inch internal wall between the two sets of flues had set and expanded after that in the 4½-inch external walls, causing by its lifting action horizontal cracks to open on the face of the chimney-breast.

Another instance may be cited to show that the steelwork is often made the scapegoat for the sins of other materials. A certain building was erected on a steel framework at the first-floor level, the ground floor being a yard, entirely open except for the columns supporting the building over it. For a year or more after the building was finished the walls of the upper storeys seemed to be alive; cracks were appearing and closing up in an extraordinary manner. Of course, the steelwork was considered to blame, and experts were called in to solve the mystery. Girders were tested for deflection, but evidently this was not the cause of the movements that were still going on. Then some inquiries were made in regard to the mortar, which discovered the fact that a large quantity of plasterers' refuse had been ground up in the mortar mill, and so the culprit was revealed.

(To be continued.)

The Trustees of the National Galleries of Scotland, in order to increase their usefulness, have decided to lend certain works of art, of more recent acquirement, to the art galleries in Glasgow, Aberdeen and Dundee for a period of three months.

Mr. J. W. Allen, M.A., will give a course of six lectures on "English Mediæval Architecture" on Fridays, at 4.30, at Bedford College for Women, York Place, Baker Street, W., beginning on Friday, February 5. The course will be illustrated by plans and photographs. The course will be free to students of the University and to teachers on application to the Principal.

The Carpenters' Company have arranged for a series of lectures on the following subjects:—"February 11, "The National Gallery," by Mr. M. H. Spielmann; February 18, "Armour," by Lord Dillon; February 25, "Design and Craft in English Woodwork," by Professor Beresford Pite; March 4, "Architecture of Hampton Court," by Mr. Ernest Law; March 11, "Ancient Buildings and their Influence on Modern Architecture," by Mr. Thackeray Turner; March 18: "Timbers of Commerce: their Present and Possible Future Sources of Supply," by Mr. H. J. Elwes.

THE WORKMEN'S COMPENSATION ACT (1906) IN OPERATION.—III.

By W. S. HOLDSWORTH, D.C.L.

Questions Relating to the Rights of Dependants.

DEPENDANTS are defined in section 13 of the Act to mean "such of the members of the workman's family as were wholly or in part dependent upon the earnings of the workman at the time of his death, or would but for the incapacity due to the accident have been so dependent." Moreover, it includes illegitimate children or grandchildren, or the parents or grandparents of such illegitimate children or grandchildren. Under the provisions of schedule 1, section 1, these dependants have a definite right to compensation which is distinct from the right of the deceased workman. Thus their right cannot be waived or abandoned by him; and if the dependant die before the amount of the compensation is ascertained the right to receive it passes to his or her representatives. These consequences of the rights given by the Act have been clearly laid down by the Court of Appeal in the two following cases.

In the case of Williams *v.* Vauxhall Colliery Company, Ltd.,* the facts were as follows:—Williams was a collier in the employ of the defendant company. He received an injury in the course of his employment, and made an arrangement with the defendants as to the amount of the compensation due from them. After a year's illness he went back to work, nothing having been said as to the continuance or cessation of the compensation. He was still suffering from the effects of the accident, and some time after died from acute mania brought on by it. The Court of Appeal held that there was no evidence of any agreement to abandon all further rights to compensation. Moreover, even if there had been such an abandonment on the part of the workman, it could not affect the rights of his dependants. They had a separate and distinct right of which the workman could not deprive them, subject, however, to this, that the employer from first to last could not be bound to pay more than the maximum provided by the Act. Thus the employer can take credit for all sums actually paid to his deceased workman, and is liable only for the balance due to his dependants in case of his death. In the case of Darlington *v.* Roscoe & Sons† the deceased workman left one dependant—a widow. She made a claim for compensation, but before the case had been arbitrated upon she died. Her daughter as her administratrix then began proceedings for arbitration under the Act, and the Court of Appeal held that she was entitled to do so, and to claim the sum to which her mother was entitled. The Act gives a personal right to the dependant to receive the sum mentioned in the schedule. That right descends, like any other property, to her representatives. But it should be noted that the right in question depends upon the fact that the claim has been made. Therefore if a dependant dies before a claim is made there is no right to be transmitted.

No doubt these cases are sound constructions of the words of the Act. But, looking at the last-mentioned case, it is perhaps arguable that the Act has gone rather too far. It may be just that a workman shall be compensated. It may be just that certain persons who can be shown to be dependent on him shall be compensated. It is a little difficult to see why the employer should be obliged to pay a sum of money to persons who are not dependent. If the dependant had lived to enjoy the money, that money would have been doubtless spent in maintenance; it would be very unlikely that any considerable sum would have come to the personal representative. It would be more just and more in accord with the general scheme of the Act if the law were changed in this case, and if it were provided that compensation money not actually ascertained and paid over to a dependant should cease to be payable if that dependant died.

Questions have arisen as to the meaning of the terms "total and partial dependency," and as to the circumstances in which the *primâ facie* presumption of a wife's dependency on her husband may be rebutted. In both these cases the Court has laid down rules which seem to give a very wide, perhaps some would say an unduly wide, meaning to the terms of the Act.

In the case of Senior *v.* Fountains & Burnley, Ltd.,‡ the

Digitized by Google

widow of a workman who had met with a fatal accident claimed compensation on behalf of herself and three children, aged six, ten, and thirteen. The deceased at the time of his death was also receiving the wages of other children, aged nineteen, seventeen, and fifteen. The father boarded, lodged and clothed these wage-earning children, and gave them pocket-money. The County Court Judge found that this arrangement was a source of profit to the father, so that at his death the family was supported partly by the father's, partly by these children's earnings. He considered that the income derived from the sons could not be considered to be the father's earnings, and he therefore decided that the wife and children were not wholly dependent on the father's earnings. The Court of Appeal reversed this decision, holding that a wife and children are not the less wholly dependent upon the earnings of a father because the father has been able from other sources to augment the fund from which he maintains his family. It is true that the House of Lords has decided * that where a wage-earning son, who contributed to the support of his father, was killed in an accident, the father could maintain a claim for compensation as being in part dependent on his son's earnings. The Court of Appeal held that this case was distinguishable on the ground that, whether or no the father got money from other sources, his family were still wholly dependent on him. In fact, the only case in which it could be said that his family were not wholly dependent upon him was the case where wife or child had a separate income apart from the father. It seems to us that the fallacy in the judgment of the Court of Appeal consists in a confusion between the legal dependency of the family on the father and dependency on the earnings of the father. The Act talks of total or partial dependency, not on the father, but on his earnings; and if the father partly maintains his family from his earnings and partly from other sources, it would seem that the family cannot be considered to be wholly dependent on his earnings.

In the case of Williams *v.* Ocean Coal Company, Ltd.,† a widow claimed compensation in respect of herself and a child *en ventre sa mère* at the time of the accident to her husband. Her deceased husband had deserted her, and throughout their married life she had seen very little of him, living for some short time with his parents, but for the greater part of the time with her own parents. The County Court Judge held that the wife was not dependent on her husband's earnings. The Court of Appeal overruled this decision. They held that in the case of husband and wife there was always a presumption of dependency. It might be rebutted, but it was not rebutted by the mere fact of desertion, or by the fact that the husband was not contributing to his wife's maintenance. It would seem to follow that if a husband deserts and neglects to maintain his wife the best chance the wife has of getting anything from the conjugal relationship is the chance that her husband may get himself killed by a fatal accident while in the service of a solvent employer. As a matter of law the decision is doubtless right; but it would seem that the Court has been compelled to decide in accordance with technical legal doctrines in such a manner that the spirit of the Act has been lost. Dependency in fact, and not dependency deduced from legal presumption, should give rise to compensation; and no doubt if the hardship weighed on the workman rather than the employer an amending Act could be passed to remove it.

In general the Act, as interpreted by the Courts, has effected what it was intended that it should effect. The Courts have decided in accordance with the plain sense of words and the underlying intentions of the Legislature. They have not allowed themselves to be fettered by presumptions and technicalities. But in some of those cases relating to dependants the Act, as interpreted, seems to go a little beyond its proper scope, to give greater benefits to the workman, and to put a greater burden on the employer than is consistent with its scheme of compensation.

Liability for Certain Diseases.

We have seen that in general a workman who is killed by a disease, even though that disease was contracted in the course of his employment, cannot be said to have been killed as the result of an accident.‡ But, as is well known, certain diseases are incident to certain trades. The Act, section 8, provides for this contingency by enacting that if a workman is incapacitated from work, or dies, owing to having contracted any of the diseases mentioned in the third schedule of the Act, or others to be added by the Secretary of State, he or his dependants shall be entitled to compensation as if the disease were a personal injury by accident arising out of and in the course of his employment. The effects of this section have been discussed in the case of Haylett *v.* Vigor & Co.* In this case the deceased workman was a painter who died of granular kidney. This disease is a sequela of lead poisoning, but it is also a sequela of other diseases, such as gout or alcoholism. As the claimants could not prove that the man died of lead poisoning, but only that he died of a disease which might or might not be a consequence of lead poisoning, it was held that their claim failed. The onus of proving death by a scheduled disease is on the claimant. If death by the scheduled disease of lead poisoning had been clearly proved, then, in accordance with section 8, sub-section 2, of the Act, the onus of proving that the disease was not due to the nature of the employment is on the employer, unless the certifying surgeon certifies that it was not so due.

(To be concluded.)

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

The following gentlemen were elected members:—Messrs. E. L. Apperly, O. Newbold, H. Boyd-Walker, C. J. Newberry, B. H. B. Symons-Jeune, T. H. Chalkley, A. C. Newman, J. B. L. Tolhurst and A. Thorpe.

Mr. J. H. MARKHAM read a paper entitled—

Reinforced Concrete.

You are probably aware, he said, that when I was first asked to read a paper on reinforced concrete it was to have been more especially with reference to design—that is, I presume, the character of artistic expression suited to this method of construction. I rashly undertook to do this; but in attempting to get together matter for illustration and example I found the question of the proper artistic treatment had very seldom been fairly tackled in building work of a kind usually within an architect's practice. A good deal of simple straightforward engineering work has been done which, I think, is often of pleasing appearance when not spoilt by any pretence to be other than it is. But when buildings such as an architect is accustomed to deal with have been undertaken in this method of construction, the front has generally been built of brick or stone and the reinforced concrete part all been hidden, as would have been the case with a steel frame. This has compelled me to take up the chief features and principles of this method of construction, and try to deduce therefrom some ideas for the right treatment of it.

To get out of my difficulty I have decided to assume you know nothing about reinforced concrete; so that I shall deal briefly with the subject in a general way, and I must apologise if I go over what will be familiar ground to many. I will begin by briefly describing the materials used, viz. concrete and steel.

Taking concrete first, concrete is composed of a matrix or cementing material and an aggregate.

The matrix used in reinforced concrete work is Portland cement, and must be of the best possible quality. Limes are not suitable, as they are at best of imperfect hydraulicity—that is, their power of setting when air is excluded is but small and variable, and they are of less ultimate strength than cement. The cement should be frequently tested, as so much depends on its quality. Portland cement is an artificial compound, obtained by calcining lime and clay in proper proportions and grinding the resulting clinker. After much experience and experiment it can now be obtained of very high quality, and on no account should limes, or natural cements, or an inferior Portland cement be substituted.

It is essential that the aggregate be composed of a material which does not contain acids capable of corroding the metal, and for this reason coke breeze and furnace slag must be used with caution, if at all. The best materials are crushed ballast, broken brick, granite chippings and broken stone, though limestone cannot be recommended where great fire-resisting qualities are required. No particles should exceed ¾ inch in diameter unless where the reinforcement

* 24 T. L. R. 885.

Digitized by Google

is spaced further apart than usual, otherwise they will not be able to pass easily between the reinforcements, so that there may occur voids in the finished work; and it is desirable that particles be not all of the same size, but varying from ¼ inch to ¾ inch, so that the smaller particles may fill up the interstices between the larger. Material having grains less than ¼ inch diameter is known as sand, and a certain proportion of clean sharp sand, free from loamy or organic matter, is used to form with the cement a mortar which shall surround each particle of the ballast or stone, and so unite all the particles and as far as possible fill up all the voids so that the whole may be a solid compact mass.

A good proportion in which to mix the ingredients of the concrete is one part of cement to two of sand to four of ¾ inch ballast measured by bulk. This does not mean one of cement to six of aggregate, because when the sand and ballast are mixed the sand fills up some of the interstices in the ballast, and the whole comes to about one of cement to four and a half of aggregate. This should be carefully noted, because at first one is inclined to think one of cement to two of sand and four of ballast is equivalent to one of cement to six of aggregate, but it is in reality a good deal richer.

It is essential that the ingredients be in such proportions that the sand and cement fill up the voids in the ballast so that the smallest possible percentage of air spaces may exist in the resulting concrete. Concrete cannot be obtained absolutely free from air spaces.

The steel used is mild steel of good quality. The specification of it I need not repeat; it is to be found in the report of the Committee on Reinforced Concrete, published by the R.I.B.A. It is usually employed in the form of round rods from 2-inch or sometimes 2½-inch diameter down to wire; and some systems use also a flat section like hoop iron, as in the Hennebique shear stirrup. Other systems have special deformed bars—but of that more later.

I need scarcely point out that a great advantage of reinforced concrete is that in almost any district suitable materials can be found near at hand. Cement is made in all parts of the country; and Mr. Kahn pays a very high tribute to the quality of British cements in a paper read before the Institution of Engineers and Shipbuilders in Scotland, in which he says they are probably the best in the world, fully 100 per cent. better than American and many times better than Belgian.

A suitable aggregate should not be far to seek anywhere, and even if the steel has to be brought some distance it is only about 20 per cent. of what would be necessary in a steel-frame building, and would always be of small section and easily handled.

Having briefly described the materials employed, it remains for me to say a few words as to the reasons for combining two materials so essentially different. Concrete, as you know, is a comparatively inexpensive building material, and, when well made of suitable ingredients, capable of withstanding considerable compressive stress and offering resistance to fire. Steel and wrought iron, on the other hand, are expensive and of great strength in both compression and tension. Well, now, the notion arose of combining the two, so that steel might be used to resist all tensile stresses and the cheaper concrete might be used to resist all compressive stresses and provide a protecting covering for the metal.

So far so good; but now a difficulty arises in one's mind. We all know the disastrous effects of iron cramps used in stonework when insufficiently protected from the action of the weather, so that it is essential that all metal used be absolutely covered to prevent the action of the atmosphere thereon. But will the moisture of the concrete and the acids of the cement corrode the metal? This is a point of all importance, and there are many interesting facts and tests which are too numerous to recount, but which in the main go to prove that, so far from the cement having any harmful effect on the metal, it not only preserves it from rust, but if the metal have a little rust on the surface when inserted in the concrete, the rust is removed, and the metal, if afterwards withdrawn, will be found bright and clean, and moreover less liable to rust than a piece of metal which had not been in contact with cement. The explanation of all this is an interesting question for chemists, but the facts serve to show that no better preservative can be found for steel than cement. It is of course known that the steel is not painted or otherwise treated before being used. No loose scales of rust must be allowed, but a slightly rusted surface is rather an advantage, as it assists the adhesion between the metal and concrete.

I should add that if from any cause cracks occur in the concrete, then water may get in and the metal become oxidised.

If there is any fear of small quantities of water penetrating the concrete and coming in contact with the metal, then it would be advisable to cover the bars before use with a coating of cement grout, so that they would be completely covered by cement even if the concrete should prove a little porous. It should also be mentioned that a few cases have been cited of metal corroding without any apparent cause, but such cases are few and probably could all be accounted for by some causes other than the failure of concrete, when properly made and not cracked, to preserve the metal. The general inference from all the information I have come across is pretty much what I have stated.

I will now come more particularly to my professed subject, viz. design. And in dealing with design I shall divide my remarks into three main heads:—

1. What I shall call "internal" design.
2. Main structural lines and forms.
3. Decorative design and finish.

A great peculiarity of reinforced concrete is that not only, as with other better-known materials, is it necessary to decide on the size a member must be, but it is also necessary to design the internal structure of the member itself. In fact, it is necessary to design the material as well as the building.

In using steel or wood, a member of certain size and section is found necessary, and it consists throughout of the same steel or wood of known, and practically uniform, strength; and all members of the same size and section will be approximately of the same strength. However, the strength of reinforced concrete members of any given size and section may vary within very wide limits, according to the percentage and disposition of the metal, even where the strength of the concrete and steel may be constant. It would be possible to introduce, say, 1 per cent. of metal into a concrete beam without in any way strengthening it; and it would also be possible to introduce 1 per cent. of metal in such a way as to very materially raise the moment of resistance the beam could offer. It is not quite my province tonight to deal with this question of internal design, which is a very large subject, as there are many systems, some of them covered by patents, which make it somewhat awkward for a designer to make use of the method of reinforcement he may consider most suited in each particular kind of member. However, I propose to briefly go over the principles.

As I have already stated, the general principle is to use steel to resist all tensile stresses, and to provide against the tendency to shear, whereas concrete is used as far as possible to take all purely compressive stress. That means to say that, in the case of beams, metal reinforcement will be found imbedded in the lower part, whereas the upper portion will be of concrete. If, however, as is usually the case in reinforced concrete buildings, beams are continuous over two or more spans, then a reverse bending moment occurs over the supports causing the upper side to be in tension, and the lower in compression, so that here the reinforcement comes in the upper part of the beam. It may, of course, be advisable to introduce reinforcement in the compression area of a beam as well; but I will not speak further of that, as I am only giving a very general statement of principles, leaving all matters of detail, and description of peculiar cases, for lack of time. I would only say as to this before passing that, if compressive reinforcement is introduced, it is a departure from the ideal that all metal should be always and only in tension, and all concrete always and only in compression. But this ideal has to be often departed from, and for practical reasons it is often necessary to put metal in the compressive area. M. Coignet does so regularly. The concrete occurring in the portion subject to tensile stress is ignored in calculation, as it is not permissible to rely on concrete for resisting tensile stress even in the smallest degree.

Tendency to shear is resisted by steel members, loose in the form of hoop steel or round section stirrups, or rigidly attached to the tensile reinforcement, placed either vertically or obliquely.

For tension members, in a truss form, to conform to our ideal no concrete should be used. However, concrete must be used to cover and protect the metal, no more being introduced than is necessary for this purpose; and it must not be reckoned in the calculation. In the same way, it would seem at first that no steel should be used in compression members, but on consideration we shall see that it may be to advantage without any serious infringement of our ideal. Suppose a compression member—say a column—of concrete supporting a load. The tendency of the load is to produce a reduction

Digitized by Google

in the length of the column; and, as matter is only slightly compressible, there will be a tendency for the material to find compensation for this shortening by enlarging in another direction This enlarging will take place where it meets with least resistance, that *is*, in planes at right angles to the direction of pressure; in the case of a column, horizontally. This tendency to enlarge horizontally, that is to spread, will tax the cohesive strength of the outer portion of the column; in other words, there will be a circumferential or hoop tension. But it is not desirable to submit concrete to tensile stress, and as it would seem that some small hoop tension will always be produced in a compression member, because there will always be at least a tendency to diminish in length under the applied load, some form of metal case seems called for, which shall be capable of taking up the circumferential tension, and so prevent lateral spread. Assuming this to be done, we have a member in which our ideal is satisfied. The hypothesis that concrete must not be relied on to resist tension, traced to its logical end, is tantamount to an assumption that concrete is possessed of no cohesion; so that our ideal column becomes analogous to a steel sylinder filled with some such material as fine sand. In such a member, the sand obviously could not be crushed, and after taking such slight reduction in volume as the pressure could produce, its power to resist unlimited pressure would seem to depend only on the capability of the containing cylinder to resist the hoop tension, and the shearing stress. Now, to return to our concrete column; as concrete does possess cohesion, the cylinder may be replaced by hoops at frequent intervals, or by a spiral binding, and to further prevent the tendency to spread, by bulging between the hoops or spirals, let us introduce a few longitudinal bars just inside the hoops to form with the hoops a sort of containing network. These longitudinal bars can also be relied on to resist the shearing stress which accompanies compression and tension stresses on planes oblique to the axis of the main stress. This method of reinforcement, which seems to me theoretically ideal for compression members, has been mainly developed, and several remarkable properties thereof discovered by M. Considere However, the other systems of reinforcement follow much the same principle in column design.

I would only just further mention on this question of internal design, that the patent systems just referred to are of two main kinds:—

1. Those in which the patent is for a particular arrangement of reinforcement.

2. Those in which the patent is for a special form of reinforcing bar.

This second class, again, has two sub-divisions:—

(*a*) Those bars which are of peculiar form to lessen the tendency for the metal to slide in the concrete.

(*b*) Those bars which have rigid or loose attachments to resist shear.

As to adhesion between metal and concrete, it has been stated—based, I suppose, on experiment—that a bar immersed in concrete for a length equal to fifteen times its diameter, will, if it be attempted to drag it out, break rather than slide out. If so, it would scarcely seem necessary to have recourse to any special deformation which must slightly increase the cost, unless there is some influence specially likely to produce rupture of the adhesion. In the Hennebique system, bars are fish-tailed at their ends in case there should be any tendency to slide.

Among bars deformed to resist sliding may be mentioned Ransome's twisted bar, a square section twisted; and the indented bar. The Ransome bar, which, so far as I know, has only been used in America, is twisted cold, and it is claimed by those who use it, that it is of much greater strength than a round bar of similar steel, which has not been twisted, so that less metal has to be used. The indented bar is now in use in this country, as well as America, and is sold by the Patent Indented Steel Bar Company, of Westminster. The system of reinforcement with these bars is the same in principle as that where round rods are used, as, of course, all systems meet with, and are controlled by, the same dynamic laws.

Of the bars with shear members attached, the best known is the Kahn bar; and mention must also be made of the Wells bar used by Stuart's Granolithic Company; it is of a section somewhat resembling two round bars connected by a very small web, shear members being of hoop metal threaded through a slit in the web. But I must leave this part of my subject.

(*To be concluded.*)

ARCHITECTURAL REFINEMENTS.*

UNDER the term widening refinement is understood a hitherto unnoticed but widespread system of mediæval church and cathedral construction in which the vertical lines of the nave diverge in the upward direction. The announcement of such a system of intentional construction has been met by the denial of its existence on the part of many distinguished experts, especially in France. Such experts presume the facts to exist but attribute them to accident, and more especially and exactly to accidents caused by the thrust of the nave vaulting. The proofs of an intentional construction are however many and serious. They are presumed by Mr. Goodyear to be conclusive, and have been so recognised by the architect in charge of repairs in Rheims Cathedral, by the master-mason of the same repairs, by the architect in charge of the repairs of Amiens Cathedral, and by many distinguished experts in construction, among whom may be mentioned Professor A. D. F. Hamlin, of the Columbia University Architectural School. The monuments examined, and supposed to offer these conclusive proofs, include a large number in Italy, a large number in Northern France and other churches in Constantinople. The demonstrations from these buildings are universally and without exception submitted in the form of enlarged photographs which are exhibited in the Museum of the Brooklyn Institute of Arts and Sciences. These photographs are presumed not only to illustrate the facts of widening, which they undoubtedly do, but they are also presumed to offer such a choice of facts as to negative the theory of accident. The widening refinement includes many cases of widening in straight lines, and these cases are more easily shown to be constructive than those in which the widening occurs in vertical curves. The demonstration of the present paper does not debate the vertical curves. It is confined to the cases of widening in straight lines.

There are two phases of widening in straight lines, piers which incline outwards from the pavement up, and piers which are perpendicular to the capitals; with vaulting-shafts which diverge in straight lines, beginning at the capitals. To the former class belong, among other churches, St. Alpin at Chalons, St. Loup at Chalons, St. Ouen at Rouen, and the cathedral of Rouen. To the latter class belong, among other churches, the cathedral of Rheims, the cathedral of Amiens, the cathedral of Laon, and St. Remi at Rheims.

If the widening refinement were due to thrust, in the case of churches with piers which lean out from the pavement up or with shafts which lean out directly above the capitals the lines would bend or curve above the counter-thrust and weight of the side aisles. Since resistance to the nave thrust decreases in the upward direction, accidental widening in straight lines against the weight and counter-thrust of the side aisles is not to be assumed as likely or possible, even in a single instance. The possibility of a subsidence of the exterior lower walls of the churches appears to be the only one which even in theory could explain an accidental widening of the kind described and observed. If such subsidence had taken place at Rheims or at Amiens it would be known to the experts in charge of repairs.

Constructive stability is not endangered by the system discussed. At Amiens the lean outward is less than one-seventh of the diameter of the pier, and at Rheims the piers are far heavier than at Amiens, whereas the maximum inclination is the same.

It seems probable that the counteraction of an optical narrowing in, or spindling effect, due to perspective convergence, may have been one purpose of the widening refinement. But it seems also probable that this refinement is the expression of a positive artistic preference, based on experience and on good taste, for a diverging effect in the vertical supports of an arch.

The preference, or liking, on the part of the Arab builders for the horseshoe effect in arches may be a related fact, and there is an undeniable relation to the form of the horseshoe arch in this construction, but without that inward bend at the base which, to some of us, is its disagreeable feature.

The widening refinement dates to the sixth century at Constantinople, and it disappears with the overthrow of the Gothic style by the Renaissance in the sixteenth century. This overthrow was so complete that even the existence of the refinement has been forgotten.

* A synopsis of a paper read at the Toronto meeting of the Archæological Institute of America on December 29, 1908, by Mr. Wm. H. Goodyear, "On the Recent Observations of the Widening Refinement in Amiens Cathedral."

NOTES AND COMMENTS.

MANY of our readers, we believe, were interested in the articles on "Petrography for Architects," by Mr. E. HOWARD ADYE, that appeared in *The Architect* of January 3 and January 24, 1908. They will find in the current number of "The Engineering Magazine" an equally interesting account by Professor JACQUES BOYER of Microscopic Metallography and its employment in French industries. In this are described some of the latest developments in microscopic analysis and examination of materials, more particularly with regard to metals, together with a description of the methods and apparatus employed. In building materials strength and durability depend largely upon physical structure rather than chemical composition, and microscopic analysis is a most useful method in the examination of physical structure. One must not, however, allow enthusiasm for this method to outrun sober judgment and lead us to altogether discard the old. Indeed, we cannot do better than quote Professor BOYER's conclusion:—"It must be conceded that the new processes complete most usefully the knowledge supplied by chemical analysis or by mechanical tests, but cannot supplant all the other methods of examination, either in the laboratory or in the shop."

SUPERSTITIOUS traditions die hard, luckily for novelists; but one of hoary antiquity, whose origin it is not difficult to predicate, receives a severe blow from the statistical investigations of Mr. FRANCIS GALTON. This well-known scientist, by way of amusement, has examined the veracity of the legend that possession of sequestrated Church property entails a curse on some eldest son of the sequestrator's descendants. Tracing the history of a large number of former Church properties and comparing it with that of purely secular domains, the investigator found that the succession of eldest sons was in the case of sequestrated Church properties only 1 per cent. less than in that of those not under the traditional ban. True that the former priories and their kin came into the market and changed hands three times as often as the unhallowed estates, but this is probably due to the insanitary and uncomfortable condition of ancient ecclesiastical residences, which are apt to be more picturesque than pleasant in the light of modern ideas. The moated grange, with its water supply drawn from one side of the moat, its sewage discharged into the other, and the fish for Friday's dinner swimming between, is scarcely what we nowadays consider hygienic. Damp courses in mediæval buildings are not always of adequate efficiency, with the result that rheumatism, ague, and other unpleasant afflictions are more than likely to be connoted. It would be interesting if Mr. GALTON were to compare the history, as regards change of ownership, of moated granges with that of moated manor-houses, which, as regards their relative attractiveness and disadvantages, are very much on a par.

THE latest "Red Book" issued by the British Fire Prevention Committee is a report of a test held so long ago as July 28, 1904, the issue of which "was postponed for special reasons by order of the Executive." The report deals with one of the many varieties of thin partitions formed with slabs, of which plaster of Paris is the principal ingredient. In this case, the Brunckhorst partition slabs were composed of plaster of Paris and coke breeze in equal proportions. The slabs have a peculiar form of grooved and serrated edge, and as erected into a partition by Messrs. H. GUST & Co., were strengthened by wire reinforcement in both horizontal and vertical joints. The object of the test appears to have been to ascertain if this particular partition should be classified in Class A by the B.F.P.C. as affording "partial protection." The report does not state whether the partition is so classified, but, in our opinion, the result of the test was quite satisfactory for this class of fire-resisting partition.

PART I. of the fourth volume of "Architektur-Konkurrenzen" contains illustrations of the six premiated designs submitted in competition for a new Kurhaus at the watering-place of Zoppot. With the Kurhaus are included a boarding-house with 100 rooms, concert and beer-gardens, the laying-out and equipment of which forms part of the problem. The scale of the original drawings being $\frac{1}{250}$, or rather smaller than our one-sixteenth scale, no attempt at showing detail is made, the scope of the competition being clearly limited to planning and general composition. The plans are well worked out in detail, but the elevations and even the perspectives are purely sketches. As appears to be quite common in Germany, the first and second premiums are added together and divided equally by the jury between two competing designs.

THE New Year number of *The American Architect* marks the incorporation with it of the *Inland Architect* and is remarkable for the illustrations it contains of the library of Mr. J. PIERPONT MORGAN, a laudatory article on which appeared in the *Times* of December 4 last. The building, designed by Messrs. MCKIM, MEAD & WHITE, is a fitting home for the priceless treasures collected by Mr. MORGAN. The Free Christian Church, Andover, Mass., also designed by Messrs. MCKIM, MEAD & WHITE, might have been built in the lifetime of the Countess of HUNTINGDON, so reminiscent is it of the spirit of English and therefore of "Colonial" architecture at the time when the "Connection" of that remarkable personality was founded. By the way, Mr. CHARLES FOLLEN MCKIM is to be the second recipient of the gold medal of honour of the American Institute of Architects, the first being, as our readers will remember, Sir ASTON WEBB, R.A.

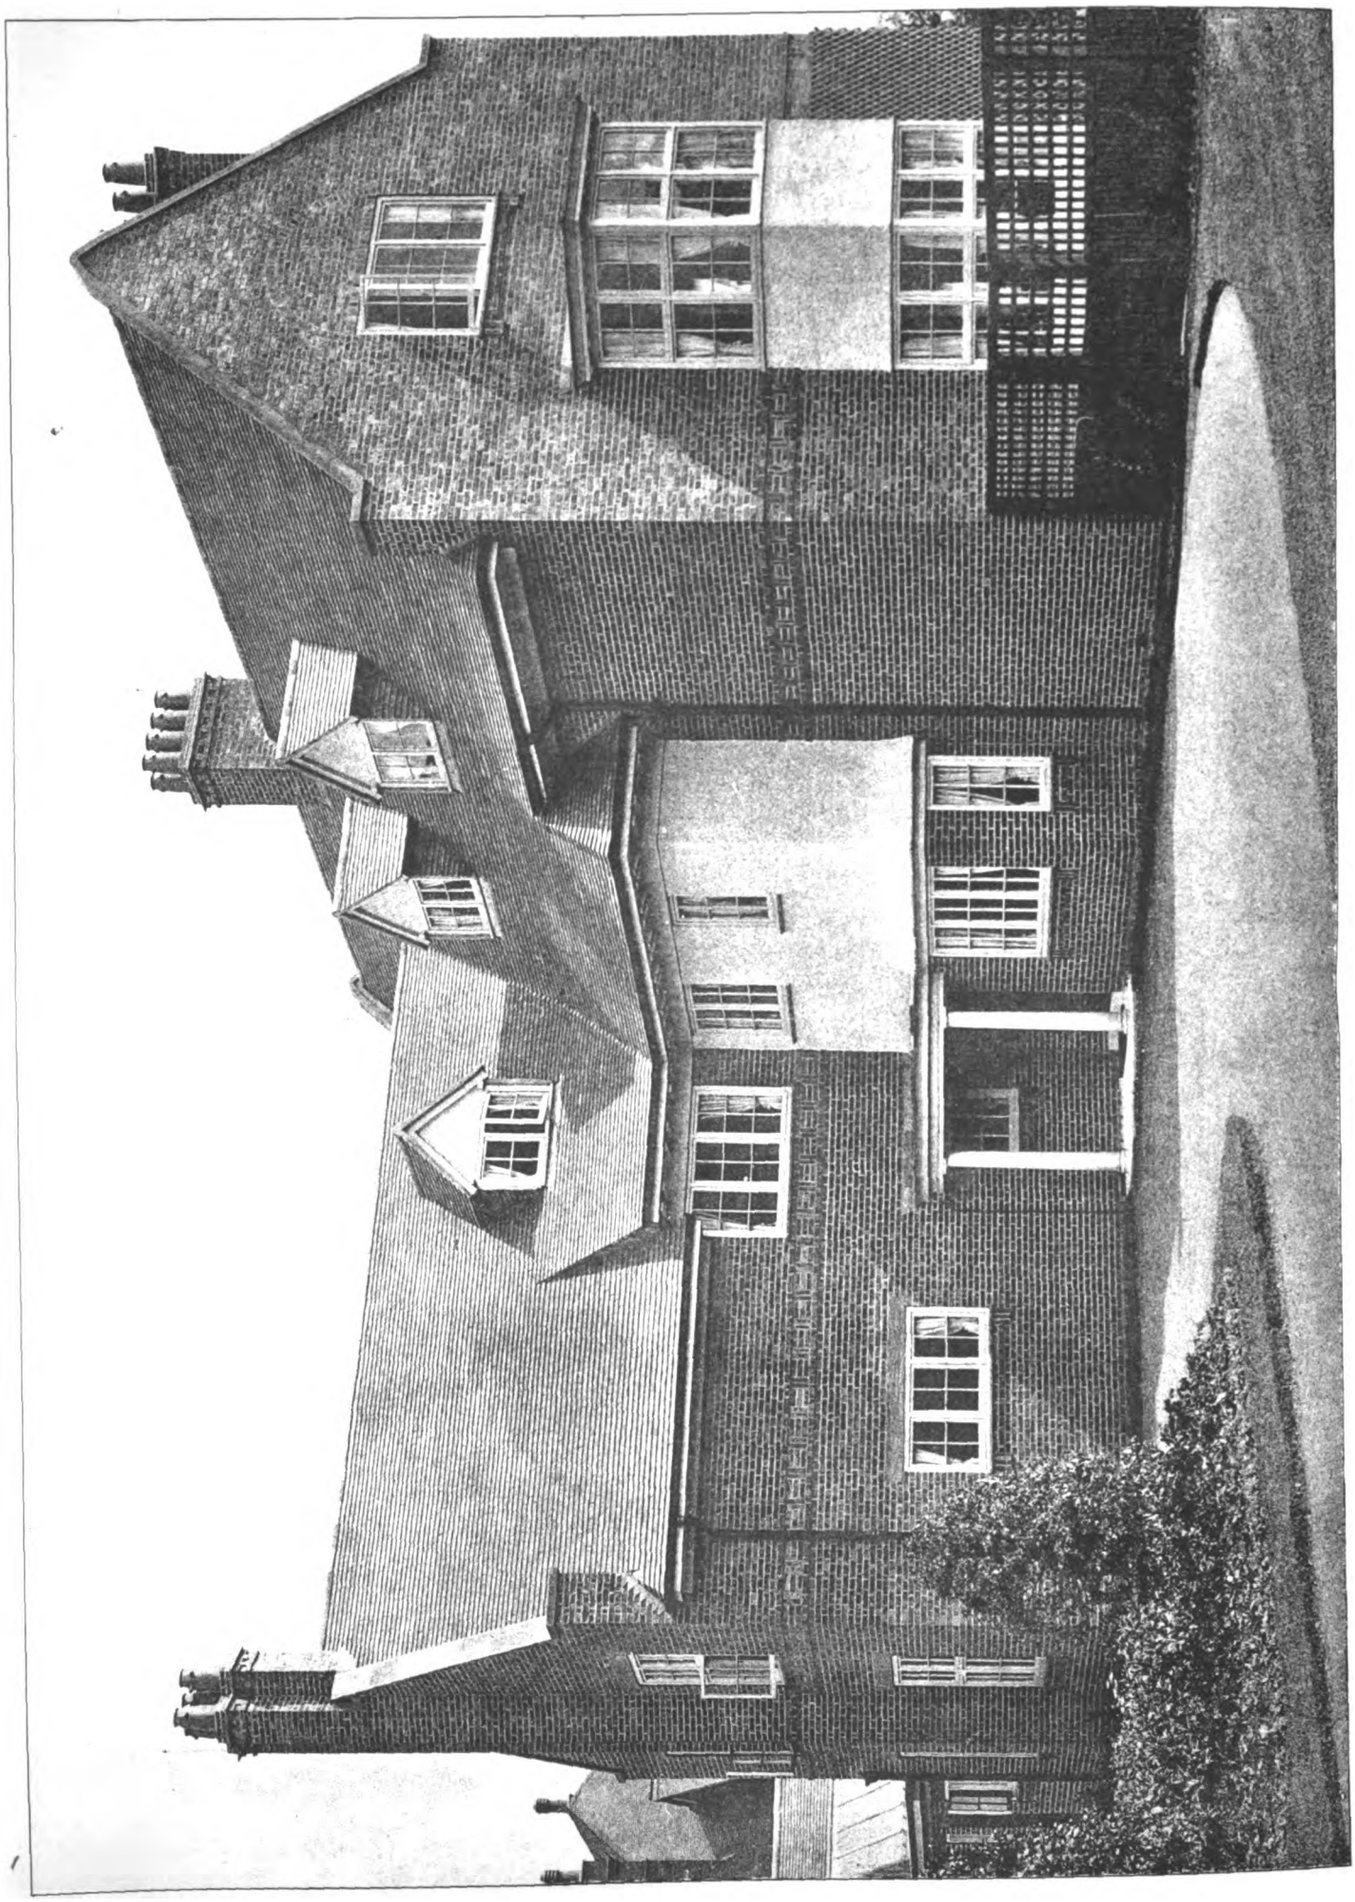
LIVING ARCHITECTS.—NO. 3, MR. JOHN BELCHER, R.A.



IN February 1907 it was announced at the Royal Institute of British Architects that the Council proposed to submit the name of Mr. JOHN BELCHER, A.R.A., to His MAJESTY as a fit recipient of the Royal Gold Medal. Mr. BELCHER, exactly two years afterwards, has now received the final and highest mark of approval from the world of art by his election, on Wednesday night, as a Royal Academician, after being an Associate for nine years. He will receive the congratulations of the entire body of architects, who cannot fail to be pleased at the dignity conferred on their profession in the election of one of their number to the coveted rank. Mr. BELCHER has been a student of the art from his early youth, when he was sent by his father, himself an architect, to Paris with instructions to pay particular attention to French Renaissance. His first experience was as an articled pupil, and then as a partner, to his father. During his long career Mr. BELCHER has designed many public and private buildings which have been a factor in the present position of architecture. We may mention the Institute of Chartered Accountants; Colchester Town Hall; Electra House, Moorgate Street; Lancaster Memorial; Royal London Friendly Society's Office, Finsbury Square; Royal Insurance Buildings, St. James's; Messrs. MAPPIN & WEBB's premises, Oxford Street; and among his mansions are Tapesley Park; Cornbury Park; Bearroc, in Berkshire; and Holcombe, Chatham. The dominant note in all this work may be expressed in Mr. BELCHER's own words:—"I have always aspired to do really good work, and particularly work which should embrace and include in its scope the sister arts of sculpture and painting." His election as a Royal Academician and the award of the Gold Medal are proofs of the attainment of his ideal. Literature has been another means by which he has endeavoured to educate the public, his last book, "Essentials in Architecture," being especially adapted to serve that end. Mr. BELCHER will, we hope, long continue to adorn the country with his art.

THE TECHNICAL INSTITUTE, EASTBOURNE.

THIS building was the outcome of an open competition, but the plans were largely altered from those placed first in the competition. This was partly due to the wishes of the donor of the site, the late Duke of DEVONSHIRE. To the town clerk, Mr. H. W. FOVARGUE, is due mainly the credit for carrying through this scheme. The floors are disposed as follows:—Ground floor, library and museum; first floor, boys' and girls' secondary schools and lecture theatre, with science rooms; second floor, art and caretaker; basement, technical work, as cookery, gymnasium, wood-carving, metal-work, bookbinding, &c., is intended to be carried on here, but this part is not completed yet. Mr. ANDREW CARNEGIE gave 10,000*l.* towards the library, which amounted to providing it. The contractor was Mr. F. G. MINTER, of Putney, and his tender 34,730*l.*; and the building was completed for rather less than this sum. The external materials are Whitbed Portland stone (worked on the site) and Keymer red bricks, and green Westmoreland slates from Tilberthwaite. The design was dominated necessarily by the size laid down by the Board of Education for art-room windows, which, of course, face north; and also by the fact that the Council rightly would not have drains on the main front, which necessitated the flanking towers containing the central manholes, in which are all the pipes. The various firms engaged were the Library Supply Company and LUCY & Co., for library fittings; Mr. BESSANT and Messrs. HENRY & Co., electric light and special fittings; the Acme Company, wood-block flooring; GEARY, WALKER & Co., mosaic terrazzo; WOOTON & Co., lead glazing; PILKINGTON & SON, ceramic work; ADAMSEY, Ltd., sanitary fittings; CHARLES SMITH & SONS, locks and gas fittings; the Bennet Furnishing Co., loose fittings; MERRYWEATHER & Co., hydrants and fire apparatus; J. & R. PEARSON, heating (low-pressure hot water); J. DAYMOND & SON, carving; J. LUCAS, lift; SMITH, WALKER & Co., steelwork; the Falkirk Iron Company, special railings. Mr. H. C. FEHR designed and modelled the charming groups on each side of the entrance, representing Science and Art and Literature. The clerks of works were Mr. HUDSON and Mr. R. HENLEY. The architect was Mr. PHILIP A. ROBSON, A.R.I.B.A., 9 Bridge Street, Westminster.

HOUSE AT EDGBASTON, BIRMINGHAM.

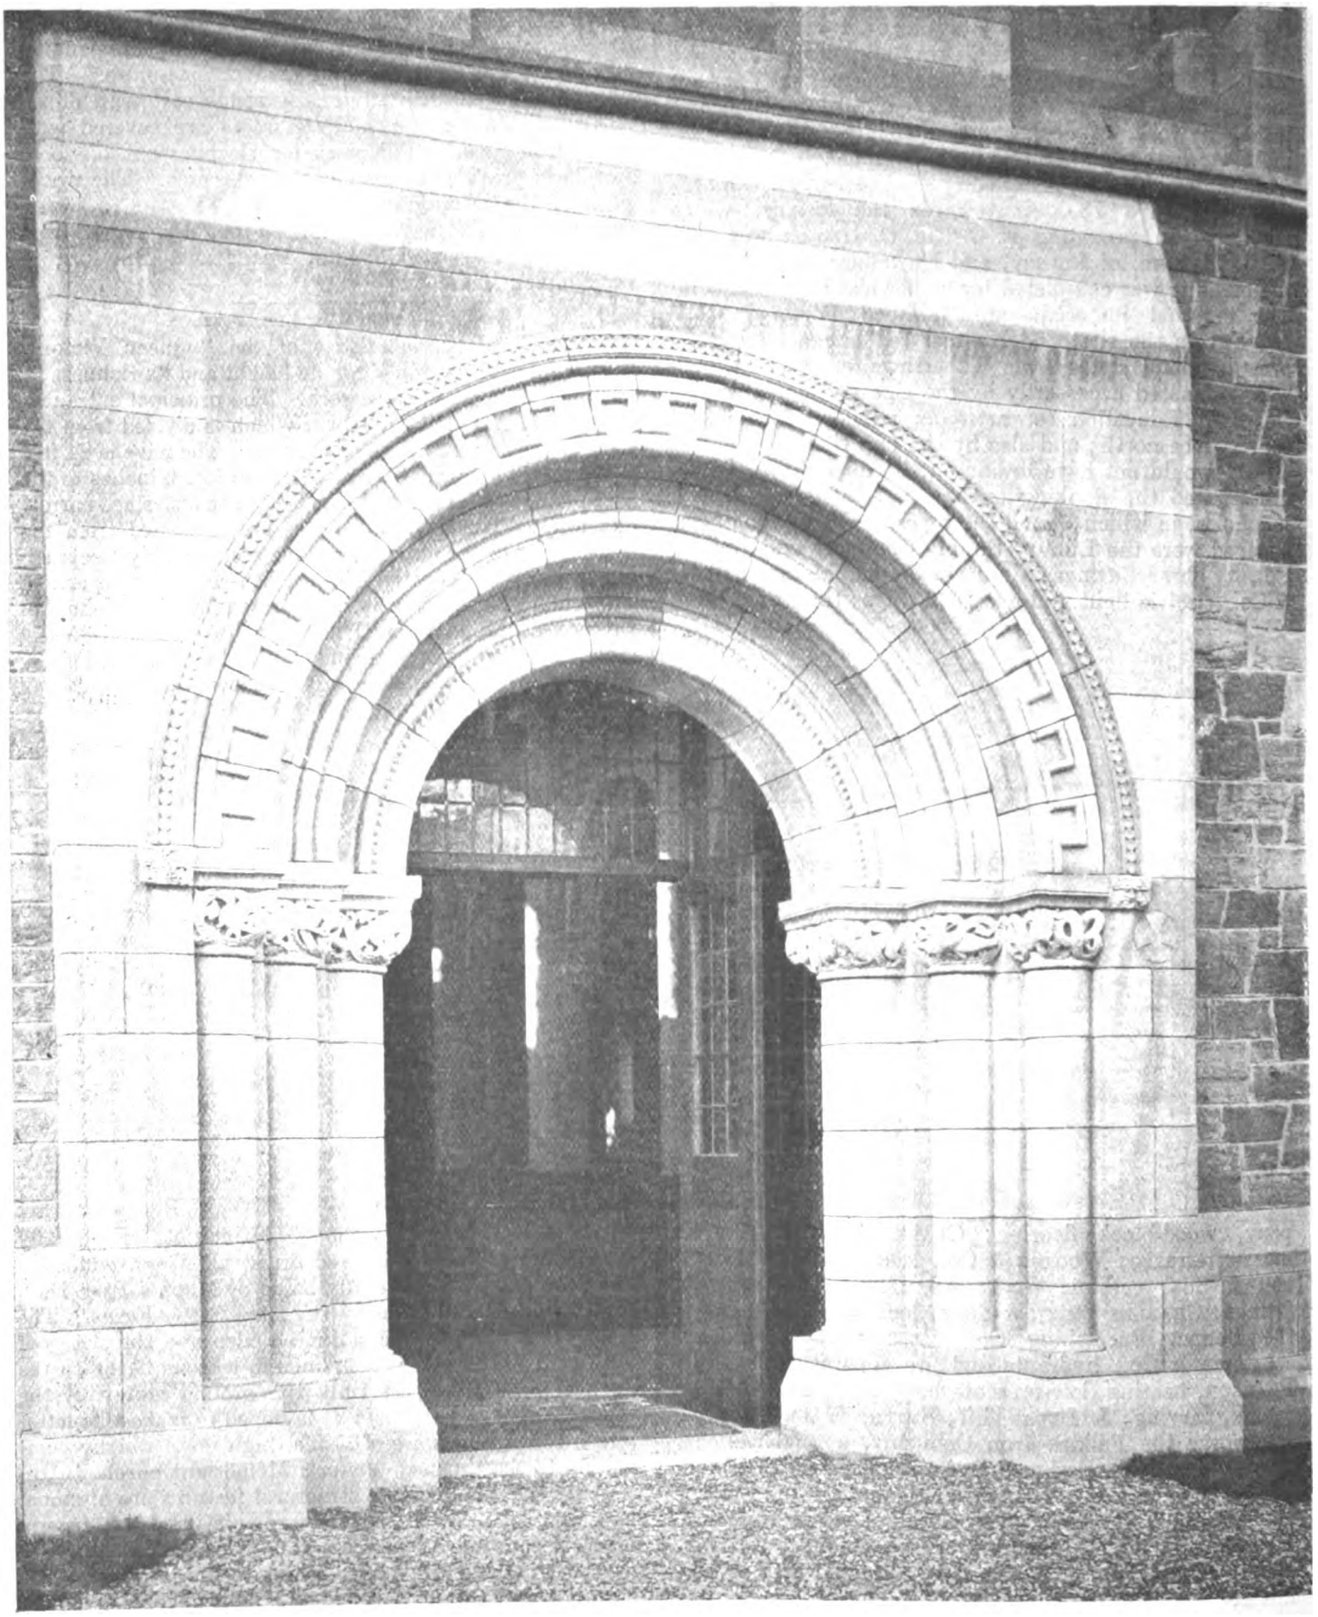
WALLS are faced with thin black country bricks and the roofs covered with hand-made tiles. External woodwork painted white with green doors. The work was carried out by Messrs. J. BARNSLEY & SONS, from the designs of Messrs. COSSINS, PEACOCK & BEWLAY, Birmingham.

HOUSE AT FOUR OAKS, NEAR BIRMINGHAM.

THIS house was built for Dr. LLOYD OWEN, M.D., F.R.C.S. The exterior is faced with silver-grey rough-cast, and the roof covered with hand-made tiles. The builders were Messrs. STREATHER & HILL, of Four Oaks, the architects being Messrs. COSSINS, PEACOCK & BEWLAY, of Birmingham.

CROPWOOD, BLACKWELL, WORCESTERSHIRE.

THIS house, the country residence of Mr. BARROW CADBURY, is built in an elevated position, commanding very fine views of the county of Worcestershire. The exterior is faced with silver-grey rough-cast with dressings of Guiting stone, and the roofs are covered with hand-made tiles. Balconies for sleeping out of doors have been provided to some of the bedrooms. The woodwork of the interior is chiefly oak. Messrs. J. & A. BRAZIER, of Bromsgrove, carried out the work from designs by Messrs. COSSINS, PEACOCK & BEWLAY, of Birmingham.



ST. AUGUSTINE'S CHURCH, FULHAM.

THE general characteristics of the "Queen Victoria Memorial Church" are its height and its richness in moulded and carved stonework. The principal entrances are at each end of the narthex, which is divided from the body of the church by a stone screen. The nave is 84 feet by 23 feet 6 inches. The height is 36 feet 6 inches to the roof-plate, and 52 feet to the ridge. The aisles are narrow and lofty. The nave and aisles are separated from the eastern end of the church by stone arches richly traceried, which give very effective views when seen in perspective. The chancel (which was consecrated by the Bishop of LONDON on Monday) is 21 feet 3 inches wide and 35 feet long. The five-light east window, filled with stained-glass, is at the level of the clerestory windows, and imparts an appearance of height to the whole interior. Externally the church is faced with red brick, all doors, windows, and moulded work generally being of Monk's Park Bath stone, worked and fixed by the Bath Stone Firms. The steep roofs are covered with red tiles and the flat roof with lead. The bell is contained in a stone flèche on the chancel arch gable, as only the ground storey of the tower is built at present. It is hoped to make this latter into a tower and spire, 160 feet high, as a worthy completion of the "Queen Victoria Memorial Church." Internally the whole of the structural features are of stone, and the plain wall spaces are plastered to receive future decoration. The roofs are of wrought timber, with arched trusses and hammer-beams to the principals, and with boarded ceilings throughout. The chancel is lighted by electricity and the nave with gas. The church is heated with two of GRUNDY's hot-air underground stoves. Accommodation is provided for 650 worshippers. The carving throughout has been done by Mr. N. HITCH, and all the handsome oakwork has been made by Mr. ROBINSON. The architects, Messrs. J. E. K. & J. P. CUTTS, supplied drawings in detail for the whole of the works and fittings.

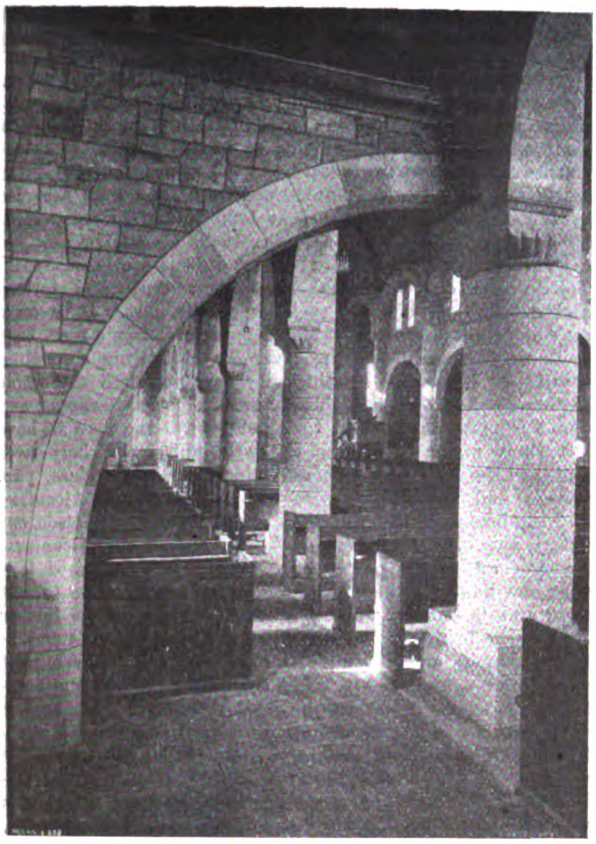
ST. LUKE'S CHURCH, EDINBURGH.

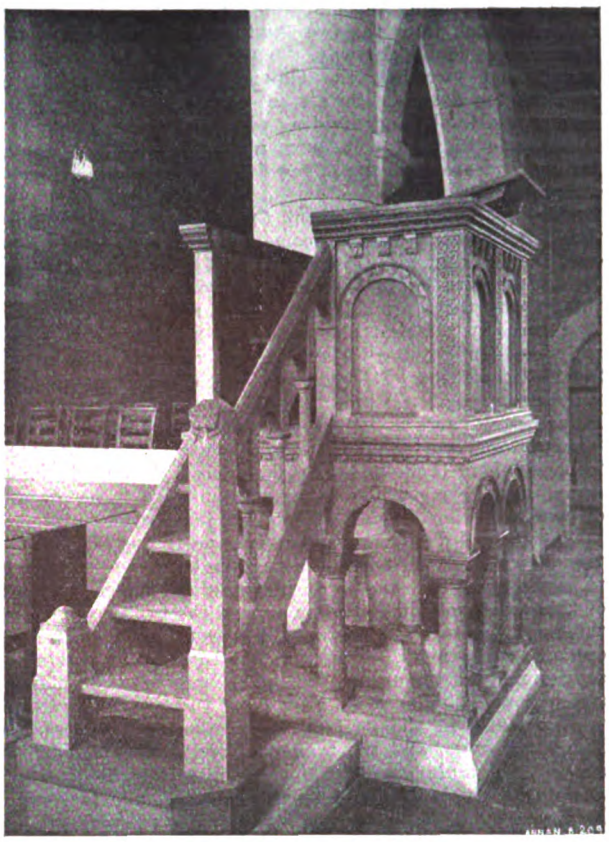
WE give detailed views of this church, which has been erected on an excellent site in East Fettes Avenue, Edinburgh West, from the designs of Mr. P. MACGREGOR CHALMERS, architect, Glasgow. Last week we illustrated the exterior and interior. The church is finished in stone internally and externally. The principal stone is taken from Dullatur Quarry, and the rubble from Hailles Quarry. The design of the nave arcades has been modelled on the Norman work at Jedburgh Abbey. Special attention has been taken in the carving of all the capitals; no two of them are identical.

ST. LUKE'S CHURCH, EDINBURGH.—THE MAIN ENTRANCE.



GOTHIC ART IN SPAIN.*

IN few countries has the influence of history on art been so marked as in Spain during the Middle Ages. The Moorish invasion of the greater part of the Peninsula early in the eighth century drove the Gothic races into the romantic fastnesses of the north, and there for three centuries, weakened by internal warfare, the Moors remained.



In the eleventh century the Christians, having regained their energy, reconquered Toledo and united the two Castilles. Henceforward and by degrees the Moors were driven southward, and finally, in the fifteenth century, the whole

THE PULPIT.

Peninsula was again under Christian rule. During these times the two great streams of Gothic and Saracenic art ran side by side, scarcely influencing each other, but steadily marking the advance or retrogression of each nation.

The mediæval Spaniards, born among such surroundings, and fired with that enthusiasm, the torch of which was kept burning by defending their faith and homes against a Mohammedan race, developed those national feelings for romance and drama which influenced their lives and work, so that romance and drama constitute the characteristics of their Gothic art.

The first serious attempts of Gothic art in Spain date from the end of the eleventh and beginning of the twelfth centuries, and the work is suggestive of the influence of the rich Romanesque art of the south of France, which art is a little earlier in date. It is also significant that the episcopate of the newly reconquered city of Toledo was held by a Frenchman, Bernard by name, through whose influence many French clergy were preferred to important positions in the Church in Spain.

The cathedral of Santiago in Galicia, that of Zamora, and the old cathedral of Salamanca, are the three leading churches of the first period of Gothic art in Spain. Santiago, commenced about the year 1078, is the earliest and largest. It is a noble example of a Romanesque church, cruciform in plan, with an apse surrounded by chapels and richly-carved western doorways. The fact of its completeness and general unity of style would make it most remarkable, for there is nothing in Spain of an earlier date which could lead up to such completion; but its great similarity to St. Sernin at Toulouse, which is earlier in date, makes it more than probable that the work was entirely carried out under French guidance, and although a more noble work than the other two, it is perhaps less interesting to the student of Spanish art. Zamora and Salamanca are smaller and later in date, but they have that individuality of their own which suggests that they were the cradle of Gothic art in Spain. These interesting structures were commenced early in the twelfth century; they are cruciform in plan, the crossing being covered by a dome or cupola surrounded by small windows. Internally the massive stone piers support simple unmoulded arches and the window spaces are but small apertures in the walls. A simplicity and unity of effect is obtained by the mass of light which pours in through the windows surrounding the cupolas and centres on the piers which support the crossing. This massing of light was the first suggestion of the drama of effect which stands out so conspicuously in the Gothic art of Spain.

The little old cathedral at Salamanca is now enveloped in the folds of the vast Gothic edifice which has superseded it, and it is difficult to gauge its earlier appearance. Zamora, on the other hand, is as it was 800 years ago. Rising on a rock on the northern bank of the river Douro, the time-honoured fortress and "well-walled town" retains much of its ancient warlike appearance. It is, however, no longer surrounded by all of its seven lines of walls; still it has that appearance of impregnability for which it was noted in mediæval times. Seen above the old brown walls, on the highest part of the rock, is the cathedral, strangely picturesque in outline. At the west end is a Romanesque tower of unusual proportions, and a dome at the crossing, transitional in style, but Eastern in appearance; these crown a short, massive church, which is more like some castle keep than a Gothic cathedral. This building, and that of Salamanca, were in progress during the episcopate of that warlike prelate, Geronimo, the confessor to the Cid, and well express the race and times.

The city of Avila, near Madrid, is even a more complete mediæval city than Zamora. It is surrounded by walls commenced in the year 1090, and is now the most perfect example of a walled city in existence. Mapped out on the slope of a hill, and looking much like an engraving in the *Nuremberg Chronicle*, it has stood still since the walls were the protection of its inhabitants, and is unaltered except by decay. Within these walls are three interesting examples of early Gothic art—the cathedral, St. Vincente, and St. Pedro. The date of their architecture is a little later than Salamanca and Zamora, yet in part they are coeval. The cathedral is a lofty cruciform church of the twelfth and early thirteenth centuries. The beautiful granite nave flooded with light from the lofty clerestory windows and noble choir built in a red veined stone, suggest but faintly the massiveness without. The transitional apse, forming a vast bastion in the walls and externally throughout the church, presents a fortress in itself, well suggesting the militant Christianity of mediæval Spain. St. Vincente and

Digitized by Google

St. Pedro are both twelfth-century buildings, the west front of the former being the glory of Avila. Set back beneath an arch which joins the two short western towers is a late Romanesque double doorway, the archivolt of which is richly carved and moulded, the classical acanthus leaf being amongst the details. Saints supported on columns stand against the jambs and dividing pier, and these, although a little crude in treatment, have a great amount of human feeling, and are earnestly engaged in conversation with each other.

The Spanish peasants think that the saints which grace the niches of their churches come down from their positions once in every hundred years, and, if they overstay their time, they turn again to stone, and so cannot return, and this is why there are so many empty niches.

Internally the church is solid and massive, with arches supported on circular columns, and vaulted with boldly-moulded cross ribs. St. Pedro, although less imposing, is as interesting as St. Vincente. The beautiful crossing is Romanesque, and is lit by a fourteenth-century lantern, which it supports. The roughly-chiselled carving and masonry, here brought into prominence by the light, melt away into the mysterious gloom of the nave transepts and chancel.

Tudela and Tarragona are exceptionally fine examples of transitional architecture. Tarragona by some is thought to be the finest building in the Peninsula. The general date of this great work is the latter part of the twelfth and early thirteenth centuries. The apse, however, which is Romanesque, is early twelfth-century work. Internally, the simple, solid dignity of the unmoulded arches, supported on massive stone piers, is relieved by grotesques and scrolls carved on the caps and in the string-courses; the grand balance of light and shade, and the beauty of proportion, are expressive of the manly power of this early style of architecture, a style in which Spain is especially rich. The interesting lantern at the crossing, formed into an octagon by pendentives in the spandrils of the arches and vaulted with bold groining ribs, is, I think, the first example of such a treatment in architecture. The cloister court is one of those silent gardens of loveliness in which architecture, mellowed down by time, combines with nature to form a dream of colour. The early-pointed arches of the cloister, divided by round-headed windows and circles enriched with the dog-tooth moulding, peep out between the luxuriant foliage which rises from a garden divided into paths by clipped and flowering shrubs, while here and there a fountain cools the fragrant air with its sparkling jet of water.

The cathedrals of Toledo, Burgos and Leon were built in that great period of mediæval art, the thirteenth century. Toledo, grandest of the three, is the finest example of Gothic in the Peninsula, and its solid magnificence, vast scale and the richness of its fittings place it amongst the finest buildings in the world.

The King Don Ferdinand III. and Archbishop Rodrigo laid the first stones of this church on August 14, 1227, and the architect, according to a contemporary inscription, was Petrus Petri. It is unfortunate that this inscription is in Latin, for it makes it impossible to decide with any certainty whether he was a Spaniard. Those who claim everything in Spain to be done by others than Spaniards, state that he was a Frenchman, Pierre le Pierre, while the Spaniards claim him under the name of Pedro Perez. Whether, however, Petrus Petri was a Spaniard or Frenchman, there is no doubt that on entering this grand building one is struck with an effect essentially different from that created by churches in other countries. The sombre impressiveness, the proportions, the drama of chiaroscuro stamp it with a distinct individuality, and even should the root have been transplanted from the soil of France, the tree has assimilated the poetry and drama of its Castillian surroundings. Its proportions are colossal, it being the third largest church built in Gothic times. Seen from the transepts it conveys the finest impression; the brilliant Spanish sunlight pierces the richly-coloured windows, striking in diagonal shafts across the dark, mysterious voids, here and there lighting up a column or exquisite bit of carving, and glistening on the silver chastening and copper-gilt details of the screen. The air is filled with the aromatic scent of incense, and the pale, grey smoke which rises from the censers lingers about the cavernous arches, and mingles with the mysterious atmosphere which envelops the vaulting. Nowhere else is architecture so dramatic, so full of mystery. The cathedral is cruciform in plan, with an apse at the east end, and has double aisles which are continued round the chevet. The capilla major is enriched with carvings and tombs of the fourteenth, fifteenth and sixteenth centuries, and cut off from the transepts by the most interesting and magnificent metal screen in the country of metal screens—Spain.

The high altar is in late Gothic design, elaborately carved in wood, gilded and painted, and, altogether, this capilla major is the most gorgeous work of Gothic art in existence, and well represents the epithet of wealth applied to Toledo Cathedral (Toledo for wealth, as the Spaniards say). The stalls are in delicate Renaissance work, and were designed by Maestro Rodrigo in the year 1495, and the metal screens by Domingo Cespedes in the year 1548.

This jewel of Gothic art is set in the crown of Spain. Toledo, the once imperial and magnificent, now forlorn and desolate, is but the skeleton of the past. Built on a rock of granite, the venerable frame stands like a rock, on a rock girdled round by the river Tagus boiling through a ravine at its feet. In this city is epitomised the whole history of the Peninsula. Romans, Visigoths, Saracens, and again Christians, have in turn held sway, and here all have left their mark. Crossing the wild and melancholy river and linking up its rock-bound sides are two bridges, part Gothic and part Saracenic—the bridge of the Alcantara and the bridge of St. Martin. When arriving at Toledo, one enters the city by crossing the bridge of the Alcantara. Passing under the portcullis of the gate, one indeed feels that one has left the dull commercial world of the present day, and is entering the age of chivalry. On the further side of the bridge still stands the Moorish tower restored in Gothic times, and the narrow road supported on one great arch which spans the river was rebuilt in the thirteenth century. A small panel in the wall records the fact that it was rebuilt after a great deluge of rain commencing before the month of August and lasting until December 26 in the year 1258. The bridge of St. Martin is even more interesting than that of the Alcantara. The great spanning arches were rebuilt probably after the same flood. The gateway, however, is a work of Moorish art of the ninth century. Above the bridge rises a grand view of the rock-built city. Conspicuous is the church of St. Juan Los Reis, the walls of which are covered with votive manacles given by descendants of families who were freed from Moorish bondage when Toledo was reconquered.

The great works in Toledo are numberless, but we cannot leave this city without mentioning the one small vein of art into which the streams of Christian and Saracenic architecture intermingled, and gave the very rare style of Moresque. In a town which had been reconquered by Christians after the Moorish occupation, many Moors of the artisan classes remained, and being a skilful people they were employed on the buildings erected by their Christian masters. On rare occasions these buildings were entrusted to their hands, and in these one finds a style founded on Gothic construction, but in detail Moorish; such is the thirteenth-century brick tower of St. Ronan, the apse of St. Christo de Luz, and several other churches. In the choir triforiums in the cathedral there is a slight suggested trace of Moorish influence in the upper arrangement of the interspanning arches, but here it is the motif which is Moorish, the detail being purely Gothic.

The foundation-stone of Burgos Cathedral was laid in the year 1221, during the episcopate of Bishop Maurice, an Englishman, and the original fabric of this great church was completed in the incredibly short time of nine years. The church is cruciform in plan with single aisles and an apse, and is surrounded by lateral chapels. Externally the rich outline of the spires, octagon, and great octagonal chapel at the east end, are features superimposed on the original structure, and, owing to the situation, these additions are always conspicuous, and give the appearance of a church of much later date. The interior is a magnificent example of architecture. At the moment of entering from the western doorways the effect is somewhat injured by the blocking up by the coro, but from the choir or transepts, the fine effect of proportion, the drama of chiaroscuro, the beauty of the carving and the richness of the fittings are unsurpassed. No doubt much of this effect is given by the light flooding in from the late octagon, which octagon is condemned by authorities who can see beauty only in purity of style and academic art; still, those of broader mind can at least here put on one side their more fastidious tastes to enjoy what is probably the most perfect drama in architectural art.

The old Gothic lantern having fallen down in the year 1539, the present one was commenced by Juan de Borgona, and completed by Juan de Vallego in 1567. It is Gothic in form, but Plateresque in detail. From an architectural

Digitized by Google

point of view it does not bear analysis, but as a combination of motif and detail it triumphs over rule and produces one of those impressions which time can never obliterate.

The spires and octagonal chapel were designed by John of Cologne, and carried out between the years 1435 and 1456; and, although German in style, the detail is much influenced by Spanish art. The interior of the octagonal chapel is vaulted in most delicate interlacing work of late Gothic design. The stone is smooth and cream coloured, and the carving throughout is so exquisitely minute that the general suggestion is that of an ivory casket. In front of the Renaissance altar is the tomb of Don Ferninando de Velasco, the Constable of Castille, for whom this chapel was built, and it is still the property of the same family.

The cathedral at Leon, commenced in the year 1214, is much more correct according to the laws of northern Gothic architecture. Lightness and grace are its chief features; the aim seems to have been to use the least possible amount of material with the greatest amount of space and effect. In France, at the same period, a similar attempt was being made in the church at Beauvais, and in both a like result followed, that of the constant difficulty of keeping the church in structural stability. It is quite northern in plan, and although not nearly so long, otherwise the proportions are the same as those of Westminster Abbey. The bays are lofty and slender, the triforium pierced, and the clerestory, which is nearly half the height of the building, completely filled in with a six-light window. Shortly after its erection, however, for the sake of increasing its stability, two of the lights were filled in. Externally the church is not satisfying when compared with such exquisite examples of this style of architecture as those existing in the north of France. One cannot but help feeling that here the Spaniard was treading on ground which he did not fully understand, and that there is little really Spanish in this undoubtedly fine cathedral.

Elsewhere in Spain one comes across this extremely lightly-built Gothic, but the style never left its French origin, and was never quite satisfactory on Spanish soil. Perhaps the best works in this style of art in Spain are the western doorways of the cathedral at Vitoria. These are perfect examples of northern French art, and suggest not only that the architecture was French, but that even the carvers and masons must also have been. This cathedral and one or two of the churches in Vitoria are so lightly constructed in stone that great uprights have been placed in front of the columns to give extra stability to the vaulting, a necessity which is quite ruinous to their architectural effect.

In the fourteenth century Gothic art in Spain developed more purely on national lines, and French influence seems to have quite disappeared. The most interesting buildings of this period are to be found in Catalonia and Aragon. A school of architects had sprung up in the Island of Majorca of which the leading light was Don Jaime Fabre. Much interest had been aroused by the Dominican church he was erecting at Palma at the end of the thirteenth century, now unfortunately destroyed except the cloisters, which are used as a prison.

In the year 1298 the King summoned Fabre to Barcelona and requested him to make plans for the new cathedral. These designs were put in hand at the commencement of the fourteenth century, and a very interesting agreement between Fabre and the clergy is still in existence. According to this agreement Fabre was both architect and builder. It enters minutely into all arrangements about payments and duties of the architect, and I think I am right in saying that it even states that during Fabre's residence in Barcelona he was to have two new hats a year. This cathedral is oblong in plan, with an apse at the east end, the crossing formed by the transepts being flush with the outer walls of the aisle chapels. At the west end is an octagon only partly carried up in mediæval times, but now being completed. The nave is very lofty, and the groining of the roof starts from the caps of the nave piers, leaving but small space above. The triforium and clerestory are represented by a narrow arcade and circular windows. The window spaces are all small except those round the apse, and they are filled with fine old glass. The chevet is seven-sided, the tall slender columns supporting stilted arches, and the stone is a rich russet colour. When one enters the transept door from the brilliant sunlit streets the darkness is profound; but by degrees, as the sight gets accustomed to the gloom, here and there parts of the glorious architecture stand out where they intercept shafts of light, and the tall graceful arches of the chevet rise in dark relief against the jewelled background of the richly-coloured glass in the apse. Boldly bracketed out above an arch in the north transept, the great organ rears its mass of finely-carved plum-coloured wood, and the delicately canopied stalls in the trascoro form a filmy group of cobweb spires, from the sides of which spring up the piers of clustered shafts supporting the arches and groining of the roof. All above, though, is lost in mystery, a dark impenetrable mystery, through which floats the pale blue smoke of incense.

The great French cathedrals may be finer architecturally, may be more perfect in proportion and detail than this church, but is not the atmosphere which pervades a building more eloquent than the stone itself, and can architecture rise beyond that which impresses the mind with the mystery which surrounds our life and leads us to the contemplation of a future state?

The cathedral of Palma, rising in a golden mass of masonry from the shores of the Mediterranean; the square-planned cathedral of La Seo, at Saragoza, and many others in this district, are all remarkable for that strange impressive atmosphere, and, like great works in Nature, grasp the mind and lead the thoughts to contemplate the mysteries of the future.

The cathedral at Gerona is another exceptionally interesting fourteenth and early fifteenth century building. The choir apse and choir aisles are planned on the usual French arrangement, and were carried out in the early fourteenth century. In the year 1416 Guillermo Boffy, who was then master of the works, made a design for completing the church by the addition of a nave of a single vault of 75 feet, the arch completely spanning the choir and its two aisles. As might be imagined, this suggestion seemed so hazardous that the chapter of the cathedral called together a meeting of the most illustrious architects of Spain to discuss the possibilities of such an erection. After due deliberation the designs were approved, and this, the widest Gothic vault in the world, was erected; it is at the present day in perfect structural condition. (For comparison with our English churches, Westminster Abbey is 38 feet, and York, our widest span, 52 feet, whereas Gerona is 75 feet.) When one enters, the great cavernous space appears larger in proportion than it really is. That mysterious gloom which is usually present in Spanish churches is here pierced by a great diagonal ray which, striking from the south windows, floods the three chancel arches with light. Far off in the distant gloom are seen the graceful, stilted arches of the chevet, and here and there a jewel of colour sparkles in the windows of the apse. The artistic effect is perfect, the drama sublime. This arrangement of light and shade is undoubtedly as much part of the design as the columns and arches, the groining of the roof or plan. This mass of light passes through three richly-stained glass windows in the south-east corner of the nave; all other window spaces are but panels in the walls. Critics say this grand effect is but the outcome of chance, that the architecture, being borrowed from a northern source, had too much window space, hence much had to be blocked up, and time, the mellower of all things, has mellowed down a crude and barbarous makeshift. Has time or accident written avarice in the eye of the moneylenders by Quentin Matsys, or woven the golden light which illuminates a head by Rembrandt? No, this is art, consummate art, art which is akin to that of poetry and music.

Many of the documents connected with these great buildings are remarkable, for they prove how great was the care and thought bestowed on every minor detail. Perhaps one of the most interesting is that connected with the completion of the Miguelete at Valencia. This proves that even in the days when Gothic was a living art it could not be produced without great effort, and, just as to-day, resort had to be made to selection. This manuscript states that Peter Balaguer, an able architect, shall receive fifty florins from the fabric fund of the new campanile in payment of his expenses on the journey which he made to Narbonne, Lerida, and other cities, in order to see and examine their towers and campanili, so as to imitate from them the most elegant form for the completion of the tower at Valencia. This tower was commenced in the year 1381, Juan Frank being the architect, and evidently, the tower not being considered satisfactory, they sent this other architect to get some better suggestions for its completion than that of the original designer.

The romantic beauty of this rock-bound land gave opportunities quickly grasped by mediæval builders, and Manresa, in its poetic situation, is one of those dreams in which they loved to dwell. Perched on the summit of a rock which is broken into picturesque hollows filled with gardens, the

Digitized by Google

church crowns the lofty eminence; crossed by ancient bridges at its base, the rushing river Leobregat winds between huge rocks and olive yards; and faintly seen on the horizon are the pale blue mountains, far off spurs of the noble range of the Pyrenees. The great ship-shaped rock, Segovia, is at times an unequalled vision of romance. Built up amongst the mountain heights, the mists descend, and as they slowly wind around its base, it seems as though the rock-built ship is moving, supporting on its decks the wall-girt town, the prow crowned with the towers and turrets of its castle. The situation is indeed unsurpassed for beauty and strength. In the castle, which in mediæval times was impregnable, was kept the money reserve of the kingdom, the mint being in a small building on the river at the base of the rock.

The fifteenth century gave to Spain its largest and, perhaps, most famous Gothic work and the largest Gothic church in the world—Seville Cathedral. It was commenced in the year 1403, and completed about a century later. The great building covers an oblong, 414 feet long by 271 feet wide. It has double aisles and lateral chapels. The coro, as is usual in Spain, fills up the centre of the nave. This arrangement of the coro is necessitated by the elaborate ceremonies and the number of clergy who take part in them. The centre of the church being enclosed led to the buildings being planned shorter and broader so as to allow more space for the people crowding round the sides of the high altar to attend the sermons at High Mass. In the larger cathedrals, such as Toledo, Burgos, Seville, &c., there are sometimes two or three high masses, with organ and full choir proceeding at the same time. The public, as a rule, attend masses in the side chapels, and the service at the high altar, except the sermon, appears to be principally for the clergy.

This arrangement, by which the choir is continued into the eastern bays of the nave and enclosed by stone screens (the trascoro) has been very adversely criticised by authorities on architecture, and from the point of view of the general vista, on entering by the western doorways it certainly is in many cases most injurious. The screens, themselves, however, and the fittings which they enclose are occasionally of such great beauty that they sometimes even more than compensate for the injury done. This arrangement was probably introduced in the fourteenth century, the period at which the churches became much squarer in plan. In such a case as La Seo, at Saragoza, which has a nave and four aisles all of the same height, and with the length and breadth equal, the enclosed coro adds immensely to the effect.

The interior of Seville is noble in the extreme. The massive nave piers rise in moulded shafts, broken only by narrow caps running round the arches and groining of the roof. The immense height of the arcade is carried through the space which in most cases in our English churches would be the triforium. This gives the proportion which so great a scale requires. Beyond the crossing the high altar towers above the coro in a dark mass of carved and gilded wood, and between the nave piers is seen the forest of massive columns which support the double aisles and surrounding chapels.

The sombre majesty of the effect, the richness of the glass and fittings, the dignity of the architecture, well portray the Spanish epithet of solemnity applied to this cathedral, and produce an effect akin to that experienced when contemplating the greater works of Nature. In 1889, part of the vaulting above the choir fell down, and fear was felt for the general stability of the building. This damage has been repaired, and so excellent is the restoration that the appearance of the building is quite uninjured.

In the sixteenth century, when most countries had adopted the Renaissance art, Spain still held on to Gothic form for its ecclesiastical architecture, and the two great buildings of Salamanca and Segovia are the last great Gothic works erected. In the year 1513 the clergy called together a number of architects to draw up a report setting forth the essentials of such a building as they wished to have. This report decides not only the size and proportion of the building, but even such projections as buttresses, &c. Amongst these architects Juan Gil de Hontanon was selected by the chapter to carry out the building. In 1522, the same architect was called in to design the cathedral at Segovia; at his death this work was completed by his son, Rodrigo Gil de Hontanon, in the end of the sixteenth century. These two great buildings, the last spark of the fire of Gothic art, group up in massive towers and domes, crowning the towns over which they rise with majesty and domination. In detail, perhaps, they do not bear analysis, they may have faults of ostentation, but as expressions of the thoughts and minds of those who reconquered Spain to Christian rule and advanced their banner to a new-found world, they are works of expressive art and grand dramatic power, and form a fitting climax to the growth of that art of which they are the final utterance.

ART IN EDUCATION.

"ART as a Subject of General Education" was the subject of a lecture which was delivered in the theatre of the Royal Dublin Society recently by Mr. James Ward, Hon. A.R.C.A., London, under the auspices of the Arts and Crafts Society.

In all their schools, the lecturer pointed out, nearly every subject of general education was compulsory or was thought necessary for the proper education of the average boy or girl, except the subject of drawing or art knowledge. When it was taught it was taught in a tentative way. In some schools it was still treated as an "extra subject." Drawing, he urged, should be taught to every boy and girl in their schools by properly qualified experts, and as much time should be devoted to this subject as to any of the other lessons, for it might easily be shown a knowledge of drawing, or art, was quite as important in the education of boys and girls as any other subject of school study. If drawing had its proper place in their schools it would lessen the overwhelming number of candidates for clerkships, Civil Service and otherwise, and shop salesmen, the supply of which greatly exceeded the demand. It would be better if more attention were paid to the directing of pupils to the dignity of labour as expressed in the work of the mechanic, the artisan, and the craftsman. The elements or principles of technical knowledge should be taught in every school, and, as drawing was the foundation of all technical knowledge, it should have more hours in the week devoted to it in the schools than it had at present. They wanted to have a love for and an appreciation of good art; for, in spite of the writings and teachings of Ruskin, Morris, and others, and of the establishment of museums, picture galleries, and schools of art, a knowledge of art, or an adequate art culture among the masses of the people of these countries was at present very small indeed, and would likely remain so until the subject was accorded its just and equal measure of importance with the other subjects in the curricula in their schools and colleges. The lecturer proceeded to deal, says the *Irish Times*, with the close relationship which existed between Art and Nature. Emerson had said "Art is Nature passed through the alembic of men." The highest form of art, like nature, was creative and original. A full and liberal education, which must include art culture, would fit those who might be called upon to take up certain positions in life, where they might act as directors or guides to the community at large. They would not be surprised to find that art education was at present treated with so much indifference when it was considered that they had not yet seriously thought of it as an important factor in the welfare of the nation, not to speak of its commercial value to the State. A considerable portion of the wealth of France was derived from the profits on the goods and wares of an artistic nature, which were turned out annually by the deft fingers and fertile brains of French men and women. Was it not the imperious Parisian milliner who dressed the feminine world? Germany and Switzerland were rapidly adopting the French ideas and methods of art instruction in their schools and colleges, and were establishing and developing new institutions known as trade art schools, where boys and girls were taught for a term of four years in the subjects of drawing, modelling and design, as applied to all trades and manufactures where an expert knowledge of art was essential. England was just beginning or thinking about the establishment of such schools, but, as far as he was aware, the movement had not yet reached Ireland. There were many modern instances where both clergy and laity had unknowingly, he admitted, acquiesced in the disfigurement of their churches and cathedrals by allowing inartistic people to cover the walls and vaults of their sacred edifices with commonplace designs and crude colouring, entirely out of harmony with the architecture and uses of the fabric. In churches so disfigured, and there were many of them in Great Britain and Ireland, the worshippers who might have the fortune or the misfortune to possess an artistic taste, found it very disquieting to their peace of mind to sit throughout the length of a service in a badly-coloured church, because however devoutedly they might be disposed, it would certainly "mar their calm," if not irritate their sense of proportion and fitness of things. Better far to keep to the puritan,

Digitized by Google

whitewash in our churches than to make them the examples of commonplace and misapplied decoration. Much of the modern stained glass was imported from foreign countries, and its greatest recommendation was its cheapness. It was clear that their bishops, deans, chapters and churchwardens would be all the better for a little education in art matters, especially if their churches were in need of stained glass. It was the duty of all committees who had to superintend the erection and decoration of public buildings and churches, to employ expert advice if none of their number were possessed of artistic knowledge. Nature-study ought to prove a delightful and charming recreation or change from other school lessons of the children, if the subject was taught in an intelligent way. Referring to the new Universities, he said he sincerely hoped that provision would be made for the foundation of a professorship, or a lectureship, in art, so that the future graduate should be enabled to pass through the new Universities, carrying with him an appreciation, at least, of the aims and significances of art. The governing body and senate of the National University would surely see that some form of art culture must needs be a part of the college curriculum, because they could not allow Ireland to be behindhand in this matter. There was no better way of learning history than by studying the art and architecture of a country, and certainly none more interesting. In fact. the history of every ancient and mediæval nation was largely written in the remains of art and architecture. With the knowledge of art their lives would be happier and brighter. They should not look on art as a luxury. They should look on it as a valuable asset, which would have a refining influence on the lives and manners of the people.

THE ULSTER SOCIETY OF ARCHITECTS.

THE annual report of the above Society was presented at the last meeting. In the course of it the Council say that during the progress of the Irish University Bill through Parliament the following resolution was passed by the Council:—"That any university created for Belfast and the province of Ulster will be incomplete unless provision is made for the establishment of a Chair of Architecture therein, and it is essential that sufficient funds be provided by the Government to enable the statutory authority of the proposed university to provide such a chair." The Queen's University of Belfast has now become an accomplished fact, and it is hoped that the Senate will be able to fulfil the wishes of the Society. The Council has not allowed any opportunity to slip of using its influence to stop the demoralising practice of public officials engaging in private practice. During the year the Urban Council of Bangor made an appointment of surveyor for the district, and it was made a condition of the appointment that he was not to engage in any private practice. Following the comparatively satisfactory arrangement made by the Holyrood Urban Council reported last year, this is considered very encouraging. The Commissioners of National Education and the Local Government Board have recently become active agents in supplying stock pattern plans for the erection of schools and labourers' cottages, which are in some cases being availed of by local committees and authorities regardless of their unsuitability to local circumstances, site and material, which can only be properly met by the employment of a qualified architect in each individual case. Like most model plans, they are usually unsatisfactory, except where they are plagiarising—a circumstance not unknown—from the designs of architects lodged with the Department. This matter has received attention, and further action will be necessary to protect architects' interests as well as prevent waste of public money. The unnecessary difficulties that were experienced by architects in obtaining the approval of plans by the city surveyor for trifling alterations induced a member of the Council, in a case in which the disapproval of a plan seemed uncalled for, to seek to have the law settled by a superior Court. This action resulted in obtaining a clear definition of the surveyor's duties, which, in the case of alterations that do not involve the taking down one-half of the area of the front wall towards the street, are to be limited to seeing that the by-laws in force are not contravened. The Council has recently addressed a communication to the Senate of the new Queen's University of Belfast with reference to the appointment of an architect for the buildings required in connection with the university scheme. This is one of the most important architectural problems which have arisen in Belfast, and it would be deplorable if it were not dealt with in the best possible way, both for administrative facility and architectural effect. It has been suggested that this can only be obtained by a competition, the conditions of which should be drawn up by an architect of the highest standing, and that as the university is intended to afford educational facilities primarily for the Province of Ulster, the competition should be confined to qualified architects (many of whom are former students of the Queen's College) practising in that province. By this means, says the report, the result of the consideration of the requirements by several minds would be obtained, and the appointment would be made on the merits, and not through the influence of friends, perhaps accompanied by the still more objectionable method of canvassing.

AMENDMENT OF THE LONDON BUILDING ACT.

AT a conference held at the County Hall on January 14, called by the superintending architect of the London County Council "to consider the questions raised in Part V. of the London County Council (General Powers) Bill," there were present representatives of the Councils of the Royal Institute of British Architects, the Surveyors' Institution, the Institution of Mechanical Engineers, the British Fire Prevention Committee, the Concrete Institute, the Institute of Builders, the London Master Builders' Association, and the District Surveyors' Association, when the following resolution was carried, with one dissentient:—

"That the scope of the said Bill (Part V.) should be limited to the construction of enclosing—i.e. external and party—walls."

The Council of the Institute had the matter before them at their meeting last Monday and passed the following resolution:—

"That the Council of the Royal Institute of British Architects unanimously endorses the resolution passed at the conference held at the County Hall on the 14th inst., and urges that the draft Bill should be amended accordingly. That a copy of the report of the conference and of this resolution be sent to the clerk of the London County Council and to the superintending architect."

Correspondence

[*The Editor will not be responsible for the opinions expressed by Correspondents.*]

Plumbers and Plumbing.

SIR,—Under this heading appears a letter in your issue of January 22, from a Mr. A. A. Adams.

Personally I tender my apologies for having forgotten the existence of the few London plumbers who have assumed the description of "The Associated Master Plumbers," a title which is sufficiently vague to disguise the parochial nature of its membership and the paucity of its numbers.

As President of the Institute of Plumbers of Great Britain and Ireland, an institution which is national in its scope and organisation, I claim the right to speak authoritatively on behalf of the great majority of plumbers in this country, both in London and the provinces, who have sufficient confidence in their ability to control matters which affect their own particular trade (like other trade and professional organisations), without delegating that authority to an alien body which has no connection with plumbing except in name. For these I do not wish to speak.—Yours faithfully,

WILLIAM CHALLONER,
President, Institute of Plumbers.

20 Tothill Street, Westminster.

Concrete Aggregates.

SIR,—I quite agree with the remarks of your correspondent "M. C. I." when he says "that whilst elaborate specifications and standards have been prepared for the cement and other binding materials, the question of the equally important aggregates has received little attention."

I have had occasion during the last few weeks to examine and report on the failure of two concrete jobs. In the first one five parts of gravel to one of cement were used. The cement was found to be perfect in every respect, but the gravel contained 7½ per cent. of loam. In the second case, seven parts of blast-furnace slag were used to one of cement.

Digitized by Google

The latter again was found perfect, but the slag contained 12 per cent. of sulphates!

Notwithstanding this, no amount of argument could convince the builders that the failures were not caused by the cement. Most architects will specify that a clean suitable aggregate is to be used, but although he may have his cement tested, he will rarely trouble to have the aggregate analysed.

Considering the immense improvements in the manufacture and quality of Portland cement during the last few years, and the extraordinary precautions which are taken by all high-grade manufacturers to prevent inferior cement getting on the market, it is of far greater importance for the users to ascertain the quality of the aggregate, as this is more likely to be the cause of failure than the cement.—Yours, &c.,

January 22, 1909. T.

GENERAL.

Mr. John Slater, F.R.I.B.A., has been appointed by the Council of the Royal Institute to succeed the late Mr. E. A. Gruning as a permanent member of the Tribunal of Appeal.

The Surveyors' Institution will hold their annual dinner at the Hôtel Métropole on February 23, and not on February 16 as at first announced.

The Town Clerk of Dundee has received official intimation from Edinburgh that the claim by Mr. Mackison's trustees against the Corporation for his services as sanitary inspector is not to be insisted on in the appeal. The sum asked for under this head was 3,800*l.*

The Coventry City Council on Tuesday decided to organise a competition for designs for municipal buildings along Earl Street.

A Fund is to be raised for carrying out a scheme for the restoration of St. Nicholas Church, Rochester. The parish dates back to the time of the Norman Conquest. The church was erected in the fourteenth century, and partly rebuilt in the seventeenth century; it adjoins the cathedral. It was resolved that the work be approved at the estimated cost of 10,000*l.*, and that a committee be appointed to collect the necessary funds.

Mr. Frith, sculptor, and Mr. F. Pearson (consulting architect of Truro Cathedral) have been commissioned to execute the design of a memorial to be erected in the cathedral by public subscription in commemoration of the public services rendered by three distinguished Cornishmen—Lord Godolphin, who was Lord High Treasurer under Queen Anne, Sir John Eliot, the parliamentary leader in the time of Charles I., and Sir William Molesworth, Bt., who was the first statesman to hold the office of Secretary of State for the Colonies.

Fifty-nine Competitive Designs have been sent in for the offices to be erected at Truro for the Cornwall County Council, and nine have been selected by the office committee to go before the assessor. The estimate ranges from 10,000*l.* to 50,000*l.*

Fifteen Hundred Examples have been selected from the recent exhibition at the last International Art Congress, South Kensington, by the Dublin technical education committee for display in that city. These works comprise examples of drawings from primary, secondary and technical schools and schools of art in England, Scotland, Holland and America, and are illustrative of complete courses of study, from the most elementary grades of work to their highest application to art, crafts and industries. The exhibition will open on Monday.

The Board of Management of the Edinburgh College of Art, after careful consideration of the record of all students who completed the five years' curriculum of the architectural section of the Edinburgh (Royal Institution) School of Art in July last, have awarded travelling scholarships of 40*l.* to Adam Bruce Thomson and John B. Lawson, tenable for four months during the present year, along with diplomas of merit. Diplomas have also been awarded to F. D. White, D. J. White, and G. F. Kay; and certificates to G. H. Watson, S. H. T. Smith, and H. Sykes Mitchell.

The Council of the Royal Glasgow Institute of Fine Arts are considering a scheme for the extension of their galleries in Sauchiehall Street.

Mr. Edwin T. Hall, V.P.R.I.B.A., the assessor in the Bristol Royal Infirmary competition, has made his award with the following result:—First premium, Mr. H. Percy Adams, of London; second premium, Messrs. Henman & Cooper, Birmingham; third premium, Messrs. Worthington & Son, Manchester.

At a Meeting of the Royal Academy on Wednesday evening Mr. W. Goscombe John, A.R.A., was elected a full Academician, Mr. Bertram Mackennal an Associate, and M. Jean Paul Laurens Honorary Foreign Academician.

The Wolverhampton and District Architects' Association held last week their annual meeting at the Law Library, Lych Gates. The following officers for the ensuing year were appointed at the last quarterly meeting:—Mr. William Edwards, president; Mr. W. J. Oliver, vice-president; Mr. A. W. Worral, hon. treasurer; Mr. William J. H. Weller, hon. secretary; Messrs. F. T. Beck, J. Lavender, and T. H. Fleeming, members of the Council; and Mr. Ashton Veall, hon. auditor.

The Berkshire County Council have instructed their county surveyor to furnish such information as may be needed for inviting competitive designs for new county buildings at Reading. The following are the items of the estimated cost:—Purchase of No. 26 The Forbury, and compensation to tenant, 2,110*l.*; cost of pulling down the existing buildings at Nos. 26, 28 and 30 The Forbury, and rebuilding, 10,000*l.*; architect's fees and premium on competition, 540*l.*; legal expenses, 100*l.*; various (including rent of and adapting proposed temporary offices), 1,000*l.*; total, 13,750*l.*

The American Institute of Architects has now 868 members, composed as follows:—320 Fellows, 548 Associates, as well as 63 honorary members and 83 corresponding members.

The Scottish Modern Arts Association have been presented with a characteristic landscape by Mr. Nathaniel Hone, of the Royal Hibernian Academy. Hitherto its acquisitions have been confined to members of the Scottish school, but the acceptance of this canvas is in accordance with the constitution of the Association, which permits of "the acquisition of works of art by artists other than Scottish." The landscape, entitled "A Derelict," is a forceful and impressive rendering of a storm along a rocky coast line.

Two Mural Paintings by Sir W. B. Richmond, R.A., in the central hall of the new Sessions House, Old Bailey, are now free of scaffolding. The subjects are "Roman Law" and "Spartan Law."

The Committee of the National Housing Reform Council are organising a tour next Easter which will probably include visits to Cologne, Düsseldorf, Essen and Frankfort, and other German cities possessing good examples of town-planning.

The Report of the departmental committee on the Inebriates Act makes the following reference to the excessive expenditure by local authorities:—"We are not prepared to justify the erection of reformatories at anything approaching the amount per bed expended by the Lancashire, Yorkshire and London County Councils, even though subsequent additions, put up at much less cost, may reduce the amount per bed considerably below that now stated. We consider the expenditure by those bodies upon new buildings (596*l.*, 542*l.* and 403*l.* respectively per bed) is unjustifiable and a waste of public money. Magnificence of design, arched ceilings, oak-panelled board-rooms with expensive wood carvings, elaborately tiled passages and stained-glass windows are not essentials. In making provision at the public expense, the normal requirements of the persons to be provided for should be the chief consideration. The conditions should be improved only to the extent which is essential for his proper treatment as an inebriate; and the fact that such conditions have been secured to the satisfaction of His Majesty's inspector, at so low a cost as 100*l.* per bed, makes it impossible to justify the far higher expenditure incurred by the local authorities."

At Plymouth County Court last week the case of Williams *v.* Luke was again mentioned. It was an action in which arose the question of the training of a young man named George Williams by Mr. Montague Luke, architect, Plymouth, with whom he was articled. His Honour called the plaintiff's father before him, and pointed out how difficult it was to prove that proper attention had not been given to his boy. It was not right to suppose that an articled pupil had the right to claim the same attention from a professional man as a scholar would require from a schoolmaster. After the parties had consulted with their legal representatives, Mr. Pearce announced that they had agreed that the case should be struck out of his Honour's list on terms, one of which was that the parties would withdraw all allegations. His Honour expressed his pleasure at the result.

The Architect.

THE WEEK.

Possibly the day is coming when the twentieth-century British architect will be as well aided in the carrying out of his designs by skilled craftsmen as were, apparently, the architects of the English Renaissance in the seventeenth and early eighteenth centuries. There can be little doubt that in those days the actual carvers and forgers of wood, stone, and metal were to a large extent the designers of the detail of much of the work they produced, guided and regulated by the master architect, and that the system of full-size drawings for every detail, as adopted by some of our modern architects, did not then generally if at all obtain. Granted that the sufficiently skilled craftsman, artistically as well as technically, can be found, it is surely far better that he should be allowed to put into his work the best that is in him, than that he should be reduced to the level of a mere facile machine. There must, of course, be a readiness of comprehension on the part of the craftsman of the feeling and spirit of the architect, so that harmony may result between the many parts and varied crafts in the building, and, on the other hand there must be, on the part of the architect, the ability to guide and direct and to convey his ideas and individuality to the craftsman. The necessity for this ability on the part of the architect emphasises the stress that Mr. Ernest George, in his presidential address to students at the Royal Institute on Monday night, laid on the importance for architects of freehand drawing. Not the freehand drawing of South Kensington nomenclature, but drawing from the cast and from the figure without tee-square and instruments. By this kind of freehand drawing a sketch on a half-sheet of notepaper, methodical and exact, would convey to the mind of the sufficiently skilled craftsman the intentions and thoughts of the architect as well as the full-size drawing. For such a sketch to be effective the architect must have ideas to express and the power of draughtsmanship necessary to give them expression.

The Stanley Technical Trade Schools, South Norwood, founded and endowed by Mr. W. F. Stanley, which, after two years existence, are now vested in the Charity Commissioners with an assured endowed income, are doing good work in training lads to become skilful, scientific, and artistic mechanics. The system of training adopted is the joint employment of schoolroom and workshop. In the schoolrooms the pupils learn to draw what in the workshops they carry into execution. By this means they learn to understand a drawing and to comprehend the interdependence of the several parts of that which they make, as well as the necessity for accurate compliance with the drawings. Although in these particular schools the aim of Mr. Stanley is chiefly to produce scientific workmen capable of raising England to the dignified position of the premier country in the world for the scientific exactitude and merit of its manufactures, the principles he has adopted seem to us eminently suited to the training of skilled craftsmen in the carrying out of architectural work. Although in the exigencies of modern manufacture, for the sake of speed and its consequent economy and for the attainment of the highest possible manual dexterity, it may be necessary to specialise to the utmost the actual work of each individual mechanic, the general realisation of the part that his special production plays in the whole and the necessity for the maximum of accuracy in his technique must make for efficiency.

"In the training of an architectural craftsman, drawing from the solid and drawing in the solid or modelling are of vital importance so that he may be able to understand what is meant in the solid by a drawing on the flat, and equally so for the architect student that he may be able readily, clearly, and exactly to convey by a simple drawing on the flat what he intends to be realised in the solid. It occurs to us to suggest that in the training of architect students at the Architectural Association and other institutions, as well as in the training of architectural craftsmen, it would be useful exercise for the students to make freehand drawings in design of ornament, and then for each of them to work from another man's drawing and model in the solid what was intended to be expressed. We do not intend to suggest this exercise in substitution of the modelling of a design by a student from his own drawing or from his own conception without a drawing, still less of the practising of modelling from a cast, but as complementary to all these. Thinking in the solid is of the utmost importance to an architectural student, and whilst modelling is a most valuable means of educating the power of such thought, it is not by any means the only one. The freehand drawing advocated by Mr. Ernest George should be enforced concurrently with geometrical drawing throughout a young architect's training in the schools. He should not be allowed to draw geometrically a single order without making also a freehand perspective sketch of that order. He should not be allowed to make the simplest design without drawing in perspective that design before he starts elevations or sections.

The education of craftsmen has been well initiated by the "higher elementary" system of training adopted at the Medburn Street School, East St. Pancras. Here boys are taught, besides drawing, how to make things—chairs, tables, cupboards, and minor articles of household use. They are taught to design wall-papers, book-covers and other practical applications of the drawing of ornament. The work of the school is, however, hampered by the limitation of age, as for the most part scholars are not allowed to remain in the school after the age of sixteen, whilst there appears to be no adequate provision for financial assistance to those whose parents are unable, without bursaries or scholarships, to keep their sons at school when they have reached the wage-earning age, thus crippling the development of those who belong to the class from which architectural craftsmen are mostly drawn.

Archdeacon Sinclair, at the induction of the Rev. H. C. Dimsdale as rector of St. Augustine's and St. Faith's-under-St. Paul's, advocated the retention of the City churches still left, against the views of those who urge that these monuments of our English Renaissance architecture should be pulled down, their sites sold, and the money thus obtained, as well as their emoluments, used for the erection and endowment of new churches in the more populous outer ring of London. The Archdeacon made a point of the value of the historical associations, the beautiful and dignified architecture of these old churches, and of their usefulness as homes of retirement for celebrated and honoured men who had borne the heat and burden of the day. From a mere monetary point of view the advantages of retention certainly seem rather dearly purchased, for the value of one church in the City would suffice for the erection and equipment of two or three in the suburbs. But money is not everything; and, besides, as far as our observation goes, the churches in populous parishes of 5,000 or 6,000 inhabitants that are already in existence do not seem to be able as a rule nowadays to attract full congregations, whilst as fresh suburbs come into existence there seems to be no great difficulty in the provision of fresh churches ample, to all appearance, for the requirements of their respective districts. It suits the iconoclasts to lay emphasis on the small congregations found in our City churches on Sunday, but they ignore the uses to which in some cases they are put during the week—a reason for their retention that might be made irresistible by further activity on the part of City incumbents generally.

The chief point of the report of the statistical officer to the housing committee of the London County Council is that it is not practicable to supply the entire need for working-class accommodation by municipal building, but that private enterprise must continue to supply the greater part of the accommodation.

THE ACROPOLIS OF ATHENS.*—I.

NOW that the whole surface of the Acropolis has been dug up clear down to the living rock, and the various treasures and remains sifted from the accumulated débris of ages, it is fitting that within the compass of one moderate-sized volume we should have an epitome of the discoveries made, the knowledge obtained, and the theories advanced as to the history, the purposes, and the form of the great masterpieces of Art in architecture and sculpture of which the Acropolis of Athens is the storehouse. Thanks, therefore, are due to Professor D'Ooge from all those who, though interested in the art of Athens, have not the time to devote to a complete study of the voluminous literature on the subject produced by many workers in the field of Greek archæology and research, written in several languages, and contained in magazines and papers of various societies, as well as in separate books. The volume now before us contains a record of the most interesting and important facts, and of the leading theories relating to the buildings and the other artistic and historical works of the Athenian Acropolis.

It is clear that Professor D'Ooge is not an architect and not perfectly acquainted with the technical language of architecture, so that architectural readers must not worry over some of his peculiar descriptions of, and allusions to, architectural features. When he speaks of "metopes of the older pediments," he must be understood to refer to metopes under the pediments, and even then not to exclude metopes in the friezes on the flanks. He speaks of "gable" when he means "pediment," and uses the two terms synonymously. He fails to distinguish as parts of the cornice between the corona and cymatium, and describes the latter as "the sima (*sic*) or cornice," not realising that the cymatium of the Parthenon is not a cyma; but, as Penrose pointed out, the only moulding in the Parthenon whose section is a pure and simple segment of a circle. It is rather amusing to read that the doorway of the Parthenon had "an upper sill, which served as a base for a large transom of lattice-work." Such curiosities of quasi-technical language are matters of small moment in a book of so much value, except that they lead to mystification when amateurs pick them up and fire them off in conversation with architects.

The American spelling "sima" for cyma is, by the way, particularly unfortunate, as σῖμός is used by Greek writers in the sense of concave as opposed to κυρτός, convex, and the cymatium of the Parthenon is convex.

Professor D'Ooge acknowledges his indebtedness particularly to Dr. Dörpfeld for much of the matter of his book, but he does not hesitate on occasion to differ from the theories of the great authority on Athenian archæology.

The relationship between the old Temple of Athena, discovered by Dr. Dörpfeld, the Parthenon, and the Erechtheion is one of the questions, and perhaps the most contentious, on which our author differs from the views of Dr. Dörpfeld. Professor D'Ooge assumes, we think quite unnecessarily, the existence of an older Erechtheion, which was the temple jointly of Erechtheus and Athena Polias. Later, that a separate temple was erected to Athena only, this being the old Temple of Athena, officially known as the Hecatompedon. Then the older Parthenon was commenced, before the Persian war, probably by Clisthenes, as a third temple to Athena. After the Persian war, he supposes that the assumed older Erechtheion and the old Hecatompedon were provisionally repaired, until they were superseded by the Parthenon and the Erechtheion, whose remains we see to-day.

Dr. Dörpfeld's view, as stated by Professor D'Ooge, is that the old Hecatompedon was restored after the Persian invasion and remained standing in the time of Pausanias and even to Roman times, notwithstanding that his own discoveries showed that the caryatide portico of the Erechtheion was built over the foundations of the peristyle of the old temple.

The generally admitted facts seem to be: first, that the old Temple of Athena—the Hecatompedon—was originally an amphiprostyle tetrastyle Ionic temple with an eastern chamber, divided into nave and aisles, a western chamber, and two small parallel chambers between the eastern and western ones; second, that a peristyle was subsequently added, probably in the time of Pisistratus, which Dörpfeld thinks was of the Doric order and Penrose believed to be Ionic; third, that the older Parthenon, commenced probably by Clisthenes, was in course of erection at the time of the Persian invasion and was destroyed by fire, the scaffolding furnishing fuel; fourth, that the present Parthenon, or new Hecatompedon, was erected in the time of Pericles, followed soon after by the present Erechtheion.

In the various theories superimposed on these facts, it seems to us that two other important points have been rather overlooked, the relationship of the Doric and Ionic orders and the multiplicity of cults of the goddess Athena.

It is too often forgotten that Doric and Ionic are distinct styles, the architectural expression of distinct peoples or tribes—Dorians and Ionians—who unitedly were components of the Greek nation—Panhellas. Plan types as well as columnar orders are marks of the two styles—distyle-in-antis of Doric, prostyle and amphiprostyle of Ionic. Attica was an Ionian settlement, the Peloponnesus a Dorian. That this was well recognised by the Greeks is shown by the inscription on the boundary pillar standing on the isthmus and described by Strabo.

With regard to the question of cult, it has been held on the one hand that the Parthenon was not the Temple of Athena Polias, and therefore not a cult temple; and on the other hand that the Parthenon was a cult temple, and therefore the Temple of Athena Polias. Both of these views ignore the fact of the multiplicity of cults of Athena. Just as in the Catholic Church to-day the Virgin-Mother is worshipped under a variety of titles, connoting various attributes and activities—as, for example, Our Lady of Loretto, Our Lady of the Seven Dolours, Our Lady Star of the Sea—so amongst the Greeks we have Athena distinguished as Polias, Parthenos, Promachos, Pallas, Nike, Hygieia, Ergane. There is therefore no improbability, but rather a practical certainty, that Athena was worshipped as Polias in one temple and Parthenos in another. Athena Polias, the protectress of Ionian Athens, would naturally have a temple of Ionic plan and Ionic order; Athena Parthenos and Nike, the virgin goddess who brought victory to the whole Greek nation, in a temple whose plan and orders symbolised the union of Dorian and Ionian—amphiprostyle but peripteral, with columns and mouldings of both Doric and Ionic styles. Athens aspired to be the head of the Greek confederacy, and so adopted the Doric style in the national temple, the Westminster Abbey of the Hellenes, the shrine of Athena Parthenos, whilst maintaining the local Ionic style for the Temple of Athena Polias, the St. Paul's Cathedral of Athens.

The plan of the old Temple of Athena, the Hecatompedon, is eminently suited for a joint temple of Erechtheus and Athena Polias, to which the allusions in the "Iliad" and "Odyssey" refer; whilst the Ionic style of its plan and order further confirm the view that it was the temple of deities of Athens.

When Clisthenes, the Alcmaeonid, influenced by his family connection with the Doric city of Delphi, commenced the older Parthenon, he would naturally advocate the use of the Doric style, and this would be readily adopted by the Athenians for the reasons we have already given. We cannot agree with the view of Professor D'Ooge that this older Parthenon, although Hecatompedon, was intended to "supersede" the old Temple of Athena Polias, to support which view he invents a purely supposititious older Erechtheion, but regard both

Digitized by Google

old and new Parthenon as temples for a distinct cult of Athena.

We think that Professor D'OOGE clearly proves that the term "opisthodomos" was not used, as Dr. DÖRPFELD argues, for any part of the old Temple of Athena, but for the western chamber of the Periclean temple, although this was also distinguished as the "Parthenon." The posticum alone cannot have been the opisthodomos, for it is not a rear chamber (opisthodomos), and was neither large enough to contain the treasures listed in the inventories that have come down to us, nor suitable for the business transacted in the opisthodomos, or for the lodgment of a royal visitor. The evidence of grillage is by no means sufficient to upset our view, as naturally the portico leading to the treasury would require a protective enclosure even if both it and the opisthodomos were not used for the storage of valuables.

Dr. DÖRPFELD's arguments on the question of the opisthodomos and the cult of Athena Polias are, of course, in support of his theory that the old Temple of Athena, the first Hecatompedon, was restored and remained standing until Roman times. We see no necessity for this theory to explain any records or allusions in Periclean or post-Periclean times, nor do we think either facts or probabilities support the theory.

It is probable that the old Temple of Athena received less injury during the Persian invasion than the work commenced by CLISTHENES, surrounded as this was by scaffolding. We should suggest as probable that the western chamber and the two treasure chambers of the old Athena temple remained in use during the building of the Periclean Parthenon and the Erechtheion, but that the eastern chamber was so far damaged that it was pulled down, together with the peristyle. The position of the caryatide portico and its slight eccentricity with the axial line of the north portico of the Erechtheion seem to us presumptive evidence of our suggested probability. When the Parthenon and the Erechtheion, so far as it was built, were completed there was no longer any necessity for preserving or restoring the old Athena temple, as the Parthenon, in our view, contained the treasury in its "opisthodomos," and the Erechtheion provided a home for the cult of Athena Polias. We thus go a little further than Professor D'OOGE, who suggests that the old Athena temple was temporarily restored until the Parthenon and Erechtheion were built. We should limit this restoration or reparation and use as we have above suggested. We agree with Professor D'OOGE that the famous oath quoted by LYCURGUS and other literary evidence is strongly against the probability of any complete restoration or rebuilding of the old Athena temple.

(To be continued.)

STEELWORK.—IV.

By C. V. CHILDS, A.M.I.C.E.

RETURNING to the consideration of the steel frame, it is a far more difficult matter to design the steelwork for an English building than for one of those enormously high "skyscrapers," which in the majority of cases means nothing more than piling similar floors one on top of another. In the latter case the designer has only one floor to deal with at a time, and on bringing the reactions of the girders of any one floor to the points of the column supports all the weight on that floor is accounted for, and it only remains to tabulate the column loads floor by floor. On the other hand, in an English building with girders of the upper storeys bearing on the walls a great deal of care has to be exercised in seeing that these are all properly taken care of in designing the girders carrying these walls; also in seeing that the pressure on the brickwork or masonry is in no case excessive.

Then there are in all probability all sorts and conditions of chimney-stacks to be provided for, to say nothing of heavy stone cornices, in some cases six or more feet thick. The loadings on the girders for an English building are far heavier and more complicated than for a steel skeleton frame, except possibly in the case where the system is adopted of carrying the columns in the external party walls on cantilever girders at the basement floor in order to bring all the foundations within the limits of the building line. It may be mentioned that the regulation thickness of party walls in London makes this system unnecessary, though in one case at least—viz. the Ritz Hotel, a building on the steel-frame principle—this method has been used.

While on the subject of what is a necessity in American and not so in English practice, the lateral wind bracing may be referred to. The enormous height compared to the width of the base of a "skyscraper" makes this an important factor; it is also rather a complex problem.

The building itself is practically a cantilever, anchored by its own weight to the ground; what correspond to the flange stresses are easily provided for by increasing the areas of the stanchions in the external walls. The difficulty is in regard to the lateral bracing, corresponding to the web of an ordinary girder; in the lower storeys the strains are so enormous, and the space in which to deal with the bracing is so confined owing to openings for windows, doors, &c., that it is well-nigh impossible to put in the amount of bracing theoretically demanded.

The practice used to be to consider the bracing required for one or two storeys sufficient for all the floors; this was no doubt enough to guard against distortion during building operations. The probability is that the high buildings depend chiefly on the walls for safety against distortion by wind pressure; these would act as the diagonal, and the floors as the vertical, braces in an ordinary horizontal lattice girder; distortion, in order to take place, would first crush the panels of the walls contained between the girders and the stanchions; for this reason it is essential to carefully grout between the stanchions and the walls in order to make the bond between them secure.

Sometimes the question is asked, What is the effect on the framework that may be caused by the expansion and contraction of the steel, due to changes of temperature? In almost every case in America the connections of the girders are rivetted in position, so that the framework is as rigid a structure as a bridge.

In the case of the Carnegie Building, in which the whole of the steel framework was erected before the walls were built, the movement caused by the sun striking on one side of the building, before the other part, was quite a considerable amount, and heavy temporary timber braces had to be employed to keep the framework from twisting out of position.

When the walls are built and the building is occupied, no doubt the internal warmth helps to keep even the stanchions in the exterior walls at a more even temperature. Then again other materials are also similarly affected, so that the variation in contraction and expansion between the different materials is not sufficiently large to cause any serious damage.

The fact that brickwork expands and contracts, though to a less extent than steel, is seldom considered; while in the case of concrete the coefficient of expansion for changes of temperature is almost exactly the same as that of steel.

This fact is seldom realised in building construction, but in the case of large masses of concrete, such as for retaining walls of any great length, unless provision is made by providing expansion joints, trouble is likely to occur, either on account of the concrete cracking or the walls buckling.

A curious instance of this once occurred in the writer's practice. A large area of mosaic pavement was giving considerable trouble, owing to the pavement and the concrete vaulting continually cracking, causing the water to leak through into the vaults beneath. The paving formed a series of terraces, ending at the bottom in a flight of steps, in which the steel cross joists ran at right angles to the arches of the vaults.

The only effect of cutting out and making good the cracks seemed to be to push the steps farther and farther down hill, so much so that the spandril walls had slid along their plinth.

Apparently what was taking place seemed to be that the movement was due to the expansion of the concrete in warm weather, but in cold weather the concrete arches were not sufficiently strong to pull the other portion, including the steps, back into place again. By cutting through the concrete floor over a cross wall and putting in a lead gutter the trouble was almost entirely rectified. It is not often that such a clear case of the effect of the expansion and contraction of concrete under variations of temperature is forced upon one's attention.

Speaking from personal experience, the engineer, used to and fresh from the designing of American steel skeleton con-

Digitized by Google

struction, is inclined to draw invidious comparisons and imagine that the "old country" is indeed old and not up to date, overlooking the fact that the conditions are entirely different, and that it is not ignorance, but the difficulty of altering legislation, especially where public safety is concerned, that checks the development of innovations.

Here the Board of Trade and municipal regulations are perhaps over careful and slow to move in new directions, and retard new enterprises; one has only to call to mind the difficulties that the motor-car industry had to contend with in its infancy before it was allowed the use of public roads. So, too, the projectors of local public works, such as tramways, &c., need in America only apply to the town hall, instead of having to secure a special Act of Parliament to obtain sanction for their schemes.

All the main features of the steel-frame building, however, have been adopted and become general in English practice as far as they are economically adaptable. Economic considerations govern all business enterprises. That the steel skeleton under existing conditions in London is far from economical one typical instance may be given. The proof of the pudding is in the eating, or in the doctor's bill afterwards, and this is not an isolated case. For a large business premises now erected in Oxford Street two steel designs were prepared, one on the approved lines of the American steel skeleton framework, and prices were obtained from the Continent for this design. In the other case the design prepared by the writer was what might be called a semi-steel framework—that is, every main-wall or floor girder in the building was carried on stanchions from basement to roof; the exterior walls were carried at the first floor level, except the main front, which being very massive was carried in three sections, at the first, third and fifth floor levels; the internal walls were sufficiently strong to support themselves, as well as the end bays of the floors. The price for this latter design, made in London and of English steel, was less than half that for the skeleton design—a saving of over 25,000*l*. Other cases might be instanced in which the saving showed an even greater proportion.

Beginning at the foundations, one may enumerate and consider separately the various features which have been adopted into English practice.

Grillages.—These, as already stated, were originally designed to overcome the difficulties due to the subsoil at Chicago. They were found to be equally valuable as a means of spreading the pressure over the footing area in all cases where the load on the stanchion was considerable. Formerly in England the loads on the stanchions were comparatively light, but of late years the steelwork has been called upon to fulfil more and more exacting requirements. The York stone, set on top of the concrete base, was amply sufficient when the loads were only moderate; now, in a modern design, the loads on the stanchions may amount to some hundreds of tons each. This would require a very considerable thickness in the concrete and a corresponding depth of excavation; hence the adoption of the rolled-steel joist grillage has become almost universal under stanchions carrying upwards of fifty tons. In London, except in unfavourable localities, such as made-up ground, it is usually safe to keep within a limit of three tons pressure per square foot on the ground. The following table may be found convenient in determining the sizes of the grillage joists under the above conditions:—

Stanchion Load in Tons.	Length of Stanchion Base.	Grillage Joists.		Area of Concrete Base, Square.
		Top Tier.	Bottom Tier.	
50 to 75	1'-8"	3-8" × 5"—4'-0"	None.	5'-0"
75 to 100	Do.	3-10" × 5"—5'-3"	None.	6' 0"
100 to 125	3'-0"	3-8" × 5"—5'-6"	4-8" × 4"—5'-9"	6'-6"
125 to 150	Do.	4-8" × 5"—6'-6"	5-8" × 4"—6'-9"	7'-6"
150 to 200	Do.	4-10" × 6" - 7'-6"	5-10" × 5"—7'-9"	8'-6"
200 to 250	Do.	Do.	5-10" × 5"—8' 9"	9'-6"
250 to 300	3'-6"	5-10" × 6"—9'-3"	6-10" × 5"—9'-3"	10' 0"
300 to 350	Do.	Do.	6-10" × 5"—10'-0"	10'-9"
350 to 400	Do.	5-12" × 6"—10' 6"	7-12" × 5"—10'-9"	11'-6"
400 to 450	Do.	Do.	7-12" × 5"—11'-6"	12'-3"

From the above it will be noticed that the concrete base under a stanchion carrying upwards of 400 tons (allowing 8 inches underneath the grillage and 1 inch for grouting under the stanchion base) need not exceed 2 feet 9 inches in depth.

Cast-iron distance pieces should be used to stiffen the webs of the joists immediately under the heavier stanchions, or the stiffeners should be rivetted to the webs. It is also advisable to rivet the top and bottom flanges of the joists in each tier together, with four flats 6 or 8 inches wide, two at each end; the joists are then ready spaced for setting position. It is usual to allow for ½ to 1 inch space for grouting between the top flange of the uppermost tier and the base of the stanchion, so that the stanchion can be set properly plumb.

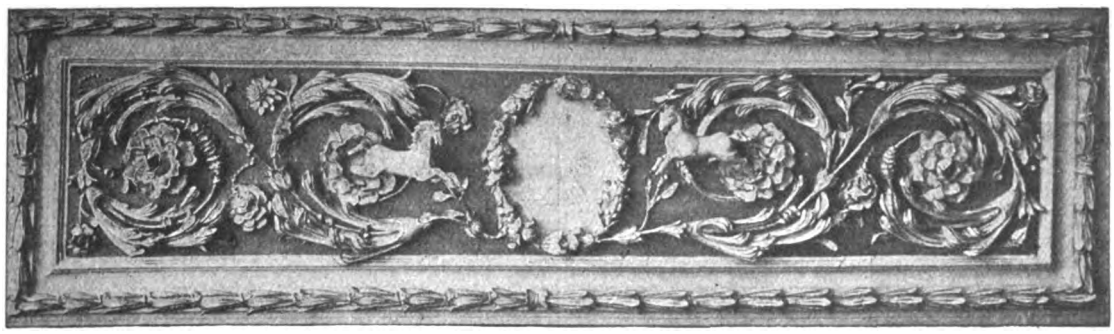
The easiest method of doing this is to use four small wedges under the corners of the base plate. After the stanchion is set perfectly plumb by means of these wedges, it is carefully raised sufficiently to spread the grouting underneath it and then dropped back exactly in the same place over the wedges, which should not be removed till the grouting; but if bolts are used, they should not be firmly down bolts are hardly necessary, the base being bedded in the grouting; but if bolts are used, they should not be firmly embedded in the concrete before the stanchions are erected, as this is apt to cause trouble if the holes in the base plate do not come exactly over the bolts. This may seem obvious, but the concretor is often not over-concerned about the troubles of the steelwork erector. A variation in the grillage may advantageously be made for the smaller stanchions by rivetting the top tier, in the form of two steel channels, to the shear plates of the stanchion base.

WINCHESTER CATHEDRAL.

THE cathedral works and wants completed or requiring attention are set forth in a report from Mr. Jackson, R.A., who estimates a total outlay of 99,000*l*. The previous estimate of October 1907 put the outlay at 86,806*l*. It is interesting to note, as a proof of the care used for the chantries, that the magnificent one of William of Waynflete has been cleansed of dust without the least alteration or addition, and now, thanks to Magdalen College, Oxford, which the Bishop founded, this grand chantry stands in all its pristine beauty. The splendid chantry of Cardinal Beaufort has been similarly dealt with, the only new work being the replacing of pinnacles, which have been missing for years. Mr. Jackson says this is his final survey of the building, and he describes in detail all that is necessary to be done in the way of restoration. He adds, however, that in overhauling the building several repairs have presented themselves as requiring attention, which fall rather under the head of ordinary reparation of the fabric.

The lead roofs of the south side of the presbytery, the choir aisles, the tower, the north nave aisle, and both aisles of the south transept will need before long to be partly or entirely recast and relaid, and the parapets of the north nave aisle and clerestory will need repairing to a considerable extent, as has been done in the corresponding parapets on the south side.

The ironwork in the nave roof should be painted, and all the nuts seen to and tightened up.



These matters are not of so pressing a nature as the others that precede them, but they must not be overlooked in estimating the work that lies in view.

The Waynflete chantry has had the supporting wall strengthened, as already described. The crack between the Norman and Early English building went through this chantry, and caused a serious fissure across it. This has been repaired, and the whole monument has been cleaned by simply washing it, but, of course, no tool has been applied to the surface.

The chantry of Cardinal Beaufort has not suffered so much. The support below has been strengthened, as in the case of the Waynflete chantry, and the pinnacles, of which many were missing, are being restored. The report concludes:—

I have gone carefully into the estimate of the various works mentioned above as still necessary to the security of the fabric, in consultation with the contractor, Mr. Thompson, of Peterborough, and I estimate that the total sum required will be little less than 99,000*l*. The prices are based on the experience of cost hitherto incurred in each part of the work, and though, of course, they are to a certain extent conjectural, I fear that the total expense will not fall short of the sum we have arrived at.

PLASTER DECORATION.*

IF there is to be a revival of plaster-work in this country the handsome volume by Mr. G. P. BANKART entitled "The Art of the Plasterer" should prove of inestimable service. It is difficult to believe that plaster will never regain the importance that it once enjoyed. Indeed, during the last half-century there have not been wanting signs that this time-honoured form of decoration, which was employed in B.C. 1800 in the Palace of Knossos—not to mention B.C. 3500 in Mesopotamia—may take once more a prominent place in public and domestic architecture. But Mr. BANKART appears to have little or no hope of any emulation of the best work of the past so long as the existing conditions continue, when "servile workers attempt to realise the mathematically delineated visions of professional men set up in offices, men whose ideas were borrowed from this place or that, and whose thoughts had mostly been stolen from other countries during various holiday sketching tours."

The author seems to have had some difficulty in keeping his work within reasonable bounds. He has been able, however, to escape the allurements of a detailed historical account of his subject in order to treat at length of past and present work in this country. Chapters on Classic and Italian Renaissance work are, he explains in the Preface, included, as some slight knowledge of these is necessary to a right understanding of the development of English work. Plaster-work in France and other European countries and in the East is only lightly touched upon, as it was felt that these branches of the subject required separate treatment. A passing reference is, however, made to French work, sufficient to indicate that it served as the connecting link between the original Italian and the English schools.

Plaster-workers have, as we have indicated above, an inspiring past history. We need not go further back than Ancient Greece, where stucco was in almost universal use and where it was carried to a very advanced stage. It was the immediate predecessor of marble. The victorious Romans were at first as strongly influenced by Greek feeling in their stucco-duro decorations as in other forms of art production. VIOLLET-LE-DUC states that they employed it very frequently both for public monuments and private dwellings. Its use was passed down to the Gauls, though in an inferior form, and there is not, he says, a single Gallo-Roman building in which the remains of stucco-coatings, polished and painted, are not found. In the sixteenth century it became once more an important feature of architectural decoration owing to the discoveries by Cardinal GIOVANNI DE MEDICI in 1488, while excavating on the site of the Baths of Titus, of walls covered with fine paintings and stucco-work. VASARI gives the artistic credit to MORTO DA FELTRO, and he was followed by ANDREA DI COSIMO, who introduced the practice of covering the front of buildings with an intonaco of plaster wherein the black of ground charcoal or burnt straw had been mixed. GIOVANNI DA UDINE, the assistant of RAPHAEL, rediscovered the way to make stucco-duro, and in 1513 was commissioned to carry out the decoration of the Loggie of the Vatican, where he had the assistance of GIULIO ROMANO. These two artists also co-operated on the beautiful Villa Madama. Among the assistants of GIULIO was PRIMATICCIO, who in 1531 went to Fontainebleau at the invitation of FRANCIS I. of France. During his forty years work at that palace he firmly established plaster-working in France, and indirectly was a potent influence in its introduction into this country, for HENRY VIII. was determined that Nonesuch Palace should eclipse any French royal residence.

The guiding spirit in the stucco decoration of Nonesuch appears to have been a Florentine named TOTO DEL NUNZIATA, or ANTONY TOTO, who, in 1539, one year after the commencement of the building, was appointed sergeant-painter to the King. He was assisted by many other Italian modellers. JOHN EVELYN visited the ruins of the palace in 1666, and wrote:—"I took an exact view of the plaster statues and bas-relievos inserted between the puncheons of the inside walls of the court, which must have been the work of some celebrated Italian. I much admired how it had lasted so well and entire from the time of HENRY VIII., exposed as they are to the air; and pity it is they are not taken out and placed in some dry place—a gallery would much become them. They are mezzo-relievos the size of life." The royal patronage was soon followed by that of English noblemen, and it was not long before native craftsmen were working side by side with the foreigners. Mr. BANKART says:—

In the times of Edward VI. the English plasterer had pretty well learned from these foreigners the art of working in stucco, and earned his 11*d.* a day, while his brother painter received only 6*d.*, or, when lucky, a penny more. In 1547, or thereabout that time, an English stuccoist who had travelled in Italy, Charles Williams by name, is found working in England. He most probably had assisted in the work at Fontainebleau and also at Nonesuch. In 1547 Charles Williams wrote to Sir John Thynne, who was then engaged in building Longleat House, Wiltshire, and offered Sir John his services in supplying internal decorations "in the Italian fashion." At Longleat are two letters from Sir William Cavendish and his wife, asking for the use of this "cunning playsterer, whom they have heard had made dyvers pendants and other pretty things, and had flowered the hall at Longleat," to do like work for them at Hardwick. The old hall at Hardwick, now in ruins, was being built from 1567 to 1590, but was never completed. On the walls of the Giants' Chamber are to be seen at the present time the remains of a modelled frieze of excellent workmanship, undoubtedly the work of Charles Williams. . . . It is to be regretted that the ruins of the old hall are now in an extremely dangerous condition, so much so that there is risk in pursuing one's studies there. Charles Williams established a school of English stucco modellers. The coloured frieze in the state room of the present Hardwick Hall is probably the work of this school, executed between 1590-97, and besides being coarser in workmanship, it is inferior to

the earlier example. . . . The Englishman left to himself tended towards the burlesque, while the Italian, on the other hand, came as near to the perfection of form as he was allowed to by the material.

Native talent was not content with mere imitation, and by the end of the sixteenth century began to experiment with a coarser and more indigenous material than stucco-duro, viz. the ordinary lime and sand and hair with which the walls were coated. The artist was usually the local plasterer or mason, who evolved his own patterns for his parge-work. One of the best known examples is Sparrow's House, Ipswich. Mr. BANKART in his remarks on it does not mention as to how far the work now seen on the exterior is unrestored. It can scarcely be possible that after three centuries the modelling should have remained so sharp. The majority of timber-built houses in London up to the time of the Great Fire were enriched with this parge-work; but few remain, and none of these are included among the numerous photographic examples given in the volume. The illustrations have been collected from many different counties. It would appear that the human figure was very rarely introduced into exterior panels, and only occasionally into interiors.

The English school of plaster-work gradually superseded the Italian, French, and Dutch methods, both in the material and in the design. As the author points out:—"The great spacious halls and chambers of France and Italy necessitated a more ambitious treatment than the simple homes of the English people. The rooms were of less height and smaller in size than those of our neighbours, and the scope of the artist in plaster had corresponding limitations, of course; so no more was attempted at first than easily repeated patterns of panelling formed by moulded ribs of plaster. The panels were small to begin with, growing larger as time went on. The mouldings were of simple section, the earlier examples being made up of few members, chiefly groupings of beadings, ovolos, and fillets." The several photographs of Plas Mawr, Conway, prove that by the latter part of the sixteenth century the artists had acquired considerable freedom and confidence, animal forms being introduced with great success for heraldic purposes, though the ceilings are somewhat plain with prominent ribs. The work attained its zenith by the first half of the seventeenth century. The plasterer, we are told, received some ideas from the patterns of the brocades and embroideries of Persia and Italy and from the tapestries and needlework of the ladies. A striking instance of this is to be seen in the ceilings at Burton Agnes Hall, Yorks. The forms of their figures and ornaments, the growth of their floral sprays and sprigs, and the design of their running patterns in borders are extremely similar in the two arts.

The panellings gradually developed after the manner of the radiating ribs and fan-vaulting, and is known as the Pendentive System. The best example is said to be the Fish Room at Audley End, which dates from 1615. This system was superseded by a geometric arrangement of ribs, which differed from the earlier arrangement in its not being limited to straight lines.

Plaster-work was little known beyond the Tweed until the end of the reign of JAMES I. It would seem as if it was more of an exotic than in England. It was introduced into the castles by Flemish and Italian artists, and remained in the dwellings of the wealthy. The five illustrations of portions of ceilings in Holyrood Palace corroborate the remark that "the delicacy of the technique is most beautiful, and will bear the minutest scrutiny," and justify the legend that they were the work of gentlemen modellers, though perhaps they are not too painstaking for any band of amateurs.

The earliest important example of Irish plaster-work is that in the Royal Hospital, Kilmainham, Dublin, which was designed by WREN, and executed in 1680. It is shown on four full-page plates. With the exception of that building and another in Tipperary there are, we are told, no examples of Irish work which were not of the eighteenth century and none outside Dublin.

In the chapter entitled "English Plaster-work of the Later Renaissance," great importance is attached to INIGO JONES as having introduced an entirely new manner of ceiling decoration from Italy after his visits about 1604-5 and 1613-5, and whose influence endured for two centuries. The altered conditions are thus described:—"From the time of his coming, and after, there was none of the freedom of craftsmanship that existed in Queen ELIZABETH'S time, nor had he the skilled craftsman to help him out. His men were expected to carry out his instructions implicitly. No more will be heard of the old independence of craftsman or master builder, for the architect had to be first." This new attitude of the architect was continued by WREN, though he allowed very wide latitude to GRINLING GIBBONS. Mr. BANKART considers that, with all WREN'S genius as an architect, his ornament was never quite free from the spirit of the amateur, and that it became more and more meaningless. Detailed attention is given to the various City churches where WREN gave immense scope to the plaster-worker. After his death the craft rapidly degenerated. The Brothers ADAM were able to strike out on another line, even if their ideas were borrowed from Italy. It certainly can be said with truth that their ceiling decoration was graceful and refined in design, delicate and subtle in modelling.

The last chapter of the volume is devoted to "Modern Plaster-work." Mr. BANKART has the uncomfortable conviction that the time is out of joint. He blames the architect chiefly for the present unsatisfactory conditions, as being the man who designs without technical knowledge while using wrong patterns, and dictates without personal acquaintance with the material. "Why is the plaster-work of the nineteenth century so uninteresting, bad, and uncouth?" asks the author. The explanation offered is, "Because the calling is divorced from pleasurable and legitimate production. Besides which, in the completeness of this divorce from the craft, the opportunity of self-expression is denied to the worker, whatever his talent is." The author justly protests against details suitable for wood or stone being moulded in plaster, and illustrates his idea by means of diagrams as to right and wrong sections for mouldings. Valuable advice is given to the future designer as to the use of his new materials and the adaption of his design to new conditions. An additional chapter is entitled "Notes addressed to Students and Apprentices."

This volume (of which a copy has been accepted by His Majesty the KING) ought, as we have already said, to be a powerful agent in bringing about a new Renaissance in plaster-work. The ground is, we believe, more ready for the sowing of the seed than Mr. BANKART appears to imagine. No doubt he must find it difficult to be optimistic when he compares the work of the past with the present. But his labour will not have been in vain if it fires the rising craftsmen to emulate—but not to imitate—the splendid achievements of their distant predecessors. It will be a great day for architecture when that ambition is general, and not, as at present, confined to one or two artists who employ plaster for a medium.

WOODWORK.

THE following lecture, illustrated by lantern photographs, was delivered on Wednesday evening last at Carpenters' Hall, London Wall, E.C., by Mr. E. Guy Dawber, F.R.I.B.A. :—

The subject of my lecture this evening—the historical growth of design in woodwork—is one of especial interest to English craftsmen.

After the admirable addresses by Mr. Schultz on "Reason in Building," it may be useful to follow the broad changes that took place throughout the past centuries in the forms and design of woodwork.

Some may argue that this partakes too much of mere archæology and antiquarianism, and that it is out of place to-day, but my answer to this is that every craftsman should know something of the rich heritage bequeathed to him by his ancestors, and that a study and analysis of the old methods of building and the proper use and application of materials will help us considerably in the solution of our own problems to-day.

England has always been a timber-using country, and its people from the earliest times have been accustomed to its employment in the building of ships and especially in the use of the bow and arrow.

Woodwork in this country was more varied in the purposes to which it was applied than that of any other, but whether this was owing to our insular position, our skill in naval architecture, or the fact that we had the good fortune to possess some of the best of European timber, it is certain that the buildings our ancestors erected are remarkable for the beauty and variety of their woodwork.

If there is one feature above all others which distinguishes the craftsmen of this country it is the skill they showed in the science and practice of carpentry, and we are indeed fortunate in possessing so many examples of their workmanship.

The subject divides itself into several heads, some of which we can only touch upon.

Firstly, the use of woodwork in roofs, spires, houses and barns, ceilings, floors, staircases, doors and windows, &c.; and secondly, the use of woodwork in furniture, screens, seats and stalls, pulpits, presses, chests and so on.

Of woodwork executed before the twelfth century we have few or no examples, but it probably did not differ much in design and character from that of the tenth and eleventh centuries, at least judging by representations in early illuminated manuscripts.

Up to the sixteenth century the Gothic woodwork and fittings in both churches and houses were all of what we should call an ecclesiastical type—the ordinary style of the day; and for more than three centuries there was absolute connection between wood and stonework, both in design and detail.

This is natural enough when we recollect that the masons who built the walls of the church, the house or the barn, and the carpenters and joiners who made the interior woodwork and furniture, were probably natives of the same village and brought up with the same ideas; and allowing for differences of technique, the simple patterns of the stonemason did very well for the timberwork.

Therefore we find the woodwork of the church identical with that of the house, and it was only after the Reformation and the introduction of the Renaissance and Classical detail that the ecclesiastical spirit in woodwork died out, and what we associate to-day with Domestic work took its place, but though to-night we are dealing with it separately, it must not be forgotten that throughout all periods it formed part of the actual structure.

From the time of the Conquest, our English masons were producing a series of wonderful buildings all over the country, many vaulted with stone, culminating in Henry VII.'s Chapel at Westminster, and King's College Chapel at Cambridge, but at the same time, whether owing to our national pride, or the skill and ability of our carpenters, in all their smaller buildings a preference was shown for timber roofs instead of the more usual stone ones.

Possibly, in certain districts this might have been due to the difficulty of obtaining good building stone, and they had of necessity to fall back upon the only other local material at hand.

During all this period when the art of masonry was developing to such a wonderful degree, woodwork to a large extent was more or less imitative, if we except the noble series of timber roofs, a large number of which still fortunately remain.

These exhibit a fertility of design and soundness of construction truly astonishing, and place the craft of the carpenters of the Middle Ages in the foremost rank.

The simplest and earliest description of roofs doubtless consisted of two rafters pitching against each other. Owing to its tendency to thrust out the walls, this formation soon led to the introduction of the tie beam, which in conjunction with the rafters gives us the simple form of roof still in use to-day.

We find this throughout the Middle Ages in domestic as well as ecclesiastical work, often with a king-post in the centre, treated as a shaft with moulded cap and base, and curved braces on either side.

Again, in certain districts we note a remarkable similarity in the design of the roofs.

The hammer-beam roofs of the eastern counties, the trussed rafter-roofs of Kent and Sussex, and the waggon-shaped roofs of the West of England, all show the influence of the fashion set, perhaps by some strong personality, or the abundance or limitation of the material at hand.

Many of the old tithe barn roofs were of admirable design, with centre and side aisles, the one at Harmondsworth in Middlesex, dating from the early fifteenth century, being a particularly fine example.

The well-known roof over Westminster Hall, one of the earliest (1397), is undoubtedly the most magnificent example in this country. This great arch of timber thrown across such a vast span is indeed a noble conception, superbly carried out and constructed.

These timber-roofs, the wooden screens to the roods and chapels, the stalls and benches, the doors and panellings all based the motif of their design and decoration on the cusping and tracery of the stone windows, and unhesitatingly copied and adapted them.

We notice the various phases of design succeeding each other in exactly the same way as among the contemporary workers in stone, the main difference being that the work in wood is generally thinner, flatter and more delicate, and it is useful to bear this in mind because it helps to simplify the earlier part of our subject.

The use of timber again in the framework of buildings was very common; and in conjunction with stone and brick formed in timber growing districts the chief material of their entire construction.

All, however, whether in churches, houses, stables, or barns, were constructed on the same principle, and with the same solidity and general goodness of effect.

You can see a group of these wooden houses in Holborn to-day, and in Kent, Sussex and Surrey numerous examples still remain.

The very beautiful Guildhall at Lavenham, in Suffolk, about the latter half of the sixteenth century, is very characteristic of the eastern counties, and is an admirable example of mediæval carpentry.

The lavish and almost wasteful use of timber in the construction of the buildings in the West of England is accounted for by the existence of the large forests known to have flourished there in the Middle Ages, at a safe distance from the iron-smelting works which depleted the woodlands of Sussex and the great shipbuilding yards of the South of England. Again, a very marked characteristic of western design as compared with the houses of the East of England is the elaboration of ornamental forms in the timberwork itself—more apparent the further north we travel, and culminating in the ingenious devices of Lancashire and Cheshire.

The old carpenters used the timber as it came to hand, crooked or straight, but always with an eye to the picturesque as well as the useful; and we see this especially in the designs contrived by using the bent and twisted pieces of wood in the curved braces and filling pieces in these half-timbered houses of the West of England.

The timberwork generally of the West is cruder and somewhat coarser in character than that found in the East of England and the Weald of Kent, and Mr. Reginald Blomfield attributes this to the presence of the Flemings, who doubtless taught the English builders some of their admirable skill in craftsmanship.

(To be continued.)

The Local Government Board have just sanctioned a loan for the cost of pulling down the Georgian town hall at Newbury, building additional municipal offices and widening Mansion House Street, at present a narrow thoroughfare with dangerous corners leading from Bridge Street to the Market Place. The erection of a new commodious town hall, with all the latest improvements, will be in hand a little later on.

NOTES AND COMMENTS.

Antiquities and art treasures are in Italy a matter of national concern, and the Government regulates archæological research and provides a considerable portion of the funds. Archæology and art are in fact included within the province of the Ministry of Education, and Signor Rava has recently taken the opportunity of summarising the results of the last few years. Amongst the treasures added to the national collections have been the frescoes of Luini, the *Discobolos* of Castello Porziano, the *Magdalen* of Pietro di Cosimo, the *Annunciation* of Messina, the *Angel* of Penacchi, the bronze ornaments of sunken galleys from Nemi, and the collection of the antiquities of Palestrina. In the field of excavation have been the discoveries in the Roman Forum and Palatine Hill, of the Roman theatre at Turin, at Ostia, and in Egypt and Crete. The finances of exploration work are, of course, aided by the fees charged for admission to view, but whereas in the past half of the fees has been appropriated by the Ministry for general antiquarian purposes and the purchase of works of art, it is now proposed that each gallery, museum or monument shall be credited with the whole of the fees it earns up to a certain sum. This is, we think, as it should be, for no one objects to paying a fee to be allowed a sight of the Roman Forum, knowing that he is thus contributing to some small extent in the cost of discovering and preserving the treasures it contains.

Whilst we do not wish to enter into any political discussion on the merits of Free Trade and Tariff Reform, we think that the report of the Tariff Commission on the engineering industries, and particularly electrical engineering, closely connected as these are with the building trade, is one that should be studied by all who desire to form an unbiassed opinion. That British industries have not prospered of late as have those of some of our foreign competitors is a fact patent to all. How far this is the result of hostile tariffs and protection can be learnt from the evidence published in this report.

The exhibition of work by the students of the Camberwell School of Arts and Crafts shows that good results are being obtained from the training given at this institution and its allied centres. The one art in which this school fails comparatively is architecture, and in this respect it is on the same level with the majority of polytechnics or technical schools in London as far as our experience goes. Carving, modelling, lead and plaster work, cabinet work, jewellery, dressmaking, embroidery, pottery and many other crafts are excellently taught and intelligently learnt, and it would be more fitting, in our opinion, to style this a school of artistic crafts.

Professor Sayce has made an important discovery of the true site of the ancient city of Meroë, which he has located about half-way between Atbara and Khartum. Feeling dissatisfied with the dictum of Caillard, who in 1821 declared that the temples at Naga marked the site of Meroë, he made researches around the pyramids near Kabushia and has been rewarded by finding unquestionable signs and remains of a ruined city, including the great wall of the inner defences and the remains of the Temple of Ammon, mentioned by Strabo, together with part of the avenue of rams leading up to the temple. Professor Sayce has also found a statue of a king, life-size, and an important slab with Greek inscriptions, as well as scarabs, seals, and pottery of various dates from 700 B.C. to 300 A.D. The chief importance of the correct location of Meroë lies in the fact that it forms the centre from which can be measured the known distances of buried cities of ancient Ethiopia mentioned by early historians, and their approximate situation can be thereby determined.

It should not be forgotten that although a sample of Portland cement complies with the requirements of the British Standard Specification when tested with "dry standard sand," it does not necessarily follow that it will give as good a result with the sand that may be used on a particular building. This was forcibly illustrated at a recent meeting of the Royal Victorian Institute of Architects, when it was shown that the Leighton Buzzard sand—our standard—gave as a result one-third more strength than the Nepean River sand, used as a standard in Australia.

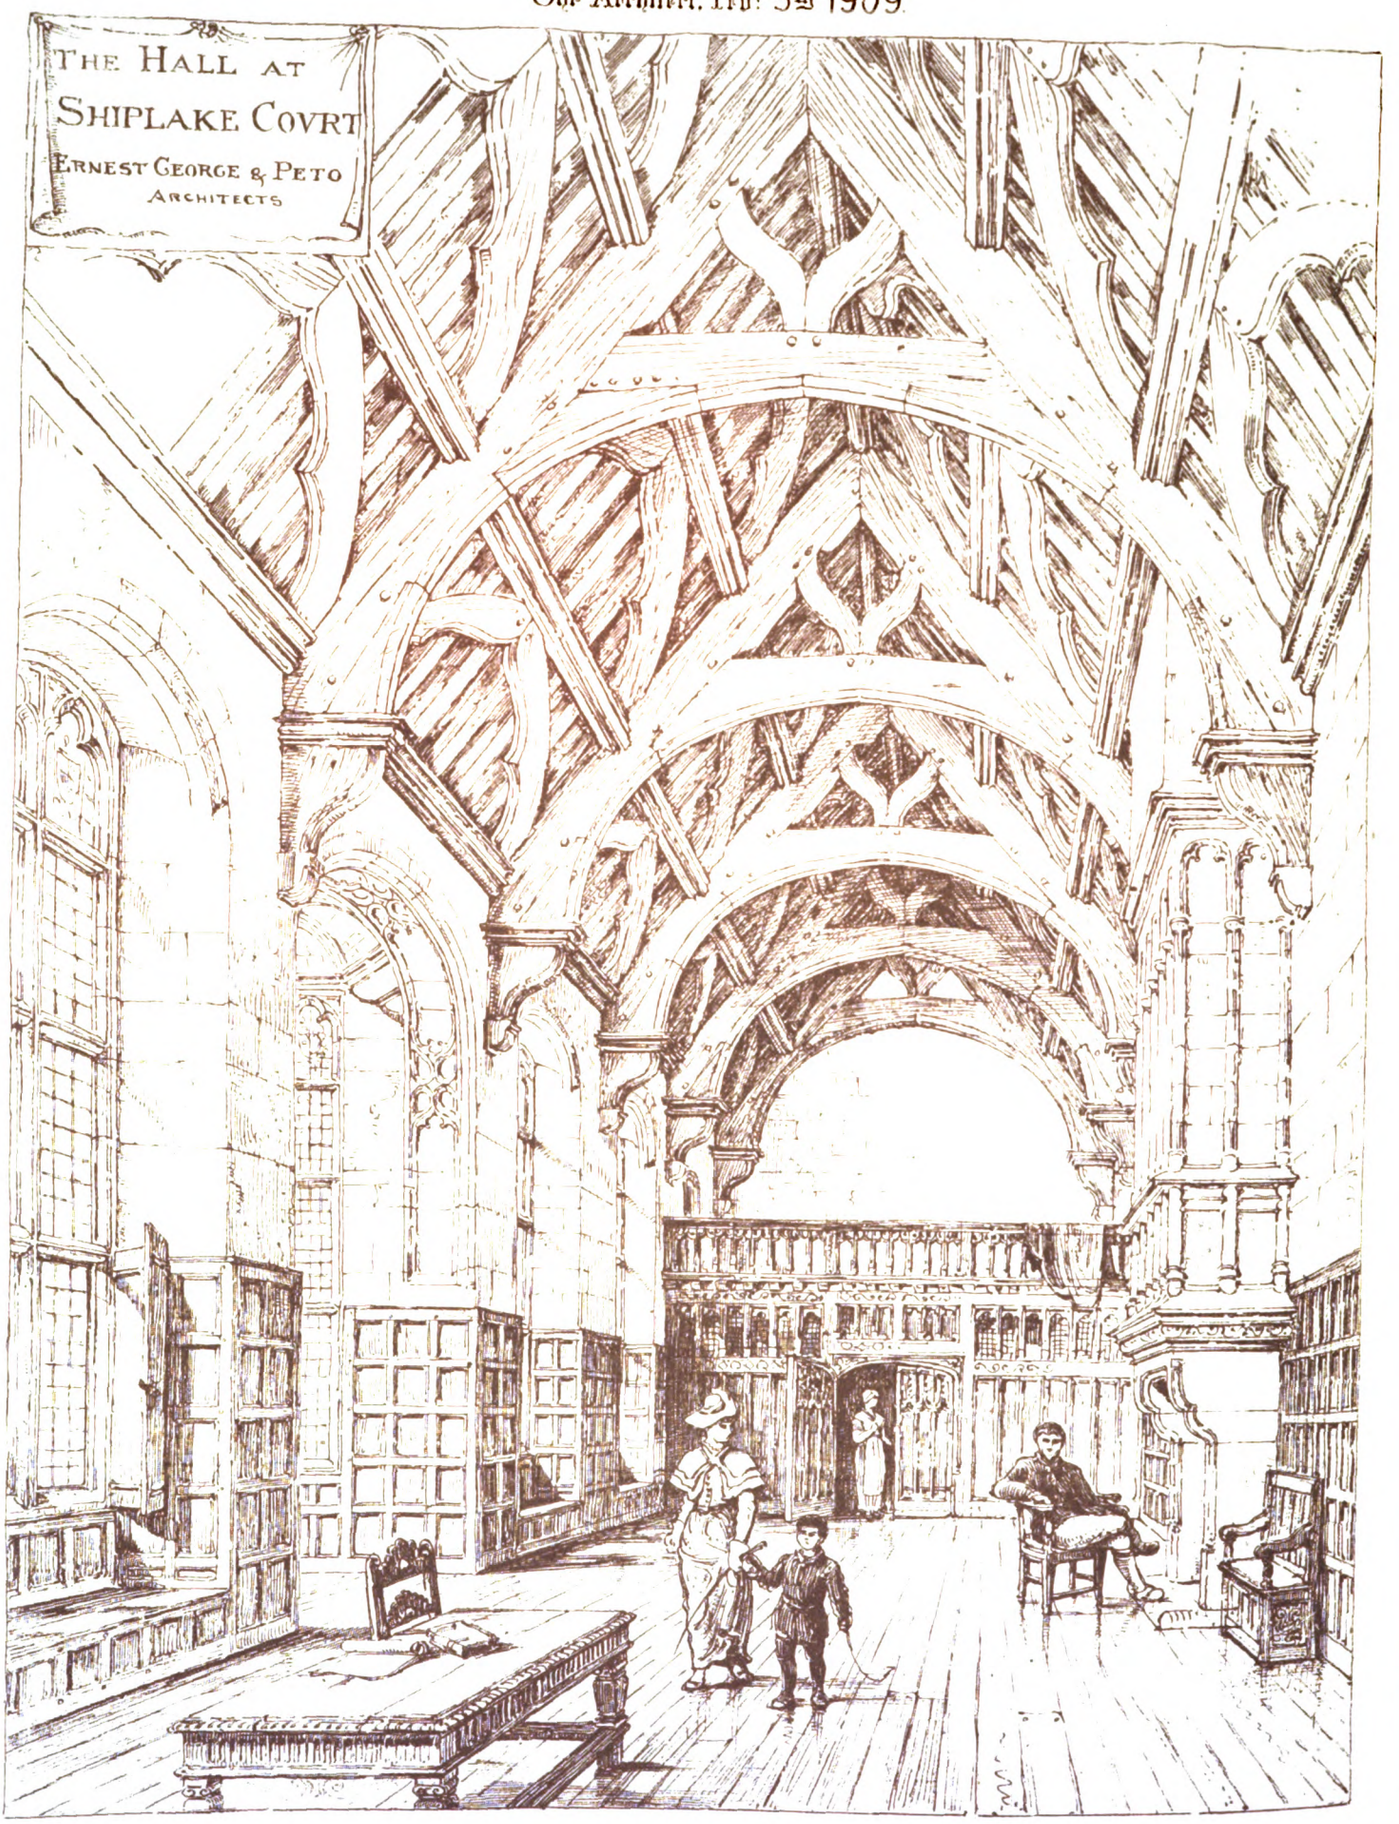
ILLUSTRATIONS.

COUNTRY MANSIONS AND HOUSES.—MR. ERNEST GEORGE.

On Monday evening last Mr. Ernest George, as President of the Royal Institute of British Architects, gave the customary address to the students. We have taken advantage of this opportunity to show some of the earlier residences which have contributed to the reputation which Mr. Ernest George has enjoyed for many years of being one of the leading representatives of his art, and especially one of the pioneers in that English domestic architecture which has won the admiration of those foreign critics who are most hostile to the architectural productions of this country.

Mr. Ernest George was born in London in 1839, and soon tasted success by winning the Royal Academy Gold Medal for Architecture at the age of twenty. After serving his articles with Mr. S. Hewitt, he commenced practice, and had as his first partner Mr. T. Vaughan; on the latter's death he was joined by Mr. Peto. When Mr. Peto retired he took Mr. A. B. Yeates into partnership. In 1896 he received the Institute Gold Medal at the hands of Mr. George Aitchison, R.A.

The earliest design which we illustrate is the large mansion, "Rousdon," Devon, built near the sea for Sir H. W. Peek, Bart., at a cost of nearly 80,000*l*. The external walls have a thickness of 3 feet, and the brick lining is 9 inches thick. Purbeck stone is used for the mullions and dressings. This house was designed while Mr. T. Vaughan was partner.



"Woolpits," Surrey, and a "House at Ascot," by Messrs. Ernest George & Peto, were shown in the Royal Academy of 1885. "Woolpits" was erected for Mr. Henry Doulton on the slopes just below Ewhurst Mill. On entering the house there is a fine panelled hall, 34 feet by 17 feet, with an oak staircase at one end. The dressings and mullions throughout the exterior are of buff terra-cotta, supplied by Messrs. Doulton. A large panelled hall, round which the principal rooms are grouped, is also a feature of the "House at Ascot." An unusual feature is the domestic chapel, 33 feet by 15 feet. The two rooms behind the verandah on the south side have each a bay window brought as far as its face, so as to prevent their being darkened.

The drawings on the opposite page to the above designs represent part of the firm's contribution to the Royal Academy in 1888. The hall of "Batsford," Gloucestershire, extends through two storeys. The view given is of the north side; bay windows are facing the south, which looks upon the park. The design shows a symmetrical Tudor house treated in a broad and dignified way, after the manner of a building of the period, and with an avoidance of fanciful features. The "Cottage at Harpenden" is more picturesque with its broken outline. The red-brick "House on Streatham Common" has the great interest of being designed for Mr. George's own occupation. From the same year's exhibit we have reproduced four small country houses at Henley, Denmark Hill, Bagshot, and Pinner.

The entrance-hall is generally a leading portion of the designs by Mr. George, and the one shown at Shiplake Court, Surrey, is 70 feet long, with an open timber roof and massive oak beams. Oak panelling is used to the height of the lower transoms around the room. At the far end is a screen and musicians' gallery. "The Poles," in Hertfordshire, is Jacobean in style. The walls are of brick, with stone mullions and transoms for the window. The dining-room, the drawing-room, and the library are so arranged that when the folding doors are opened there is a vista of 120 feet. The "Country House, Dorset," is a conspicuous exemplar of straightforward planning on a large site.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last at Conduit Street, W., Mr. Ernest George, president, in the chair.

The PRESIDENT offered the congratulations of the Institute to their old friend and able past president, Mr. John Belcher, on the recognition of his abilities by the Royal Academy, in his advancement to full membership; and to Mr. Goscombe John, hon. associate, whom the Institute appreciated as one of themselves, and who also had been honoured by that body.

Mr. ALEXANDER GRAHAM, hon. secretary, announced the decease of Mr. James Neale, who in his younger days was assistant in the office of Mr. George Edmund Street. Mr. Neale gained the Pugin Studentship in 1875, and the Institute medal for measured drawings in 1876. He was elected as Associate in 1875, and Fellow in 1890. Although not an active member of the Institute, Mr. Neale was kind enough, said the hon. secretary, to remember the Institute in his will, and had bequeathed the sum of 1,000*l.* for promoting study in architecture, or for any purpose that the Council of the Institute for the time being might deem best.

It was agreed that a letter of condolence and sympathy be sent to the relatives of the deceased, with an expression of gratitude for the beneficent donation.

A vote of thanks was accorded to Mrs. Arthur Cates for a presentation of books to the Institute library.

Royal Gold Medallist.

The PRESIDENT announced that the Council proposed to submit to His Majesty the King the name of Dr. Arthur Evans, the distinguished Cretan explorer, as recipient of the Royal Gold Medal in the current year.

Address to Students.

The PRESIDENT said:—It is my privilege to-night to address our future architects, our students, may I say my fellow-students of architecture?—for the study of the great art is not accomplished in a lifetime. The young, however, have a capacity for learning and assimilating when the old have got into ruts and have acquired prejudices that hinder the reception of new impressions.

I speak to you who have the responsibility of remodelling our cities and of making the world that is to be, I trust with a great increase to its beauty. An artist paints his picture, and if it fails it can be obliterated, or if it has meretricious cleverness it endures for a time but when found out its place need know it no more. In the art of building the case is more serious; what we build must be seen whether we will or no; it has its influence on the "man in the street." It may be a source of pleasure, or it may cause familiarity with and toleration of that which is bad.

As architects it is a first necessity that we should be builders, for the arts of building and of architecture cannot be separated. The simplest structure may attain to architecture by admirable proportion and by a wise disposition of the parts; whether decoration comes in or not is of secondary importance. The question of style is a minor matter, for the artist's hand will be evident in the work, whatever the treatment he affects or the vogue of his time.

The education of the architect has been taken seriously of late, and his facilities for study are greater than ever before. I will not discuss the details of the training of which you have the advantage, but with it all I would say that what you do earnestly for yourselves is worth more than all that your able professors can do for you. They will endeavour to put you on the right path and to inculcate the principles, but it remains for you to give them practical application.

Much has been said about technical training, with the study and handling of material; and it would be all to the advantage of the architect that he should be a good joiner, mason, or worker in metal. When drawing a moulding he should have stone, oak, or plaster in his mind. He has so many good books of "Examples" now that he is apt to become a paper architect, losing familiarity and touch with the realities of building. Modelling is a useful accomplishment, and should be part of the training: it aids in the expression of ideas where the pencil often fails. The architect has, however, in the few years that can be given to preparation, so much to acquire that he can hardly spare time to grow efficient in the various crafts. Some have found practical knowledge by a term in a builder's yard, and I think I am right in saying that this was the early training of Richard Bentley, whose architecture gives evidence of his knowledge as a masterly constructor. Still, a boy must leave school prematurely and in a half-baked condition if he seeks apprenticeship to the crafts, and it is difficult to say at what age general education should give place to specialising.

The greatest architect that England has produced was known only as a man of science and a professor of astronomy until the age of thirty, when the resources of his great mind were turned to the art of building, at which he presently showed himself an accomplished artist. Notwithstanding this late start in life, Dr. Christopher Wren was allotted sixty years in which to build our cathedral, rebuild our city, and raise the many monuments that he has left to us as a precious heritage.

With the rudiments of scheming and planning, freehand drawing must be cultivated; and working from the cast and from the figure is perhaps the best training for the eye and for the hand, while it teaches a sense of proportion.

No work is more profitable than the measuring and careful study of existing buildings, making choice of fine specimens, and I am pleased to state that suggestions and directions for the guidance of students will shortly be published by the Institute in pamphlet form, giving a list of examples throughout the country that are considered most useful for study, also specifying those which will be valued as an addition to our architectural records. Those of you who go out with our scholarships, instead of sketching in a desultory way, will be advised to study seriously some building of distinct architectural merit, and it is intended that the result shall be published in some permanent form. It should add to the student's zeal and interest if he feels that he is thus contributing to the world's store of knowledge. See what details and mouldings give the strength and quality that you admire; note their size and projection, but, doing this, show also their place on the building. Note-books are sometimes filled with interesting doorways and windows, without a record of their relation to one another or to the wall-spaces that give them value. Study critically the buildings that impress you as fine; find out where and why they are good. It is a curious thing that criticism has come to mean exposing the faults; that is the easier and the more telling form, but it is a bad spirit to adopt. I have often been shocked at the flippant criticism by mediocre men of fine work of which they would themselves be quite incapable. The faults they see probably exist, but the quality and essence of the building are not in those imperfections. Make mental notes, if you will, of ways that you feel should be avoided, but seek the good first; it is the more profitable study.

As architects you will often be asked what you think of this man or that; perhaps you do not feel the architect in question to be one of our great lights. Let me beg of you to stretch a point and say all that is generous, though perhaps of a rival. It is unsportsmanlike to give away a professional brother or to damn him with faint praise. His reputation is his stock-in-trade. Let us among ourselves use all frankness: it is helpful to have our weaknesses pointed out if we are wise enough to profit thereby.

We have had so much of draughtsmanship, sometimes with very little behind it, that great facility has got rather into disrepute. The mind is sometimes better employed when the fingers are not too nimble; nevertheless the power to draw and to express your ideas with the pencil is one of the happiest endowments of the architect, and should be assiduously cultivated. There should be a careful avoidance of tricky methods, for we have seen drawings so pretty in themselves that the absence of good design is overlooked; the drawing is looked upon as an end, instead of being a simple medium or a diagram of the proposed building.

It is curious to look back on the fashions that have prevailed in my own time. When I was a pupil most perspectives were coloured, and there was a small income for many who were adepts at a skilful throwing-on of colour; then George Street, Norman Shaw and Eden Nesfield showed how much of the real qualities of a building could be expressed by line. One incident of the time was the discovery that one of these masters used a notched straight-edge, thereby admirably rendering the texture of roofs. I confess to having sacrificed a T-square myself in that cause. Light and shade, whether with line or the brush, are desirable to explain fairly the shape of a building. There was a pretty and telling way of leaving roofs and spaces white, as if under snow, with strong black touches here and there, the result being effective but not a fair rendering of the future structure. In one of my wanderings I met a nice young man who proposed making a study of art; I am not sure that he could draw, but he was interested in some blue and red chalk

Digitized by Google

with which he touched in passages of his work: he found this treatment in the studies of the Old Masters to which he desired his sketches should approximate. If you have the power of drawing, it matters very little by what vehicle your thoughts are told, and all tricks are a hindrance to truthful expression. A method that obtained lately among the younger students was that of running the lines out beyond their natural limit, thus giving to a cornice or a stringcourse an unreal weight and importance instead of defining its contour. This may look brisk and sketchy, but a student's time is not very valuable, and a further half hour would be well spent in making the drawing correctly explain its parts. Do not be afraid of being methodical and exact, rather than sketchy. Nothing is more offensive than "sketchy" passages from a hand without the artist's mind, impressionism which is only scribble.

Fortunately Bohemianism has ceased to be a distinguishing mark of the student, for I can remember when nearly every Academy student wore long bushy hair; I am not sure whether I did so myself; I could have done so then. I see among you now men of fashion, with the greatest correctness of costume. Still I would say to the serious student do not be so beautifully dressed that you cannot carry a sketch-book or a two-foot rule in your pocket. You should be so far ready for work that the eight o'clock dinner, for which you must dress, is not always imperative. Michel Angelo, during a fifteen hours' spell of work, was content to munch bread; he slept little, finding that sleep made his head ache. He said that though he had made himself rich by his work he had lived always as a poor man. We may not all, like this giant, bring the mind to dominate the body, but I am sure that simplicity of life is to be aimed at by the true artist. You are fortunate in having your great interest in life; you have no need of the expensive pleasures or distractions that save the gilded youth from being bored. Much good work has been done in a garret, and I believe that the admirably appointed young man finds it less easy to throw his soul into his work than does one to whom art is the companion and solace. I would not have the artist a drudge; variety, good company and recreation are necessary if the work is to be a pleasure. It is essential also to move among men and to make good friends, for it is no use being a good architect if you have not a client to bring the work Accept week-end invitations, and, if you can, interest your host in a clever suggestion for altering and beautifying his place.

I hope with most of you that your art is sufficiently interesting to be the purpose of a holiday, whether in getting away on a Saturday or taking ten days in Brittany. You will be told that you want relaxation from work—golf, perhaps, or a lounge in a house-boat. From my own experience I would say there is more change of thought and of interest for the mind in seeing and assimilating fine things, living out of doors all day, sketching and measuring with a change of scene, of climate, diet and language. Our own beautiful country will supply matter enough for study, but crossing the Channel I have found to make a more complete break with the life of the office.

I suppose, without question, in the period that my memory covers, Mr. Norman Shaw has been the most followed, I might say the most copied, through the successive phases of his work; for the strongest men will always have a large following of those who imitate their manner. I value to this day the several books I managed to buy out of my youthful allowance, and among these are the sketches of Shaw and Nesfield. In their exposition of the architecture of France the examples chosen are all Mediæval; later work was not accounted of in those days.

I remember, in my own early visits to France and Spain, regarding the Renaissance screens in the churches as wicked innovations, although fascinated by them against my judgment. A château of Louis Douze or of François Premier was a rich find, while a work by Mansard or Vanbrugh we counted ponderous and dull. By common consent we now seek the more formal examples of buildings, and what was once dull we find dignified and restrained; while some will tell us that the quaintly picturesque, our first love, is hardly to be taken seriously as architecture. Unquestionably the student should study the purer classical works, rather than the picturesque Jacobean or Dutch versions, or perversions, of the same. There was an earnest attempt to gather up the traditions that were snapped in Tudor times; now the prevailing desire is to revive the later methods that had become traditional here until the advent of chaos; and in this last is our best chance of arriving at a happy unity of aim.

We may be disturbed again by waves of fashion, for no arbitrary law exists in matters of taste. There are Eastern races with a really fine sense of beauty, as shown in their splendid arrangements of colour and in their gorgeous stuffs; yet, among these, a lady can make no claim to beauty unless she is fat. Our standard differs from theirs and our taste is more catholic; yet it is difficult even for the most cultivated to keep an open mind for the appreciation of what is fine if it is not in vogue.

It is unnecessary to insist on the advantage of wide knowledge and of general culture. Avoiding the purely archæological spirit, history is perhaps the most interesting subject and the most sympathetic with our central thought or study. The world's history is written in its architecture, and it is a part of our schooling to follow the developments and to trace the growth of the various methods or styles, noting the influence of one country or people upon another. Our interest is less in the names or in the characters and peculiarities of kings than in the *work* that was accomplished in given periods and in the great masters of the arts that such periods produced. If a name or a date is mentioned, we can localise it by calling up the Byzantine, Mediæval, or Renaissance environment of the subject; it makes the past very real to us. The knowledge of foreign tongues is an invaluable aid to the architect. Through my own indolence in acquiring or in keeping up my knowledge of these, many precious books are closed to me; while in travelling one is often surrounded by people with whom the exchange of ideas and even the gentle amenities of life are difficult.

I have spoken of the study of fine buildings and of the use and misuse of the note-book, which we like to bring home full of pretty things. In our search for the latter we may possibly miss what is noblest in architecture. The sublime is not readily transferred to the sketch-book; it is no use making picturesque jottings of the Parthenon or the Pantheon. Those who have great facility with the pencil find less effort in the use of the fingers than in the exercise of the mind.

Drawing, to which I give a high place, may at any time become a snare, being made a substitute for contemplation and analytical thought, the seeking out of a reason for the forms we see, learning whether they were determined by the necessities of construction or were evolved as a part of a beautiful composition.

My fellow-workers may expect of me some remarks about water-colour sketching, which has always been my happiest recreation. Under favourable conditions of climate, with a sympathetic friend, a day spent with the brush in a spot selected for its beauty is as good a time as I can well imagine. The travelling student may wisely turn to brushwork for relaxation from the more exacting forms of study. We architects do not sufficiently consider the value of colour. We think of form, and perhaps light and shadow; too often conceiving a scheme in elevation only. One who paints must consider buildings in perspective, also taking account of their colour and their relation to surroundings. Yet of the student who is good enough to obtain an architectural prize from the Royal Academy or from our Royal Institute I would beg that he stick to his trade. Let him not, because he finds that he can paint pleasantly, throw architecture aside, however great the difficulties to be faced, before palaces or cathedrals are entrusted to him.

I have spoken of drawing and painting: what shall one say of photography? The art, or shall we say the science, brings to the eye all that is finest from all parts of the world—Indian temples, Venetian palaces, Eastern minarets, the sculptured doorways of great cathedrals, and these often taken with judicious lighting. By photographs or photo-prints memories of the world-treasures are brought to the armchair. As it affects the student this is a doubtful advantage; that which he attains without effort is hardly a possession; he had better worry himself for hours making an indifferent drawing than secure the best of photographs or of book illustrations of his subject.

In the last few years choice books have been added to our architectural libraries: the subjects, admirably selected by men of judgment, especially setting forth the beautiful houses throughout our own country. These we value while urging the student not to misuse them or make them an excuse for shirking the prosaic work of measurement and personal study; he is apt to be distracted by the quantity of material ready to hand and the many inventions presented to him, hardly leaving him the chance of originating. There is also the handy "kodak," by means of which he could snapshot that which would take a day to draw. We accept these things with our advanced civilisation, while we question if

Digitized by Google

art is advanced by photography any more than music by the marvellous gramophone.

We have discussed the methods of study; how can the acquired knowledge best be applied or tested? I think there is no more useful exercise than to enter heartily into these competitions for medals and prizes. Doing so you are for the time being the architect to a palace or some monumental work with grandeur and scale to which you may perhaps never have the chance of building; but whether the prize falls to you or another, the benefit of the effort remains yours. Again, a little later, you begin for yourselves, and confiding relations entrust you with an additional wing, stables, or a motor-house. Your time is not filled up as it should be, and it is worth your while to take your two-hundredth chance in competition for the exercise of your imagination and powers of design; it is valuable training. The Open Competition is a quite unreasonable venture if looked upon in any other light than this; a multitude doing the work for which one only is commissioned.

This evening is the first occasion on which the prize drawings have been with us during the address to students and the review of their works; a discriminating friend will presently discuss the latter critically and in detail. I will only say that the competitive drawings reach a higher level this year. Some of those that escape mention might have carried off a prize in some previous competitions. There is not only good draughtsmanship, but in some cases evidence of design and composition, with an effort towards the "grand manner."

As we have said, there are fashions in our art and they influence the student. It is interesting to note that whatever the subject set, whether the "landing stage," the "corridor of shops," or the "pavilion," a dome of noble span is a leading element in the designs. Perhaps domes may become features in the architecture of the future; during my own career I have not been allowed the opportunity of raising a dome.

We have discussed methods of study and modes of working and drawing, but we must keep well in mind that these are but preliminary steps and stages. Looking on our great cathedrals and noble monuments of the past, we must remember how little they owe to draughtsmanship. No beautiful drawings, such as we see to-night, preceded the building of Westminster Abbey. The master mason chalked out indications of what was to be, and such lines were followed with more or less accuracy, slight inequalities giving a charm to the whole. It is pleasant to come upon elevations or studies for buildings by the great masters, but these, as drawings, would not pass muster with those before us to-night. We judge the embryo architect by his drawings, and it is generally a fair test of his worth. Yet we would remind him that to use art and science in building is his vocation, and there is none higher.

A poet has said—

> To build! to build!
> That is the noblest art of all the arts.
> Painting and sculpture are but images,
> Are merely shadows cast by outward things
> On stone or canvas, having in themselves
> No separate existence. Architecture
> Existing in itself, and not in seeming
> A something it is not, surpasses them
> As substance shadow.

Mr. PAUL WATERHOUSE read a criticism of work submitted for the Institute prizes and studentships.

Mr. J. J. BURNET proposed a vote of thanks to the President for his address and to Mr. Waterhouse for the admirable criticism on the architectural drawings. He advised students not to forget the seriousness of architecture in the cultivation of sketching and drawing, and to realise that the architect in practice must subjugate himself to the needs of the client.

Mr. W. J. LOCKE seconded the motion. Architectural students, he said, had an immense advantage over those who followed the art of letters, insomuch as the youthful efforts of the architect were encouraged by friendly criticism, whereas the student in literature received no such aid.

The PRESIDENT then delivered the prizes and studentships, the full list of which appeared in *The Architect* of January 22.

The Royal Society of Antiquaries of Ireland will hold their next meeting at Clonmel in the first week of July.

Mr. J. W. F. Phillipson, architect, Newcastle-on-Tyne, has been successful in a competition for new school premises (Primitive Methodist) at Consett, co. Durham.

AN AMERICAN BUREAU OF FINE ARTS.

THE American Institute of Architects have received the following report from their committee on the Bureau of Fine Arts:—

Gentlemen,—The committee on the Bureau of Fine Arts have the honour to report as follows:—

This subject is presented to the convention, not only as an abstract æsthetic question, but as a grave, practical problem, affecting great interests of the public generally and the economic administration of the National Government. The committee, after mature consideration, recommends that immediate action be taken towards the establishment of a Bureau of the Fine Arts, as a part of the governmental machinery, believing that it is necessary to the public welfare.

This definite and positive recommendation is the result of an investigation and examination of the records of the different departments, through which the following facts have been ascertained.

Since the foundation of the Government, more than $500,000,000 of public money has been expended for buildings and other works of art, which should have been under the control of a Bureau of Art.

In addition to this amount, large sums have been spent for parks, bridges, aqueducts, harbour improvements, designs for coins, stamps, bonds and bills, the value of which would have been greatly increased had they received intelligent artistic consideration.

About 90 per cent. of this total amount has been spent during the last twenty years. In the immediate future there will be spent the sum of $45,000,000, for which appropriations have been made.

Under existing conditions, there are many kinds of machinery for controlling these expenditures. Usually each act of Congress appropriating money for artistic work specifies the method of procedure, and designates the person or persons in whom the authority is vested. As a result, it is sometimes the President, a member of the Cabinet, a committee of the Senate or House, or a department or bureau; sometimes an army engineer, the superintendent of the Capitol, a committee of the Grand Army of the Republic, a special or private commission or a private individual, who controls and regulates the choice of the artist and the expenditure of the public money, and who acts not infrequently as artistic arbiter. In each case the arbiter regards the enterprise from his own point of view, without respect to its relation to the whole æsthetic question, and the result is, generally, waste of public money and always artistic chaos.

Your committee submits that the expenditure of this vast sum of money, without the supervision of a well-organised and competent authority, is unbusinesslike, improvident and not economic government. The fact that the present appropriations show that the ratio of expenditures for these purposes is increasing annually, seems to your committee to indicate that the necessity for action is urgent.

During the past, as many as fifteen bills have been introduced in Congress to remedy these evils. A synopsis of these bills has been compiled for the Public Art League of the United States.

The general character of the bills is best described in the report, as follows:—

"After an examination of all the bills which have been presented to Congress in connection with this subject, the committee feel that their effectiveness, if they had become laws, would have been marred for the following reasons.

"Such bills were introduced with the idea of ameliorating evils which existed in single departments or in single cases, one covering paintings and statuary for a single building; one the question simply of paintings; several bearing upon the buildings of the supervising architect's office.

"The fundamental error in all attempts at legislation has been in confining the law to one branch of art, or to isolated buildings. As buildings and their decorations of painting and sculpture, and the landscape, including monuments and fountains, are so intimately associated with each other and the effect of any one so easily enhanced or marred by the other, they should all be under the direction of one guiding body. The only way to obtain a harmonious whole is to have them all in the hands of one department. The lack of harmony between different buildings in Washington, the total lack of unity in the selection of their sites, and the still more notable deficiencies in the character, location, and fitness of statues and monuments, are all due to the separate committees, individuals and departments which have had charge of such matters for the Government."

Digitized by Google

The first step toward a solution must be to recognise that the artistic problem is a single one. That the object sought is the product of a great totality. That the selection of sites, the general distribution as well as the design and execution of architectural work, monuments, landscape work, sculpture, painting, mural decorations, bridges, parks, and their accompaniments, are all parts of a coherent whole, and must be subject to one single authority, invested with such dignity as to command respect for its decrees, and that this authority must be guided by the most enlightened advice which the artistic professions can furnish.

Your committee therefore recommends as a remedy for the existing evils the establishment of a permanent Bureau of Fine Arts, the essential element of which shall be a Superior Council composed of a number of men of known and recognised eminence in the profession of the arts.

Your committee is guided in this action by the example of the older nations, notably France, whose logical treatment of this important question has placed her people at the head of the civilised world in all matters pertaining to the arts.

In order that the Institute may have at hand precise information as to what has been done in this matter in foreign countries, your committee has obtained from official sources a synopsis of the organisation of the French, German and Italian Ministries of Fine Arts.

In further support of its recommendation, your committee quotes the following resolution, which was passed after a thorough discussion at the International Congress of Architects at Vienna in July of last year, 1908, the subject of governmental direction of art having been designated as one of the four subjects for consideration by the Congress:—

"Resolved:—That every Government be urgently requested to establish a Ministry of Fine Arts or at least a section which shall deal with subjects relating to the arts. To such a ministry or section shall be attached artists of established reputation. Since architecture can be considered the leading art, architects shall be in a majority. The work of this ministry or of this section shall be the advancement and encouragement of the fine arts in all their branches."

This resolution has been endorsed by the principal artistic bodies of eighteen nations in Europe.

Your committee has judged best to place before you the economic and business aspect of this question first because from its point of view the necessity for immediate action is urgent. Viewed from the economic standpoint alone, the pecuniary benefit of a well-organised and regular system for the expenditure of great sums of public money must be sufficiently obvious.

It is obvious that existing value is never destroyed, but that, on the contrary, commercial values are always enhanced and new values created by artistic treatment.

To the great mass of cultivated and intelligent citizens of our country who recognise the irresistible force of abstract ideals, and who appreciate the lessons of history, there is a vastly more cogent reason for altering existing conditions.

It is that the expenditure of this vast sum of money signifies that we are establishing, at a rate never before exceeded, lasting monuments to our civilisation, and that, without proper management, these monuments will not represent and typify the state of cultivation which our people have achieved. The works of art of a nation are the records by which it is judged by posterity.

A nation's literature, its coins, its buildings, statues, paintings, bridges, roads and tombs are the undying testimonials of the character and intellect of its people, and the permanent record of their achievements.

The common desire of every race in every period of their history to preserve and guard artistic treasures evidences the instinct for beauty and the aspiration for immortality. The permanency of works of art is a sufficient reason for extraordinary care in their design and execution. When such works are undertaken by a Government, a high standard of excellence becomes a civic obligation.

It is the duty of the State, itself a product of the cultural needs of humanity, to recognise and foster the culture of the arts as the most powerful agency for uplifting and elevating the ethical standard of the people.

It is our duty to ourselves, to our forefathers, and to posterity to see that the monuments which we are now erecting, these records which our Government is now making, should be worthy representations of the true state of our social conditions and an evidence of the taste and cultivation of our time.

To those who recognise these facts should be entrusted the guidance of legislation concerning our monuments. It is their duty to demand that the expenditure of these enormous sums of public money should be made with all the wisdom, foresight and intelligence of which we, as a community, are capable.

As to the form of a Bill to present to Congress, your committee deems it advisable to wait the result of the discussion of this report, but submits the following suggestions:—

(*a*) That the Bill shall provide for the organisation of a bureau which shall have control.

(*b*) That there shall be a Superior Council, composed of eminent architects, sculptors, painters and other artists and laymen distinguished for their interest in and knowledge of the fine arts.

(*c*) That the members of the Council shall be appointed by the President by and with the advice of the Senate.

(*d*) That the recommendations of the Council shall be binding upon the chief of the bureau.

(*e*) That the chief of the bureau shall be the representative of the Government in all transactions involving the employment of architects, painters, sculptors and other artists for public works, and shall decide, with the concurrence of the Superior Council, upon the methods of choosing and the choice of artists or public works of art.

(*f*) That all public works (of a character to be described) shall be supervised by the Bureau of Fine Arts, and that the decision of the Superior Council in all such matters shall be final and binding upon all departments.

It is recommended by your committee that the following subjects should be included in the authority of the Bureau of Fine Arts:—

1. Architecture, painting, sculpture, park work and engraving.

2. Educational matters pertaining to the fine arts and the dissemination of useful knowledge among schools, colleges and universities pertaining thereto.

3. Administration of the National Gallery of the Fine Arts.

4. A system of national museums in different cities, and that a system of circulating works of art throughout the country be established.

In conclusion, your committee repeats from its report of last year:—

"The intention of establishing a Bureau of the Fine Arts is not to develop a national style of architecture or definite styles of painting or sculpture, but to invest the whole subject of the fine arts with appropriate dignity, to encourage the establishment of proper schools, to stimulate the universities in this much neglected branch, and to educate the people.

"In other words, the purpose of a Bureau of the Fine Arts would be to propagate the truth that art is not an effeminate luxury, but that it is the manifestation of that great vital force, the imagination, which is the original impulse behind all human progress; and to, furthermore, teach the people of the United States that if there is one thing above all others which is absolutely and universally democratic, typically and thoroughly American, and essentially in accordance with the whole spirit of the constitution, it is the inalienable right of all the people by inheritance to possess and preserve the works of genius of the human race, and to participate equally in the inestimable advantages and benefits of the study of the fine arts."

REINFORCED CONCRETE.*

(*Concluded from last week.*)

I NOW come to the consideration of the general structural lines of erections in these materials. In beginning a design for a reinforced concrete structure, the first thing the designer feels is the absolute lack of precedent. In dealing with structures of brick or stone, or even steel, there are by this time more or less recognised ways of solving every ordinary problem of design. If the designer be possessed of great originality, and can deviate from the hackneyed methods in a direction which others feel to be an improvement, then he has produced that which is not only interesting and pleasing, but he has advanced the art of design. But if he find himself unable to improve on the usual solution of the problem, then he is not blamed for adopting it; but he has failed to produce anything possessing special interest.

In designing reinforced concrete, however, no tradition or precedent exists; and if the designer should be unable to evolve from his own brain a form of structure which shall

* A paper by Mr. T. H. Markham, read at the last meeting of the Architectural Association.

Digitized by Google

be at once sound as to constructive principles, suitable to the material, beautiful as to form and appearance, and withal practicable from a commercial point of view, then he fails to produce a satisfactory reinforced concrete building. This lack of precedent becomes a very real difficulty in a structure in which the utilitarian requirements give considerable latitude for the possible variations of form. One asks oneself, "How shall I begin? How is a thing of this sort usually done?" Then, to save oneself trouble, one is apt to fall into one of two errors, or possibly both, and to treat the structure as a steel structure would be treated, or else as a stone building.

Here I would just refer to the use of concrete as a structural material in ancient times. You will all remember the Roman use of concrete in large masses, though with a kind of reinforcement in the form of brick arches and lacing courses. Their concrete owed much of its strength and durability to the employment of a light volcanic earth, known as pozzolana, which formed with the lime a very strong hydraulic mortar. The chief uses to which concrete was then put were to form floors, or to form large vaults and domes with brick arched ribs and brick lacing courses, or to form walls with, generally, a facing of brick or stone. Since Roman times builders have not had the advantage of such an excellent material as pozzolana, and concrete almost dropped into disuse. Something similar was probably used for foundations in the form of very coarse and random rubble work, and as a covering to vaults in the mediæval buildings, but it is not anywhere evident as a part of the designed structure.

As to structural lines, the Roman use of concrete affords us no precedent for designing in reinforced concrete, because their use of the material was in *enormous* masses, and could only be where the principal stresses were compressive. Their concrete domes are said to have had no thrust but act merely as inverted saucers. Where they supported nothing but their own weight, the thrust might have been negligible; but it seems to me that there must have been a sort of internal arch action among the particles of the mass, and the thrust so produced, if not transmitted to the walls, must have been counteracted by the tensile strength of the concrete. If a superimposed load were placed on the dome, I think this thrust would surely have become more than the tensile resistance of the concrete could withstand, and unless some outside aid were forthcoming the whole would collapse. However, as I have already stated, we do not rely on the tensile resistance of concrete in any way. Wherever tensile stress exists, steel must be introduced. Moreover, another essential difference is that, whereas a Roman concrete wall was of very considerable and practically uniform thickness, taking stresses all along, in reinforced concrete no such arrangement is permissible. A wall consists of a framework of stanchions and beams, which take all the stresses, and the remainder of the wall is formed of mere screen panels of very little thickness. This is true of steel-frame buildings also, and it is this principle which is the only one that will affect the structural lines of architectural buildings. By architectural buildings I mean those forms of structures usually designed by architects as distinct from engineering structures, such as bridges, large roofs, water towers, &c. I think this framework and panel treatment should make itself very evident; and it would seem quite suitable to build the panels afterwards in some other material as brick, stone, block concrete, or terra-cotta, each panel being carried by the beam below it. The vertical members will, as a rule, be emphasised, as they are more important, becoming larger and stronger towards the bottom, because there they carry the whole load of the wall and their proportion of the floor loads, whereas the beams all do practically the same amount of work—i.e. carry the panel over, and a proportion of the floor—and are therefore [illegible] However, in some cases the horizontal members are emphasised, and the vertical members kept subservient. In buildings of the warehouse and factory class the windows are often made to take up the whole of the panel space.

I have alluded to the tendency to treat a reinforced concrete building in the same way as a steel structure as an error. I admit a certain reasonableness in such a course, on account of the fact that both methods of construction are subjected to exactly the same dynamic laws. We have already classed them together as being identical in their effect on the lines of architectural structures; but in engineering works, so-called, they will be somewhat different in their characteristic forms. Perhaps it may be thought somewhat out of place for me to address you on the subject of engineering, but I see no sufficient reason for the distinction between engineering and architecture. In old times bridges, towers, viaducts and such like erections were designed and carried out by the same men who designed public buildings, and probably private houses as well; so that I shall presume we still maintain some sort of intelligent interest in such work, though we may never be called upon to undertake it.

There will, I think, be much more scope for the use of reinforced concrete, and opportunity to evolve a suitable style of design in such buildings as bridges, large roofs, as over swimming baths, &c., towers for various purposes, lighthouses, tanks and reservoirs, to say nothing of all kinds of foundation work, than there will be in architectural buildings; and it is such I shall have in mind in speaking of the difference between steel and reinforced concrete.

In these structures reinforced concrete is likely to find favour, because it does not need the periodic painting necessary to preserve a steel structure from corrosion. In most, if not all, works of this kind, economy of cost is an important consideration; and in steelwork the cost varies approximately as the amount of material employed. Not so with reinforced concrete. In a plain and simple building of reinforced concrete about 30 per cent. of the total cost is expended on centreing and falsework alone, which all disappears when the structure is completed. Again, the metal costs a great deal more than the concrete, bulk for bulk, so that it may quite well happen that a design which uses a considerably larger quantity of material than the minimum possible may be of much less expense in execution, because it is of such a simple character, that a great saving of falsework is effected, or members are so skilfully arranged, both as to position and their internal composition, that the concrete is made to do as much work as possible, and the minimum quantity of metal is used. Therefore I would say, first and foremost, let parts be simple and large, rather than intricate and small.

In steel structures a certain all-overishness is often noticeable, arising from the use of small members in a sort of truss form of spider's web appearance; but in reinforced concrete it is better, if possible, to use larger main members and confine the connecting trusswork to certain parts. This gives a pleasing appearance from the fact that the more intricate parts are concentrated and the main members emphasised. This is, of course, not always possible, but can sometimes be contrived with a little thought. The volume of material is increased, but a saving may be effected on the falsework.

(The ethics of imitating stonework I speak of under my third heading.) Moreover, a great saving is effected if parts are repeated so that the same falsework may be used more than once; only it is not much good repeating any particular form or feature in another part of the structure much on the same level, because the falsework will be wanted in both places at the same time. Where repetition occurs, it should, if possible, be arranged so that the falsework will be finished with in one place before it is wanted at another. I am not advocating the repetition of parts *ad nauseam* by any means, but it is quite possible often for the same form to be repeated two or three times with very slight variation, not necessitating much adjustment of the falsework. In this connection I would mention that I have been told that it is not found economical to use the same wooden centreing more than three or four times. After that it becomes warped and surface-hardened, and the expense of correcting the defects is as great as forming new.

I need scarcely speak of the advisability of concentrating ornament and using it on the parts which have no great structural function to perform, so as to leave the main structural members simple and apparent as to their importance. At any rate, ornament, if applied to structural members, should be such as will not in any wise render the member apparently less fit to perform its function.

This brings me to my third and last division—decorative design and surface finish. In this part of our subject we may learn a lesson from the Roman builders, in that the surface treatment of concrete may be the same, whether it be used as mass concrete or reinforced. Roman concrete walls were finished in three different ways:—

1. Opus incertum, where the wall is faced with irregular pointed pieces of stone placed with the point inwards.

2. Opus reticulatum, which consisted of similar pieces of stone to those of the opus incertum, only the faces were square and regular, and the surface presented a sort of network appearance.

3. The walls were faced with thin triangular bricks laid breaking joint.

Digitized by Google

Yet another method was to apply marble slabs, fixed to the wall by metal cramps. This method was also applied to brick and stone walls.

Vaults and domes often had coffers cut into their surface and the whole covered with a fine cæmentum marmoreum.

All these methods are of course still possible, and to them may be added mosaic and tiling.

As to modern methods. A very favourite way is to render the surface to resemble stone construction, and in some cases V-shaped strips are nailed to the falsework to form depressions in the finished concrete, similar to V sunk-jointed masonry, and the surface picked over to leave the flat surfaces rough. The attempt to imitate stonework so frequently adopted in buildings of reinforced concrete can scarcely be described as "building in truth," and therefore I must condemn it.

A certain similarity of appearance there will be of necessity between buildings of reinforced concrete and those of stone. I am not urging that this similarity, where it is natural, should be concealed, but I am deprecating any attempt at making the two alike. Two essential differences which I think should certainly have their effect on the types of design suited to each material are:—Firstly, that whereas stone walls are more or less of even thickness, supporting weight all along, walls of reinforced concrete are composed of stanchions and beams with screens, as before explained. Secondly, many features in stonework design are the outcome of the necessity for using this material in separate blocks. Reinforced concrete is a monolithic material. There are no joints; and I think all that, which in stonework design is the outcome of the necessity for separate blocks with joints, should be eliminated. For instance, a stone column has base shaft and capital, and the capital especially is distinctly a different piece of stone from that forming the shaft or architrave, and is treated as such. If a reinforced concrete support receives an enriched treatment at its upper end I think the ornament should run on to the beam above and possibly connect up with the base of the stanchion over. A reinforced concrete support in the form of a Corinthian column would be most inappropriate, though I would not object to a reinforced concrete beam being moulded as a Classic architrave. I think my meaning will be clear.

Another method, which is rather cutting the gordian knot than untying it, is to do all the structural and internal work in reinforced concrete and to form the front facing screen in stone or brick, built up independently of the rest of the structure and attached to it at the floor levels by allowing some of the floor reinforcements to project and be built into the masonry screen. This method is being employed at the road frontage to the new Post Office building. When this is done care must be taken that the slight settlement of the reinforced concrete structural part, which is bound to take place when loading has been applied, does not throw a certain amount of stress on to the masonry screen and so cause it to bulge.

It seldom happens that the concrete can be left without further treatment after the removal of the centreing or falsework in cases where the appearance has to be considered at all. Sometimes moulds are lined with zinc, sheet iron or plaster of Paris and oiled to prevent adhesion, and a coat of mortar to give a smooth surface is applied to the inside of the mould first, and then the concrete and reinforcement put in afterwards, but not forced so as to press through the mortar and appear on the surface when the falsework is removed.

In some large office buildings erected by the Turner Construction Company of New York the only treatment, applied after the removal of the wood falsework, was to put on a coat of cement and white sand with a brush. Another method they have tried is to apply a coat of oil paint, mixed with sand. In cases where very little work is done after the removal of the falsework some special precautions have to be taken to remove the unsightly variation in texture which is visible wherever a break in the laying occurred.

A certain percentage of colouring matter may be added to the cement if desired; the amount, say Messrs. Marsh & Dunn in their admirable book on reinforced concrete, should not exceed 10 per cent. per volume and should be less if possible. Of course care must be taken to ensure that no colouring is used which will have a chemical action on any of the materials used or be easily affected by the acids and other substances in the atmosphere.

It would seem that in treating the surface of reinforced concrete buildings all decoration should be comparatively flat, and if any ornamental features are added of considerable projection they must be reinforced and form part of the structure. The surface coating should be as thin as possible.

I would suggest that a suitable form of decoration would be a kind of sgraffito work done in this manner, the mould to be formed of plaster of Paris or other smooth surface coated with shellac to prevent adhesion, and having pieces of the form of the sunk ornament about ½ inch thick applied thereto in the proper positions. Then render over the inside of the mould with a coloured mortar flush with these applied forms. This coloured mortar will form the main surface of the member when finished; then float over the whole inside of the mould with another coloured mortar, which will form the sunk surface of the ornament; and then put in the concrete and reinforcement, taking care not to push any stones through to disturb the surface. If more adhesion were required between the layers of mortar and the concrete, wire or nails could be stuck into the mortar at intervals from the back as the concrete was being put in.

In cases where only a plain surface is required it may be formed as soon as possible after the removal of the falsework by the application of a rendering with a float, or by splashing it on from a brush to give a roughened surface; or a mortar may be used, with fairly large and coarse sand grains, which would leave a rough surface. Mortar applied as rendering should be of much the same richness as the concrete, otherwise the expansion and contraction will be different, with the risk of the surface becoming detached.

Another method which it seems to me would be quite a satisfactory one for buildings, especially in towns, would be to have the surface formed of faience blocks shaped at the back to connect more rigidly to the concrete. These would be placed in the falsework, with small pieces of card or felt in the joints, and the reinforcement and concrete filled in behind in the usual way. This method would have the advantage that the timber falsework would not need to be quite so carefully and expensively formed, as it has only to hold the faience blocks; it does not come in contact with the concrete; it could, moreover, be sooner struck. My idea in suggesting pieces of card or felt in the joints was to keep the joints between the faience blocks open, so that even if a slight settlement of the structure occurred, no weight would be thrown on the faience. Of course, these strips would afterwards be removed and the joints pointed up in cement. This is only a variation of the Roman methods already described.

Another treatment which has been adopted is to form the necessary beam and stanchion treatment in reinforced concrete, and to build the wall screens in the panels in brickwork or other suitable material. With that, I think, my suggestions come to an end.

I can only hope by these few suggestions to have somewhat stimulated your interest in a very large subject. Little has as yet been done to demonstrate the æsthetic possibilities of reinforced concrete; but I hope when you have the opportunity of erecting buildings in this manner of construction that you will do all you can to invent a suitable artistic treatment, and that it will not be allowed, either by architects or engineers, to be merely a cheap and always ugly or else hidden method of construction.

Mr. MATT GARBUTT proposed a vote of thanks to the author for what he termed an exceptionally able paper, and one of peculiar interest to those who, like himself, were not experts in ferro-concrete. It was therefore very good of Mr. Markham to deal with the subject from the beginning, and to touch on some of the principles which might govern attempts in treating the material in an architectural way. He felt, however, more could be made of it in large structures than in small ones, because the question of cost could not be overlooked, and in small buildings the temptation to reduce cost by reducing the thickness of the concrete covering would be rather dangerous. Doubtless concrete carefully and specially made for the purpose would stand very well, but that it would altogether resist the weather was hardly to be hoped. From the examples to be seen of Portland cement concrete work it was quite clear that with weather it deteriorated somewhat as stone did, but to an extent which must vary in individual cases. It was that difficulty, therefore, which rendered the use of a very thin covering undesirable, and in any case where a very small amount of concrete had been used between the weather and the steelwork the buildings would suffer quicker than the designers seemed to think. Of course, one way to get over that difficulty was to make the exterior faces in some form of veneer, but while that would be a legitimate method it could hardly perhaps be called a direct ferro-concrete treatment. It seemed to him the appropriate uses of the material were in

Digitized by Google

big structures, where a stronger veneer could be applied. They had seen a good many illustrations of examples of buildings in ferro-concrete—more, he supposed, than most of them had seen in situ—and it seemed to him that the difficulty pointed out in the paper—the absence of any precedent—had been felt by the designers. Most of the buildings erected were imitations of stonework and nothing else, and, as Mr. Markham had said, that was not "building in truth."

Mr. EDWIN O. SACHS, who seconded the motion, said the point he would like to bring out was that the time had arrived for the Association to seriously consider putting into its curriculum a systematic series of lectures or classes on the treatment of ferro-concrete. Students now in the Association would, all being well, be in practice for themselves in ten years' time. In ten years' time, taking the speed with which knowledge of the material was progressing, it would practically be every architect's duty to go into the subject, and the sooner they understood it the better for all of them. There was no doubt ferro-concrete had come to stay, and what they had seen illustrated on the screen from the examples of work in the United States and on the Continent really told them there was a great deal that had to be learnt, both from the designing point of view of architectural rendering in construction and the designing point of view of treatment. There was still too great a tendency to take up special systems of concrete construction. Why could not architects, he suggested, take up the design of reinforced concrete much as they would design in steel framework, and evolve their own design on the usual principles of design, and not adopt any patent system?

Mr. H. H. STATHAM supported the vote of thanks. The paper, he said, produced rather a melancholy effect upon him when he saw the various attempts of what was supposed to be the architectural treatment of ferro-concrete. It clearly showed one how very difficult it was, in dealing with materials and construction entirely different from what they were used to, for the architectural mind generally to free itself from precedent and really evolve anything that grew naturally out of the construction. He was not enthusiastic about the material and would rather it had not come to stay, but while accepting the inevitable he was sure that anything which could be called the architectural treatment of ferro-concrete was entirely in its infancy. They did not seem really to have a new treatment of architectural form arising out of the material. In the treatment of street buildings also there was a total inability to get away from the stone precedent or tradition, and if anything was to be made of the material in a truthful architectural way they would have to try more and more to shake off that old architectural tradition. It was a difficult position to take up, but until they did that and put aside everything they had learnt and began over again he did not think they would make anything like truthful architecture out of it.

Mr. J. E. FRANCK said it would be some long time before they could hope to get a really satisfactory external treatment for the new material, reinforced concrete, because it was wrong architecturally to treat any building constructed in ferro-concrete as a stone structure. Ferro-concrete should be treated as a monolithic construction, and it was not right to put up stanchions and simply fill them in. He suggested the most suitable treatment was the panel one.

Mr. F. E. MUNBY said that when the new L.C.C. Bill was passed architects would find that ferro-concrete had come to stay. Its advantages were manifest, for on an expensive site if the walls could be reduced in thickness and the floor space increased, the client would naturally be very anxious to have it adopted. As regards style, it was very difficult to know what to do. He was certain that the styles as they were used to them were not suitable to the new form of construction, and they would owe something to anyone who evolved something new. On the scientific side there must be still a great deal to learn. Even as to the concrete itself, the true nature of setting was not settled yet, and there were two main schools of thought on the question which were entirely antagonistic. The one held that setting was due to crystallisation, and the other that the drying up of the gelatinous silicates was the cause of setting.

The PRESIDENT said there was no doubt that the greatest difficulty which presented itself to architects in designing in the new form of construction was the lack of knowledge of the material itself. He had not, he said, the smallest doubt that the Association would introduce the study of reinforced concrete in its curriculum.

The vote of thanks was passed by acclamation.

Mr. MARKHAM, in some concluding remarks, cautioned architects that the various patentees of the different systems of reinforced-concrete construction were keen in maintaining their rights, and anyone who carried out such methods of building without ascertaining whether he was using a patented system or not ran considerable risk of litigation.

ROYAL ACADEMY LECTURES—ARCHITECTURE.

MR. R. T. BLOMFIELD, A.R.A., commenced on Monday his course of lectures at the Royal Academy. The subject will be "Early French Renaissance Architecture," subdivided as follows:—(1) The Italians in France, (2) The Master Builders, (3) Gaillon and the Royal Buildings, and (4) Domestic Architecture to the death of Francis I. In his opening lecture Mr. Blomfield remarked that the tradition of French Renaissance is still vital in France, and exercises a powerful influence on present-day architecture; moreover, in its long career it has produced many masterpieces. French Renaissance, or rather neo-Classic architecture in France first began in the reign of Francis I., and reached maturity in the seventeenth and eighteenth centuries. But there was no abrupt beginning, for the chapter is only one of a series in the history of French art. It is this continuity which gives it its value, for the student should look forward to future developments rather than look back upon nebulous beginnings.

French writers have expressed constantly opposing opinions as to the original authors of modern French architecture. Some say the Italians, others claim that Frenchmen played a predominant rôle. On the other hand, it might be asked whether in the buildings of Francis I. there existed an architect at all. The answer to the problem will explain, said Mr. Blomfield, certain characteristic qualities of the architecture of that period. The difficulty of obtaining one is intensified by the contemporary chaos in the mingling of old and new, as well as the uncertain position of the art itself. Mediævalism died with Louis XI. At the end of the fifteenth century France undertook disastrous French expeditions. These were a political failure, but their effects were far-reaching and permanent, and from them dates the art of modern France. The nobility learnt that the courts of Italy were pleasanter places than the ill-lit rooms of their feudal castles, and that an art infused with beauty and joyousness of life was preferable to the work of the sad and patient artists of the north.

The first attempts were sporadic and might just as well have been imported ready made from Italy. The work of the first batch of Italian artists who came to France was limited entirely to ornament, painting and carving; first-rate men were not attracted, only the failures left their native country. Moreover French craftsmen (themselves capable of work of high excellence) were indifferent if not hostile to the new influence.

Francis I. was one of the great patrons of the arts, and had a mania for building which led him into many rash enterprises. His greatest undertaking was the palace at Fontainebleau. The building work of the first contract was carried out by a French contractor with French workmen at a cost of 170,000*l*. In following on with the decoration in 1535 Italian and French artists at first worked on an equal footing. Gradually the Italians became entrusted with the more responsible and better-paid tasks, while French sculptors, ornamentalists and painters worked under their direction. The superintending genius during five years was Il Rosso. There is some uncertainty as to the control of the building from 1540, the date of Il Rosso's suicide, and the date of Primaticcio's appointment as surveyor-general by Francis II. Mr. Blomfield dealt at some length with the question as to who designed those parts of the building which show distinct variations from the general methods of the master builder, and advanced the view that not only was Serlio appointed architect to Francis I., but that he actually did design certain important parts of the building.

The list of authenticated designs by early Italian architects, i.e., of designs which by their character confirm the tradition of authorship, is of the most exiguous proportion. The reason was that till the middle of the sixteenth century the French amateur was supreme, and thought himself qualified to be his own architect. The chief sinner was Francis I., the "amateur du premier rang," who stunted architecture to mere building details, and only succeeded in introducing second-rate models. Italian artists undoubtedly familiarised Frenchmen with the words of the new language, but the latter had to learn how to use them. They did not at first master the idioms, much less the inner spirit of neo-Classic architecture.

LIVERPOOL CATHEDRAL.

THE Liverpool Cathedral executive committee held a meeting on Monday, at which Mr. Gilbert Scott, the cathedral architect, submitted a new design for the east window, which he considered would be more in harmony with the general character of the building than the original design. The new window is a four-light Gothic window of very large dimensions, being some 76 feet in height and 36 feet in width. It will therefore be the largest window in this country, and probably in Europe, and will be an exceedingly bold feature, ensuring also that the choir will be flooded with light.

Mr. Scott further presented a new design for the Lathom chapter-house, towards which the Masonic body of West Lancashire have subscribed a sum of 10,000*l*. By adopting the revised design the chapter-house can be proceeded with at once, and the cost will not greatly exceed the amount which has been raised by the Freemasons. The chapter-house is to be octagonal in form, and lighted by four large windows. Altogether it will be a charming addition to the cathedral, besides providing ample accommodation for the meetings of the chapter.

It was reported that an additional sum had been paid by the descendants of the late Sir Hardman Earle in connection with the fund for the lady chapel organ, with the object of enabling a more elaborate decorative scheme for the organ to be undertaken.

The committee accepted an offer from a lady, who does not desire her name to be published, to erect a large window in memory of her late husband, who was an original donor to the cathedral funds, and who during his lifetime took great interest in its construction.

A report was submitted as to the progress of the work during the last two months. Considerable headway has been made in the erection of the main fabric of the choir, while the roof of the lady chapel is at present being groined in stone. This is necessarily a slow operation, but it is hoped that the lady chapel will be finished within the next two years. The floor will be of green and white marble.

The annual meeting of the cathedral committee was arranged to be held at the town hall on Tuesday, March 2.

The progress made in the construction of Liverpool Cathedral during the past year is recounted in detail in the *Liverpool Diocesan Gazette*. At the close of 1907, in the cathedral proper, the choir walls on the north side had been begun, and on the other side had been carried up to 12 feet. Now the average height all over has grown to about 28 feet—an advance the magnitude of which can only be realised by taking into consideration the very large scale on which the building is planned. The width between the walls across the choir, taking in the aisles, is 86 feet 9 inches, and the length of the space in the first portion of the cathedral which will be available for services will be about 200 feet. In the lady chapel the height reached is now 56 feet, and the vaulting of the roof is steadily taking shape.

Correspondence.

[The Editor will not be responsible for the opinions expressed by Correspondents.]

What the Plumber Saw.

SIR,—I very heartily congratulate the writer of the above article which appeared in your *Contract Reporter*. It is very cleverly thought out, and should do a great amount of good in the quarter where it is most needed. It will be welcomed by the members of the Institute of Plumbers, and recognised as a faithful description of one of the many trials which cross the way of all plumbers.—Yours faithfully,

W. H.

SIR,—The article is most interesting and humorous because it has a direct bearing upon the subject. It sets forth one of the grievances from which the plumbing trade is suffering, both financially and as regards reputation. Few architects are capable of designing a drainage scheme which will meet modern requirements, and fewer still are able to design, specify and control the internal sanitary arrangements of dwelling-houses and public institutions. There however appears to be dawning in the architectural sphere a realisation of the pressing need of sanitation. But it will, I fear, be many years before the majority of architects recognise that the needs of improvements in public health are more essential than features that are pleasing to the eye as represented by the elevation of buildings, features which may prevent possibly a healthy interior.

Manchester. A TECHNICAL TEACHER.

GENERAL.

Members of the Royal Institute of British Architects are advised, by order of the Council, not to take part in the Stanley Council offices competition.

Messrs. Silcock & Reay, architects, Bath, have been awarded first place in the competition for county offices at Truro. The second and third places were awarded to Messrs. Pearson & Milburn, Chancery Lane, W.C., and to Messrs. Warwick & Hall, Gray's Inn, W.C., respectively. The assessor was Mr. Fellowes Prynne. These awards the County Council approved on Tuesday, but as the estimated cost (about 20,000*l*.) is greatly in excess of what was anticipated, the offices committee is to go into the whole matter.

The Memorial to the late Dr. Wilkinson, Bishop of St. Andrews and Primus of Scotland, will be placed in St. Ninian's Cathedral, Perth, in the form of a kneeling bronze figure, similar in design to the statue of Archbishop Benson in Canterbury Cathedral.

The Cambridge Antiquarian Society has passed a new law whereby "Members of the University of less than M.A. standing, and students of the same standing at Girton and Newnham Colleges, may attend the general meetings of the Society without introduction. Such persons may also become associates of the Society on payment of a subscription of 10*s*. 6*d*. per annum, which shall be due on January 1 in each year."

The Late Mr. James Duncan, of Jordanstone, Alyth, N.B., has bequeathed a part of the residue of his estate for the founding of a school of industrial art in Dundee. The amount of money available for the purpose is estimated at 60,000*l*., not more than half of which is to be used for buildings. Under the provisions of the will the school will be managed in connection with University College, Dundee, and the Technical Institute, the idea of the testator being that there should be no overlapping as a result of his bequest.

Mr. E. A. L. Ould, F.R.I.B.A., died at his residence in Boughton, Chester, on Sunday. Deceased was articled to a firm of architects in York, and afterwards acted as an improver with Mr. John Douglas, of Abbey Square, Chester. About 1883 he started business in Bridge Street Row, Chester. Over twenty years ago he joined Mr. G. E. Grayson, and, since the latter's retirement, Mr. Ould has been in partnership with Mr. Hastwell Grayson for about twelve years, carrying on business as Grayson & Ould, at 31 St. James Street, Liverpool. The deceased gentleman was one of the leading domestic architects in the North of England with a strong partiality for half-timbered work. He designed dwellings for Mr. James Lever at Thornton Hough, for Sir Alfred Hickman near Wolverhampton, a large house at Tattenhall, the Bank of Liverpool at Crosby, Bidston Court, and Bryn Estyn, near Wrexham. Woolton Church and St. Mary's, Liscard, were also from his plans. In connection with Mr. Hastwell Grayson, he was responsible for the designs of the secondary schools at Aigburth Vale, three or four other secondary schools in Cumberland, the Liverpool Hospital for Consumptives, Port Sunlight Hospital, and about 300 of the dwellings at Port Sunlight. Mr. Ould was a past president of the Liverpool Architectural Society.

Under the Auspices of the West of Scotland branch of the Garden City Association an exhibition of cottage designs has been opened in the rooms of the Scottish Guild of Handicraft, Ltd., Sauchiehall Street, Glasgow. A hundred sets of plans are on view. The following are the prize-winners of the various classes:—Class 1—For best all-round design for cottages to cost 400*l*.—Gardner & Millar, 144 St. Vincent Street. Class 2—Cottages of three or four apartments—A. Wingate, 131 West Regent Street. Class 3—For small holding groups—James Chalmers, 93 Hope Street. For economy in planning — Class 1 — Gardner & Millar, 144 St. Vincent Street. Class 2—James Chalmers, 93 Hope Street. All of Glasgow.

Jedburgh Abbey is one of the most important historical monuments in Scotland. Up till about 1870 the greater part of the nave was used as a parish church, and this was the cause of much damage to the masonwork. Since then, with the exception of part of the north transept, it has been roofless. When the new parish church was erected the nave was cleared out, and considerable repairs were executed. During the last six months a thorough examination and repairing has been going on under the superintendence of Sir Rowand Anderson.

The Architect.

THE WEEK.

THE ceremonial visit of our King and Queen to Berlin has focussed our attention on Germany during the past week, and hence we have been more ready to take note of the disastrous floods that have been practically universal in that country. The rivers of Central Europe are largely fed from snow-clad mountains, which, under normal conditions, store up during the winter the supply that keeps them from too great diminution of flow during the summer. Usually it is in the month of May that the greatest volume of thaw-released water comes down from the melting snow and glaciers of the mountains. Then is the best time for tourists to enjoy the waterfalls and mountain torrents that lend so much charm to the St. Gothard route, for example. The snowfall that we had last month and the sudden thaw that we have lately experienced have both been more pronounced on the Continent, with the result that the Danube, the Oder, the Elbe, the Main, and the Rhine, and their tributaries have been unable to carry off fast enough the rush of melting snow and ice. Nuremberg is flooded, and the Frauen Kirche is an island. Dresden, Frankfort-on-Main, Leipzic, and Ratisbon, and many other smaller towns that are our happy sketching grounds are in a like condition.

ON the Continent the inland waterways receive far more attention from paternal governments than in our own happy-go-lucky island, but even this greater care and concern for the health and property of their peoples has not sufficed to avert the sudden onslaught. The condition of our own neglected rivers is a standing disgrace, and it is high time that a central government department was instituted for the prevention of floods and the proper conservation of the water that we receive from our rainfalls, which at present is allowed to work its own sweet will in causing damage, and waste its value by rushing down to the sea with as much celerity as possible.

AT the meetings of the Association of Technical Institutions on Friday and Saturday last some points of importance were brought forward. The new President of the Association, Mr. GEORGE T. BEILBY, of Glasgow, in his opening address urged that technical institutions should associate themselves more closely with industrial interests and give to the practical side of their teaching the same kind of reality that was found in the clinical education of medical students. Mr. BEILBY, as an industrial chemist, very naturally illustrated his argument by reference to the chemical industries, but as regards architecture, we should strongly advise that the Polytechnics and similar institutions, in London at any rate, should drop their attempt to train architects or to teach architecture, so vastly inferior are they to the work done at the Architectural Association, at University and King's Colleges. Let them devote their attention to the turning out of efficient craftsmen—bricklayers, masons, plumbers, plasterers, and so on. By all means let them throw open instruction in this direction to any embryo architect who desires to obtain, what is no doubt valuable, an insight into the practical craftsmanship of the building trade at first hand.

ANOTHER point of Mr. BEILBY'S address was the desirability of making available the technical institutions for the purpose of research as well as for instruction. With this we cordially agree, and the London Polytechnics would be doing a good work for architecture and the building trade if they adopted the suggestion of Mr. BEILBY. There are not a few architects in London who have a penchant for science, and would doubtless welcome the opportunity of carrying out experiments to test the feasibility of ideas that occur to them in connection with building materials and construction, for which the chemical, physical, and testing laboratories with which many of our London institutions are so admirably equipped might advantageously afford facilities. As far as our observation goes many of these expensive laboratories are not used to anything like the extent that they should be to justify the expenditure of public money that has been made upon them. The rate-paying architects of London have helped to pay for these, and it is, we claim, their right to be allowed to enhance their usefulness.

THE growing scarcity of timber means more in the world's history than an inconvenient shortage of supply in a useful building material which from habit we have come to regard as indispensable. It means the growth of the desert places of the earth, partly, perhaps, the result and evidence of the drying-up of our planet's moisture, which, if Professor LOWELL'S latest explanation of the phenomena of Mars is correct, must in the future extinguish all life in our world, as, according to the scientist, is visibly the process, progressing to finality in the ruddy planet. We do not pretend to set up our scientific knowledge against that of so eminent a man as Professor LOWELL, but it occurs to us to ask whether, if Mars is losing its water, it is not also losing its weight, and if this be so, how both it and our own habitat are to maintain their positions in the universe? Undoubtedly the deserts of our world are increasing in magnitude, for within the last 2,000 years the Roman cities of North Africa have lost the sources of water supply that fed their aqueducts, and the great desert of Central Asia has obliterated the life of a flourishing civilisation. The condition of the bad lands of Arizona and the central waste of Australia at the same past date are not matters of history, but it is clear that Arizona at least was at one time forest. With regard to Palestine, no longer flowing with milk and honey, we are on more certain ground. It is generally admitted that the cutting down of its timber trees has reduced this part of the world from a well-watered and flourishing agricultural and pastoral country to a comparative desert, and such a sequence may be assuredly prophesied to the denudation of the forest lands that still remain in the world.

AS an example of *ex parte* argument and the selection of data to support a theory, it would be difficult to surpass the use that has been made of the report of the Royal Commission on Sewage Disposal Plants in Great Britain by the opponents of Toronto's proposed sewage works. Selecting statements relating to septic "tanks worked at a twenty-four-hours rate" it was asserted that by the proposed scheme some 50 per cent. of the solids in the sewage would be deposited in the lake and would contaminate the water, thus ignoring the conclusion of the Commissioners quoted in *The Architect*, September 11, 1908, Supplement, p. 21:—"We are satisfied that it is practicable to purify the sewage of towns to any degree required, either by land treatment or by artificial filters, and that there is no essential difference between the two processes, for in each case the purification, so far as it is not mechanical, is chiefly effected by means of micro-organisms." The attempt thus made to discredit entirely the use of septic tanks may possibly be repeated elsewhere by interested parties, and we therefore think it desirable to again call attention to the finding of the Commissioners.

THE operation of the Patents and Designs Act of 1907 is already benefiting the building trade, as numerous foreign patentees have been, and others are being, forced to erect factories here for producing their protected manufactures. This development is of the further advantage to architects and their clients that the vexations and inconvenience caused by the delays in transit and supply of goods "made in Germany" are likely to be now very much minimised.

THE FIRE RISK OF LONDON'S PUBLIC BUILDINGS.

THE unpreparedness of some of London's most valued public buildings, such as St. Paul's Cathedral, Westminster Abbey, and the British Museum, to adequately and promptly cope with an outbreak of fire is simply appalling. Take the case of St. Paul's. Everyone knows that our great Metropolitan cathedral, of which every Londoner is justly proud, is surrounded by high buildings, used as warehouses and shops for the dry goods trade, and crammed with highly combustible materials. If a fire broke out in one of these, as it might readily do, and a favourable breeze were blowing, masses of burning material would be blown on to the roof and dome of St. Paul's. Every architect knows that the roofs are formed partly with flats, the high parapet walls of which constitute them veritable pockets admirably adapted for the reception of burning fragments, and that both they and the dome (the most beautiful in Christendom), which looks so great and solid, are formed with sheets of lead, laid on boarding, and supported by a forest of bone-dry timber that would burn like matchwood if once it were set alight. Everything, therefore, is ready for a conflagration, and if the dome once fairly caught fire and were not promptly extinguished the whole would speedily be ablaze. Molten lead and falling timbers would probably soon overcome the resistance of the brick cone which carries the stone lantern; this would collapse, and in its fall would crash through the inner dome, and the whole burning mass would be precipitated into the interior of the church, and St. Paul's Cathedral would be doomed. How are we prepared to avert such a catastrophe? We are all proud of our Fire Brigade, and fully recognise the bravery and skill of its officers and men: but although its personnel has been largely increased and the efficiency and power of its apparatus has been considerably augmented since it has been under the charge of the London County Council, it is still far from being sufficient for the eventualities that might occur in our great Metropolis. Any really serious conflagration necessitates a "brigade call," when every available man and engine is pressed into service.

It is within the region of possibilities that the brigade might be confronted simultaneously with a Cripplegate fire and a Tooley Street fire, and it is quite unable to cope with two such assaults at once. Or, again, it is quite a possible contingency that while the brigade was engaged in a hard fight with a conflagration at, say, Messrs. WHITELEY'S premises at Bayswater, one of the great warehouses around St. Paul's might burst into flames. In such a dire event the cathedral would stand a small chance of being adequately defended.

Even if the brigade was at liberty to give its whole attention to a fire in the dome of St. Paul's, what sort of a chance has it of success? Water towers and powerful engines have largely increased the capabilities of the brigade, but we all know that every foot additional length of hose diminishes the pressure that the engine supplies. The engines must remain on the ground level, and the top of the cathedral dome is 365 feet from the ground. Anything that is humanly possible the men of our London Fire Brigade will do, but there are limits to the capabilities of both men and material.

St. Paul's Cathedral, then, should be so equipped that an outbreak of fire can be dealt with at once in the absence of the Fire Brigade. How is it equipped? There are water tanks in the dome, supplied with rainwater, and two tanks on a level with the top of the organ, from which a number of hydrants are fed. Necessarily these tanks cannot furnish sufficient pressure to throw a jet of water on to the dome, and, in fact, we believe that their utmost capacity is to reach the level of the stone gallery. In winter these tanks and the pipes from them are frequently frozen, and they are inoperative.

Some towns, like Brighton, have sufficient pressure in the ordinary supply mains of the street to render fire engines almost unnecessary; but London is not in that happy position. Even Manchester, which has a far higher pressure than London in its street mains, has not sufficient to entirely dispense with fire engines. If the hydrants in St. Paul's are connected direct with the mains of the Metropolitan Water Board the pressure, therefore, would not be anything like enough to safeguard the cathedral.

To summarise—the position of St. Paul's Cathedral in respect of fire risk is this: it is exceptionally exposed to the danger of fire; it is insufficiently equipped to combat fire by its own resources, and must depend on the Fire Brigade, the magnitude of whose responsibility is sufficient to prevent it from being able to render assistance; with the whole force of the brigade available it is scarcely possible for its power to save the dome of St. Paul's from destruction.

Westminster Abbey and the British Museum are not, perhaps, exposed to such imminent danger of fire, but their means of quenching it are also insufficient and inadequate.

In quelling an outbreak of fire and preventing its spread two things are of primary importance, promptness and power. In its early stages a fire is easily extinguished by a very small amount of water forcibly applied. A siphon of soda-water is a very admirable fire extinguisher promptly used, partly, no doubt, by reason of the carbonic acid gas it contains, but largely from the force with which its jet is propelled. An ordinary two-gallon pail, or even a common quart jug of water forcibly thrown will extinguish quite a respectable blaze.

Our London Fire Brigade is commendable for the celerity of its turn-outs, and if an alarm were given from St. Paul's Cathedral the men of the Watling Street and Cannon Street stations would quickly be ready to start. But our City streets are apt to be congested with traffic, and the engines might be delayed, or, worse still, might be busily engaged in fighting a conflagration miles away. What, therefore, is wanted is an equipment at the cathedral itself capable of attacking an incipient fire promptly and forcibly.

Fortunately engineering skill and commercial enterprise have placed the opportunity of installing such an equipment in the hands of the Dean and Chapter. The mains of the London Hydraulic Power Company are at the very door of St. Paul's Cathedral, of Westminster Abbey, and of the British Museum. The hundred and sixty miles of mains that the company has laid through the greater part of London are primarily intended for the supply of power for the working of lifts and other machinery, but they are also eminently suitable for protection from fire.

The prime essential for this purpose is reliability, and to this point we first directed our attention in our investigation of the facilities for fire extinction that the company has to offer. For the purposes of its ordinary business it is necessary for the company to ensure a pressure of 700 lbs. per square inch at any point in its mains at any time of day or night, under any conceivable demand. To provide this assurance it has established six pumping stations, all mutually connected, so that should any one break down the others will take up its work, while flexibility of response to varying demand is obtained by the automatically reciprocal character of the engines, which work faster when a call is made upon their energy, and slow down when the demand slackens.

It would be quite possible for the company to take a main to the top of the cross on the dome of St. Paul's and there deliver a jet of water at a pressure per square inch higher than any ordinary fire hose would stand. Such, however, would not be the best method of utilising the hydraulic power for fire extinction. This is far better done by using an injector fire hydrant, which is connected to the power mains and also to the water supply mains, or to tanks, and from which a combined jet of great force and volume is passed through the ordinary hose and nozzle.

The next point that occurred to us was that the great pressure at which the hydraulic power is maintained would be too great for any existing installation at present worked from the mains of the Metropolitan Water Board; but we learn that by the use of ELLINGTON'S patent automatic apparatus the pressure in the delivery hose can be regulated to any desired figure.

Another advantage that the system possesses is that it is by no means necessary to keep the rising mains supplying

Digitized by Google

the hydrants always full of water, so that the disadvantage under which the present hydrants at St. Paul's labour of a liability to be frozen out of their supply is obviated, as the control of the supply can be arranged in the basement or any other convenient place.

Every building in London within the field of the Hydraulic Power Company's operations can thus be fitted, so to speak, with its own fire engine, always and instantly ready for use with any amount of power deemed advisable.

Now comes the question of cost. We do not know for what amount St. Paul's Cathedral is insured, or whether it is insured at all, but we can form an opinion as to the amount for which it ought to be insured and of the premium for that insurance, and, in our opinion, the amount of one year's premium would suffice for a very efficient installation of hydrants and injectors.

The working costs are, for fire service, quite small, as the consumption of hydraulic power is infinitesimal until it is urgently required for the extinction of fire, and even with the monthly test that Capt. HAMILTON recommends for all private installations of fire extinguishing apparatus, we doubt if the annual cost of an efficient set of hydrants at St. Paul's Cathedral would amount to 50*l*. The safety from fire of our beautiful Metropolitan cathedral would be cheaply purchased if the expense on both capital and maintenance account were ten times what it would be if the system we advocate, in the public interest, were adopted.

ARCHITECTURE: ITS TRUE PRINCIPLES.—III.

By R. OWEN ALLSOP.

NOVELTY IN DESIGN.

FOLLOWING our train of thought, and pursuing the argument, we should doubtless arrive at the conclusion that, not architecture, but the architect, is at fault. While we have eyes to see, and understanding to comprehend, it must be the case of the workman complaining of his tools, and ignoring the question of his own ability; for even in architecture composed of new combinations of that which is itself old, there exists an infinity of variety. Yet to draw a comparison between architecture and literature, we continue to copy old set phrases, of which the producer is as wearied as is the beholder or the reader. "Never imitate," says EMERSON; "your own gift you can present every moment with the cumulative force of a whole life's cultivation; but of the adopted talent of another, you have only an extemporaneous, half possession."

Between design and invention is much that is common. Both are the result of the power of reason. They

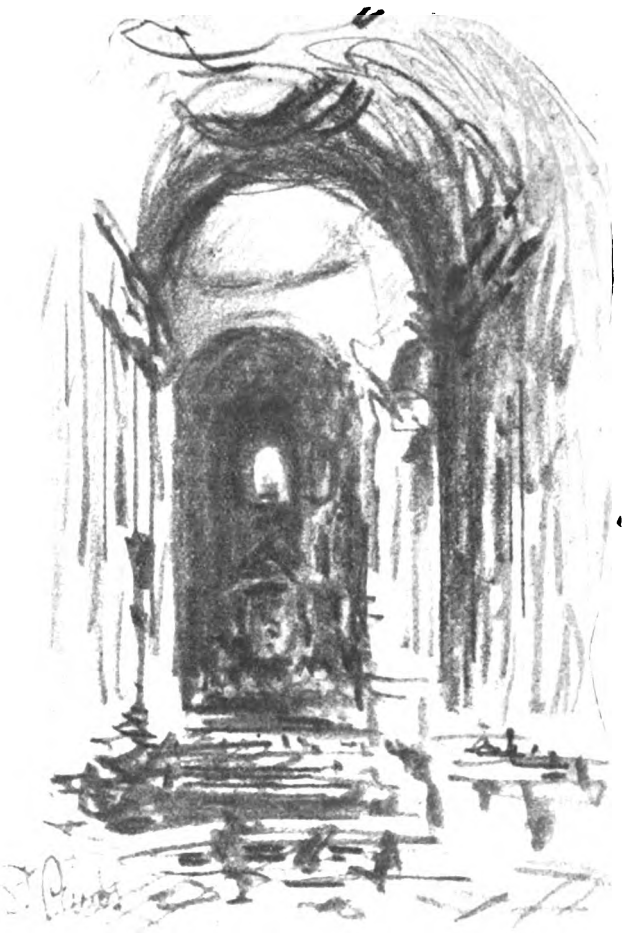

FIG. 8.—ST. PAUL'S.

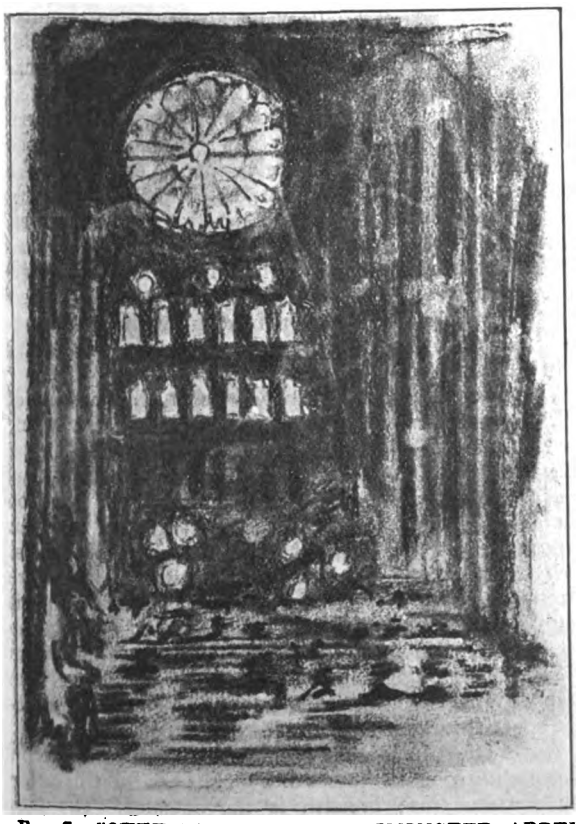

FIG. 7.—SOUTH TRANSEPT, WESTMINSTER ABBEY.

are therefore the product of the highest of the faculties, and require, as handmaid, the co-operation of imagination. As concerning patent law, the first essential of invention is novelty. It is an understood corollary that there is also utility. This must be applicable in the full to design proper, for apart from the usefulness of a house to serve the practical wants of man, the design of, say its ceilings, is useful for his entertainment. The two classes of usefulness, service and delight, cannot be separated in architecture. For, if this be done, we have on the one hand a building (which is not architecture) and on the other a monument, as such, unless indeed we are to argue that an Eleanor cross serves the practical purpose of commemorating a certain happening.

The necessity for invention in all except the purely imitative arts (if indeed such really exist) falls in with GARBETT'S remark, that it is the brain we admire in a work of architecture. Hence all machine reproductions are at once put without the pale. The stock baluster turned out by an automatic machine has nothing correlative to art. All that may concern it of the artistic is the effect of its grouping, and here we have an instance of how new combinations may instal something of the artistic even to work that in itself may be hopelessly vulgarised by countless repetitions. It is colloquially said "It is vulgar to imitate," and here it is vulgar to reproduce all forms, large or small, when such reproduction arises from a barren, unfertile mind. In all imitation is some mockery. Invention and imagination, which, in some senses, are synonymous, are what is needed in architectural design; but the invention must be useful (it is useful if beautiful) and the imagination founded on

Digitized by Google

right reasoning. Imagination, out of control and restraint, is a disease, the chief feature of madness. A host of disorderly notions, writes CERVANTES, crowded through the brain of DON QUIXOTE. Contrary to a general idea, a kind of invention and a kind of imagination—hence an idea of novelty—is quite a common attribute of many persons. What more easy than to take a façade on paper and turn "inside out" the whole of the details? It is done unknowingly by the unskilful draughtsman, who thinks he is copying exactly, but in reality produces a copy different in every respect from the original. If there is any art in the copying of an old "Order" it must reside solely in the fact that only the trained eye can correctly copy. Hence there is art, but it is the art of the accomplished copyist; and as we have suggested before, a machine could be constructed to do this, indeed has been, in the automatic wood-carver actually rendered in every sense of the word a "commercial" article.

To what part of the architect's art can invention be applied? We might more reasonably ask, to what part can it not be applied? It may be applied to a plan, to a mass, to grouping, to details, to all. It is what we want. But the first essential of fitness, suitability and usefulness for service or delight, is apparently the stumbling-block. No one wants an old-time capital turned upside down for mere sake of effect. We should probably differentiate between true invention and a fraudulent substitute, a mere parasite, or, possibly, a parody of the real article. Invention presupposes the power of imaginative conception. A spurious invention could be more properly described as an alteration. Alteration is just what we want to avoid. It is the alterator who alters for mere sake of alteration that we have to thank for abortive art production. The true inventor conceives: he grasps the object of invention before it has materialised. This seeing with the mind's eye is a faculty required first and foremost of all designers, and if this is required in matters of detail, much more is it needed in questions concerning massing, if the result of the mass is to be unity.

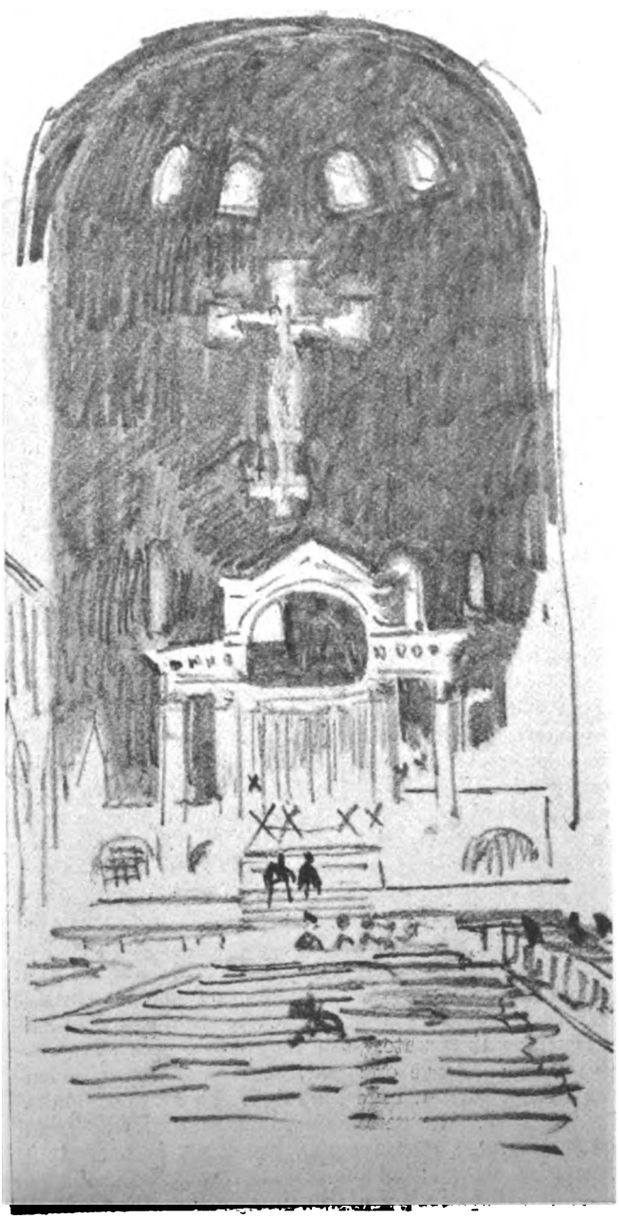

FIG. 9.—WESTMINSTER CATHEDRAL.

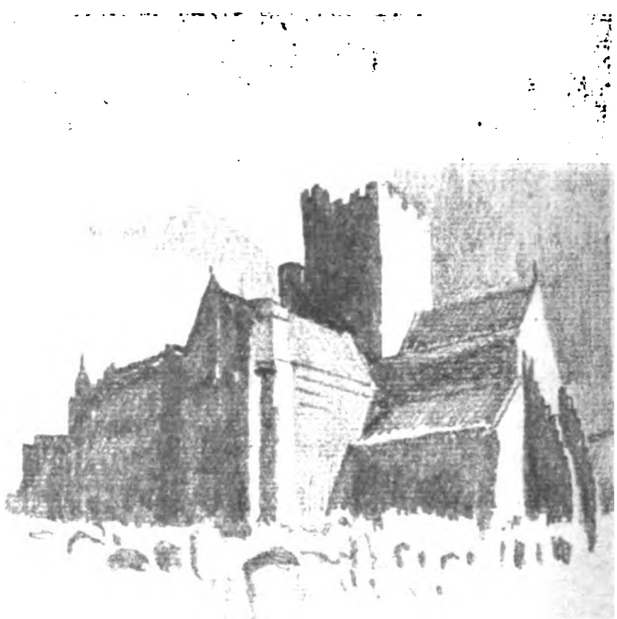

FIG. 10.—CARLISLE.

The novel effects of picture-painting arise chiefly from the new arrangements of old parts. It would seem that art, like science, must have its unchangeable primitive components. We have heard of late of the "molecular architecture" of chemistry. Such chemical building has for its stones and bricks the ultimate particles of matter. All varying forms are assumed to be composed of variation in parts. An original (new) chemical compound thus becomes a new, definitely-grouped structure. All art, then, seems to be variant, not by change of whole but by variation of the part. Therefore, we need not feel necessarily disconcerted at having to employ an old architectural feature, so long as there is freedom to form novel massing—new groups. Providing that the part is itself beautiful, we have no reason in complaining of its constant reappearance any more than we weary of the regular nightly reappearance of the moon.

Invention and imagination applied to the massing of architectural features seems the great present want. Composition, as meaning the placing together of parts, rather than design (suggesting the arrangement of surfaces), is the kind of study needed at the present day. Too much elevation drawing and competition work has been responsible for the lack of large and dignified effects. How many splendid corner sites are wasted by failure to make legitimate use of the external angle; although it may be any amount of flat elevational work is put in the façades. It is in interesting composition that the works of Sir CHRISTOPHER WREN are so distinguished. The perspective of WREN's compositions is always interesting, apart from any special ornamental detail.

Novel effect in interior architecture must be sought in the grouping of main masses of light and shade. Character results from this; breadth is the outcome. The fact sufficiently explains why it is that, in the roughest sketch, if some regard is paid to main masses, an impression is given which we recognise as pertaining to a particular

Digitized by Google

building and to that alone. The rose window and contrasting lights below dominate the view of the south transept at Westminster Abbey. As sovereigns are worth more than shillings, so main impressions, conveyable to the mind, are more valuable assets to the architect than mere details. If these latter are coarse and unsuitable and void of vigour of conception and execution, by so much the work is depreciated in value; but one rarely, if ever, discovers insensibility to refinement in small matters in minds fitted to grasp broad effects. Where all attention is absorbed in producing form as distinct from producing effect from form, main impressions are overlooked. The broad effect of the view eastwards in St. Paul's concerns the contrasting light and shade of nave, crossing and choir. If our sketch gives any savour of this main effect, it is plain that details do not concern this, since if there can be said to be any detail whatever it may be safely designated as unlike any detail known to the student of architecture, let alone what is actually to be found in the cathedral. The mass closing the eastern prospect in John F. Bentley's Westminster Cathedral has marked individuality, even omitting the outline of the semi-dome over the choir, which is barely visible in a half light.

In studying buildings in the mass it is not at first easy to judge of the value and effect of great parts, the smaller ones persistently obtruding on the mind. A little practice enables one to see through, or in spite of, this, and to reduce the view mentally to an effect such as represented in fig. 10. In making such a drawing it is not always easy to determine what to show and what to leave out. The truth seems to be that it is impossible to make a drawing of this kind with absolute justice to the building as a whole, offering itself for consideration as a whole, and not expecting to be robbed of its minor features. The difficulty is especially felt if endeavour be made to produce an accurate line drawing. The reason would appear to be that in true architecture details grow into parts and parts into wholes, as a contradistinction to something applied—stuck on—and that the same difficulty is encountered as would be found if endeavour were made to give the effect of a rose-

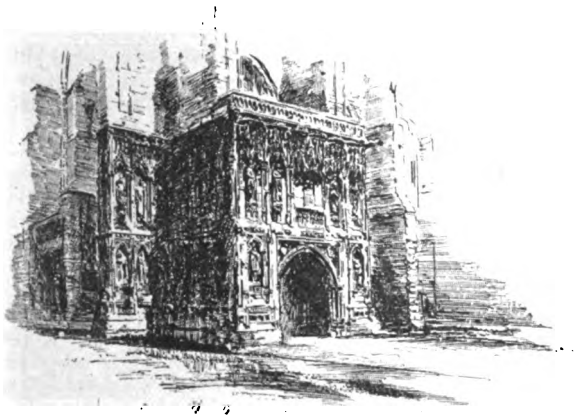

Fig. 11.—SOUTH PORCH, CANTERBURY.

bush with its blossoms and foliage lopped off. A compromise requires to be here and there effected, and, generally, suggestiveness aimed at. It is further noteworthy that if a building as a whole may be considered to comprise (1) main massing, (2) minor massing and (3) detail, in like manner is composed not only each subordinate part but also the detail itself. Thus the south porch of Canterbury Cathedral is a detail of the whole; yet it may also be viewed as a separate little building, and, whether we take the one or the other view, is resolvable into main mass, subordinate grouping and detail. Whether or no it is possible to make satisfactory drawings representing elaborate architecture with detail eliminated, the fact remains that these main masses exist, and, according to their nature, are potent for good or evil. If the former, they are the first cause of powerful effect upon the beholder, while if the latter, no amount of architectural form will ever remedy the prime defect—loss of character.

(To be continued.)

THE WORKMEN'S COMPENSATION ACT (1906) IN OPERATION.—IV.

By W. S. Holdsworth, D.C.L.

Cases Turning upon the Definition of Certain Terms.

The Casual Workman.

THE Act provides, section 13, that the term "workman" does not include "a person whose employment is of a casual nature, and who is employed otherwise than for the purposes of the employer's trade or business." In other words, an employer is not liable to compensate such persons if they are injured by an accident in the course of their employment. Two cases have recently been decided upon the meaning to be attached to the phrase "employment of a casual nature." In the case of Hill *v.* Begg * the appellant, a stockbroker, for about two years previously had been in the habit of employing a man to clean the windows of his private house. He sent a post card for him when he wanted him, and paid him when he had finished his job. He was under no obligation to employ him any more than any other person. The man was killed by an accident while engaged in cleaning windows. The Court of Appeal held that the person was a casual workman employed otherwise than for the purposes of the employer's trade or business, and that no claim to compensation arose. As Cozens-Hardy, M.R., said, it would be difficult to frame a definition of a casual labourer which would not cover this case. He pointed out that a broad distinction was taken by the Act. If a man employs another for the purposes of his trade or business, e.g. a dock labourer, it is immaterial that his employment is of a casual nature: if a man employs another for domestic purposes, the casual nature of the employment makes all the difference. As Buckley, L.J., pointed out, the case was analogous to that of a man who is in the habit of employing the same waiters when he from time to time gives a dinner or a reception. "In such a case the waiters may not incorrectly be said to be regularly employed in an employment of a casual nature." The second of these cases is that of Dewhurst *v.* Mather.† In that case a woman did washing for an employer at her house every Friday and on alternate Tuesdays. She worked for other persons on other days. While working for the respondent she pricked her thumb, got blood poisoning, and lost the use of her hand. It was held that this was not a case of casual employment—"There was a contract of service of a periodical nature." Under these circumstances the provisions of schedule 1, section 1, subsection 1 (*b*) applied. By virtue of this section, where the claimant has "entered into concurrent contracts of service with two or more employers, under which he worked at one time for one such employer, and another time for another such employer, his average weekly earnings shall be computed as if his earnings under all such contracts were earnings in the employment of the employer for whom he was working at the time of the accident." As the woman earned 15*s.* a week she was awarded compensation at the rate of 7*s.* a week.

The Sub-contractor.

Section 4 of the Act contains a long and somewhat complicated clause designed to give the workman injured by an accident a right of recourse either against the principal contractor or the sub-contractor. In substance the section runs as follows:—When any person (called the principal) for the purposes of his trade or business contracts with any other person (called the contractor) for the execution by or under the contractor of the whole or any part of any work undertaken by the principal, the principal shall be liable to a workman as if that workman had been employed immediately by himself—the rate of compensation to be ascertained by reference to the earnings of the workman under the contractor. This is the main idea of the section; but the generality of its terms is modified by the following provisoes:—(1) If the contract relates to threshing, ploughing, or other agricultural work, and the contractor provides machinery for this work driven by mechanical power, he only is liable. (2) The principal who is liable to pay compensation is entitled to be indemnified by the contractor. (3) There is no liability on the principal "in any case where the accident occurred elsewhere than on, or in, or about premises on which the principal has undertaken to execute the work, or which are otherwise under his control or management."

A case which illustrates this last proviso is the case of Andrews *v.* Andrews and Mears.‡ Mears contracted to do

* 1908 2 K.B. 802; 24 T. L. R. 711.
† 1908 2 K.B. 754; 24 T. L. R. 819.
‡ 1908 2 K.B. 567; 24 T. L. R. 709.

Digitized by Google

certain work in connection with paving near Albert Hall, Knightsbridge. The work was to cart sand to Knightsbridge, and to cart rubbish from the job to a shoot belonging to Mears at Stamford Green. Mears made a sub-contract with Andrews to take away the rubbish and shoot it where he pleased. Andrews employed his son Andrews to do the carting. While so engaged he went to sleep, fell off the cart, and was killed. At the time, the rubbish was being taken, not to Mears's shoot, but to some other place. The County Court Judge held that both Mears and Andrews the father were liable to pay compensation to the dependants of Andrews the son; but the Court of Appeal reversed this decision, on the ground that it fell within this proviso. As Cozens-Hardy, M.R., pointed out, it would be quite absurd to say that all the roads radiating from the Albert Hall to any distance that the sub-contractor liked to take his cart were premises on which the principal had undertaken to execute the work, or that they were under his control or management.

There has not as yet been any general discussion of the section as a whole. But quite recently certain points have been considered by the Court of Appeal in the case of Mulrooney *v.* Todd and the Lord Mayor, &c., of Bradford.* In this case the Bradford Corporation bought a plot of land adjoining one of their markets. On this land there was an old mill. Todd contracted with the Corporation to clear the site, paying the Corporation 15*l.* for the bricks. While the work was going on one of Todd's men was killed. His widow sued Todd and the Corporation, relying on the provisions of sections 4 and 13 of the Act. Section 4 we have explained above. The material part of section 13 runs as follows:—"The exercise and performance of the powers and duties of a local or other public authority shall, for the purposes of this Act, be treated as the trade or business of the authority." In answer to this claim the defendants contended in the first place that section 4 applied only where there was a contract and a sub-contract. There was clearly no contract and sub-contract, for the Corporation were acting not as a contractor, but as an owner. The Court, however, refused to accede to this argument, pointing out that proviso 1, set out above, in relation to agricultural work, negatived this construction. In the second place it was contended that this was not a contract of employment at all, but a contract for the sale of goods, and therefore it was wholly outside the Act. No doubt there is much authority for the proposition that any contract which involves the transference of property from one contracting party to the other is a contract of sale But though, as we have noted above,† certain technical rules and presumptions of the common law have been allowed to operate to the disfavour of the employer, this particular technicality, which would have operated to the disfavour of the workman, was not allowed to prevail. The Court said simply that, looking at the whole transaction, it could not be regarded as primarily a contract for the sale of goods, a statement which is true of other cases which have nevertheless been held to be cases of sale. This, as we have said above, is the proper way to interpret the Act; and if this mode of interpreting the Act had been universally applied it is doubtful whether some of the decisions on the question of dependency would stand. In the result, therefore, the claim was upheld. But the Court expressly said that it was only a decision in the case of a municipal Corporation, and that it did not follow that the same reasoning would be applicable in the case of a private trader. The result is that many points relating to the application of this section 4 still await an authoritative construction.

The term "Workman."

Section 13 of the Act contains the definition of the term "workman." It does not include, as we have seen, the casual labourer unless employed for the purposes of his employer's trade or business; nor does it include a member of the police force, or an outworker,‡ or a member of the employer's family living in his house. It does include "any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise," subject, however, to this qualification, that if the service is not manual labour the total earnings must not exceed 250*l.* a year.

Just as we must reckon the value of board, lodging, and other allowances to arrive at the earnings of the workman,* so, under this section, we must make a similar calculation to find out whether the income of an applicant employed on other than manual labour exceeds the 250*l.* a year. Thus in the case of Dothie *v.* MacAndrew & Co.† it was held that the widow and children of a ship's captain, accidentally killed by a tramcar at the port of Antwerp, where his ship was docked, would fail in their claim, though the deceased's wages were only 216*l.* a year, if the value of his board provided by the owners brought his income over the statutory sum; and it was held that the proper test of the value of such board and lodging was, not what the captain saved by these allowances, nor what it would have cost the captain to provide his own board, but what the style of board provided by the owners would have cost him if he had had to purchase it himself. It would seem therefore that while for the purpose of reckoning the earnings of a workman to ascertain the amount of compensation due the value of such allowances is in many cases their cost to the employer,‡ for the purposes of reckoning the earnings of a workman to ascertain whether he falls within the Act, the value of such allowances is what the cost of similar allowances would have been to the workman.

It should be noted that the Act does not provide for the case where a man engaged on other than manual labour works for several employers and is paid by each a sum under 250*l.* a year. Is it possible to add together his total earnings so as to put him outside the Act? If we take the analogy of the converse case the answer should be yes. As we have seen, schedule 1, section 2 (*b*) provides that for the purpose of assessing the average weekly earnings of a claimant who works concurrently for two employers at different times, the earnings under all these contracts are to be added together and treated as if they were earnings in the service of the employer for whom he was working at the time of the accident. There does not seem to be any reason why this principle should not be applied in the converse case. But as yet nothing has been decided on this point.

Under the old Act there was no such comprehensive definition of the term "workman," and questions sometimes arose as to doubtful cases. One of these cases, Simpson *v.* the Ebbw Vale Steel, Iron and Coal Company,§ was commented on in *The Architect*, March 24, 1905. It decided that the manager of a mine at a salary of 400*l.* did not come within the Act. More recently in the case of Bagnall *v.* Levinstein, Ltd.,‖ it was decided (Farwell, L.J., dissenting) that a man who had taken a degree in science employed in a dye and chemical works at a salary, and commission on profits on his inventions and improvements, was not a workman within the old Act. The ground of the decision was that the man, though occasionally doing manual work, was not employed as a workman, but rather as a skilled expert. But probably difficult questions of this kind can but rarely arise under the present Act. Its definition of a workman is far more detailed, and the limit of 250*l.* a year, which it fixes for those not engaged in manual labour, will obviate the necessity for speculation as to the status of many who, though apparently coming within the words of the Act, are not workmen in the popular sense of the term. It may, however, be noted that some difficult questions may arise where a person earning over 250*l.* a year does any considerable amount of manual work. In such cases it may be necessary to have recourse to the reasoning employed in these cases. No doubt the test will be the character of the employment. The fact that the applicant does some manual work will not, as the last-cited case decided, be taken as conclusive.

It cannot be doubted but that the more comprehensive terms of the Act of 1906 have settled many difficult and doubtful questions which arose under the more limited provisions of the older Act. Though some of the provisions of the Act—e.g. those with regard to serious and wilful misconduct, and those with regard to illegitimate children—favour the workman unduly; though, as we have pointed out above, some of the decisions seem to go rather far in the same direction; yet it cannot be doubted but that the Court of Appeal have in general interpreted it according to its spirit. The governing idea has been to interpret its

words and clauses in accordance with the ordinary and popular meaning of the terms used; and their work may in the future provide a basis for a final or almost final codifying Act. It has been said that one half of the world does not know how the other half lives. The cases decided under this Act give to lawyers a somewhat detailed and practical knowledge of this matter—a knowledge which will doubtless indirectly assist them in administering other branches of the law, for it helps to keep their minds in touch with the realities of many different spheres of social life. "Law," said the late Professor Maitland, "is the place where life and logic meet;" and at all periods in our legal history a knowledge of life has helped to free the mind from too absolute a subservience to the abstractions of logic.

ROYAL ACADEMY LECTURES—ARCHITECTURE.

IN the second of a series of lectures on "Early French Renaissance Architecture," Professor Reginald Blomfield, A.R.A., dealt with the master builders. He pointed out that French writers differed as to the position of these men, one school treating them as simple workmen, the other describing them in terms of exuberant eloquence as accomplished architects. A similar difference of opinion existed in regard to certain English builders of the sixteenth century, and its solution was therefore a matter of historical interest.

The lecturer then discussed the methods of building operations as disclosed by the accounts of the royal buildings. The King gave his personal instructions to his valet-de-chambre or some important court official, and it was their business to see that contracts were drawn up and the building erected in accordance with those instructions. Full specifications were drawn up, but no architect is referred to till late in the reign of Francis I., and until the appointment of Serlio in 1541 the whole direction and control of the work was in the hands of a layman. The result of this want of competent control is seen in the buildings of the reign of Francis I.

The master builders were struggling blindly with details which they did not understand, and though they possessed considerable traditional knowledge of building processes, their knowledge was, as De l'Orme pointed out, a mere hand-to-mouth affair, and resulted in such disasters as the collapse of Beauvais. As to the guilds, their members seem to have been much more concerned about keeping the market for themselves than about mutual improvement and instruction in the art of building.

Very little, in fact, was known about the Chambiges, the Le Bretons and the master builders whom the enthusiasm of the French writers had exalted to the position of first-rate artists. This view was not borne out either by documentary evidence or by the buildings; though the latter (owing to the happy accidents of outline) were often picturesque, they had no pretensions to serious architectural design. On the other hand, there emerged from the evidence the interesting fact of the existence of a well-defined class of building contractor, with whom the business was hereditary.

The lecturer then dealt with men of the type of Bachelier and Hector Sohier, the builder of the choir of St. Pierre at Caen. He pointed out that here again, though there was abundance of ornament, there was an entire absence of the architectural sense, and that Sohier's work was typical of what fifty years ago was most popular, but in his opinion the least to be admired in the whole range of serious architecture.

The evidence was on the whole conclusive that till the appearance of Philibert De l'Orme, an architect—i.e. the man who from the first had devoted himself to the theory and practice of the art of building—did not exist in France. The buildings of that period owed their attractiveness to happy chance, to their historic associations, to their placing on the banks of the most beautiful river in Europe; but students should be on their guard against treating them as the last words of a consummate art. They were, on the contrary, the half-articulate efforts of beginners striving to explain themselves in an unfamiliar language.

In his third lecture Professor Blomfield, after calling attention to the effect on French culture of the Italian expeditions described the building of Gaillon for Cardinal Georges d'Amboise. He pointed out that the Cardinal believed he was building an Italian palace, but what he really got was a late Gothic house peppered about with Italian Renaissance detail. A comparison of the Amboise monument with the monument to Louis de Brize, in the cathedral at Rouen, showed that the influence of the Renaissance so far was merely superficial. French artists had not yet learnt the cool reticence which marked the best Italian work. Perhaps the most mature example of the architecture of this time (about 1520) was Azay-le-Rideau.

The man who contributed most to the establishment of the new manner in France was Francis I. himself. Building was with him a positive mania, though he never finished his buildings, and if anyone told him a building was in good order he replied that in that case it could not be one of his. His first great enterprise was the north wing of the Chateau of Blois, a building much restored and much misunderstood. Though this building was labelled Renaissance, it was in fact built by the French masons on traditional lines, imperfectly concealed by Italian ornament.

There was no foundation whatever for the legend that the famous staircase was designed by Leonardo da Vinci. It was simply the mediæval newel staircase dressed out with Renaissance details. To the west of this wing lies the block designed by François Mansard, which it was the fashion to deride. Yet it would be impossible to find a better object-lesson in the difference between the ordered dignity of the trained mind and the restless self-assertion of the tradesman.

The King's next undertaking was Fontainebleau. The lecturer described this in detail, pointing out the importance of the work of the Italian artists in relation to the decorative arts of France. Next came the palace of St. Germain, the hunting boxes of La Muette and Chartrès and the country house or hunting lodge of Villers Cotterèts, all the result of the king's passion for hunting, his craving for excitement. Meanwhile Chambord, begun in 1509, was on the whole the greatest of the King's enterprises. Ten years later he began the Château de Madrid in the Bois de Boulogne. A great block of a building lavishly decorated with glazed terra-cotta by Jérôme de la Control was conspicuous, and the result was what was to be expected from a princely amateur with considerable knowledge of ornament, and no one to keep him straight but the actual workmen. The fate of Francis I.'s buildings had been disastrous. St. Germain, restored out of interest, is a museum; Villers Cotterèts is a workhouse; La Muette and the Château de Madrid are utterly destroyed. Noble owners have been as indifferent as the Revolutionaries. And the great buildings that have survived the pick-axe and the fire have now to face the danger of being classed as historical monuments and being thoroughly "restored." On the whole the methods of the Revolutionaries were the least objectionable.

At a Meeting of the Aberdeen district of the Amalgamated Society of Carpenters and Joiners, held last week, a copy of agreement was submitted showing the conditions on which men had accepted employment in the City Colony Elevator workshop, under the Salvation Army's Men's Social Work Scheme. Those who receive employment must, it was stated, be unable to find work otherwise, or must be homeless or friendless. By the rules and regulations enforced in connection with the colony, the men must abstain from all intoxicating drink, must refrain from the use of bad language, must agree to a thorough cleansing of the body on entrance, must expect no payment of any kind beyond food and lodgings, and must recognise that any voluntary payments might be withdrawn at any time. The worker is entitled to have the clothes he brought into the colony returned to him on leaving, but is liable to instant dismissal and forfeiture of any reward promised for industrious work in the case of misdemeanour. The meeting considered the conditions harsh, and did not approve of them, expressing the opinion that no support to the scheme ought to be given from Aberdeen joiners.

The Water Committee of Glasgow Corporation at their meeting on Monday had under consideration the tenders which had been sent in for the construction of the embankment, discharge culvert, and other works in connection with the raising of the levels at Loch Arklet. There were twenty-two tenders. The sub-committee which was specially appointed to consider these, recommended the acceptance of the offer of Messrs. Charles Brand & Son, 188 West Regent Street, Glasgow, amounting to 100,651*l.* 0*s.* 11*d.* The next lowest tenders were 102,494*l.* 1*s.* 6*d.* and 106,008*l.* 14*s.* The water committee unanimously recommended the Corporation to accept Messrs. Brand's offer.

NOTES AND COMMENTS.

ARCHITECTS have scarcely grasped the capabilities of mild steel in building when we are confronted with a new discovery by Messrs. JONAS & COLVER, of the Continental Works, Sheffield. Though this relates more particularly to the manufacture of machinery by the provision of a new high-speed steel, stated to possess six to seven times the cutting power of existing steel of a similar type, it is probably not without its influence on the future of building and architecture. The existence of high-powered cutting tools at once suggests the possibility of a more extended use of granite and other hard building stones, and a differentiation of the suitable and logical artistic treatment of such material. Then, too, we may no longer be restricted to the product of the rolling mill for the form of our girders, joists, and other components of our structural steel work, and it may be possible to evolve a steel architectural treatment that will not tempt us to cover up the barbaric nakedness of our ironwork with scagliola. The cost of turnery in metals should certainly be reduced, and it will no longer be necessary for us when we are designing wrought-iron work after the manner of the Spanish "rejas," to specify that our circular balusters, in order to make them financially possible, are to be in malleable iron. As hardness without brittleness seems to be the predominant characteristic of the new steel, we may expect that some day the scientific enterprise of our manufacturers will give us a steel for stanchions that will combine the great strength in compression of high carbon steel with the toughness and freedom from brittleness that now induce us to prefer mild steel for bearing members.

AMONG the cities that border the eastern seacoast of the United States, and contain the best examples of the "Colonial" style, Salem is one of the most interesting, its prosperity in the commercial marine business of the seventeenth and eighteenth centuries having provided the means for the employment of a quite remarkable group of excellent carvers and workers in wood. Most of their work is found in the interiors, but occasionally, as in our own eighteenth century work, richly worked porches and doorways of wood frame the entrance to otherwise soberly-treated houses and give a foretaste of the charming artistic skill displayed within.

THE success of the first Letchworth exhibition has produced a rush of imitators, but the experience of Newcastle, in the North of England Cottage Exhibition, at Walker, is calculated to give pause to the movement. The chairman, Sir WALTER PLUMMER, and the organising secretary, Mr. ALDRIDGE, at the meeting of the committee held last Saturday endeavoured to minimise the lack of success, and to urge that, in spite of the unfortunate financial result, necessitating a call of fifteen shillings in the pound on the guarantors, the citizens of Newcastle would ultimately benefit by the development of building on municipal lands and the improvement in the character of cottages that should be credited to the incentive of the Cottage Exhibition.

THE depletion of forest lands throughout the world, even in America and Australia, arousing, as it does, the fear that the shortage of supply which we are already feeling may ere long develop into actual famine, has before now suggested that we may be driven to use reinforced concrete for many parts of buildings for which we now employ timber. It is interesting, therefore, to read in this month's issue of *The Royal Engineers' Journal* an account by Major A. H. D. RIACH, R.E., of the manner in which, following the lead of Major STOKES-ROBERTS, R.E., in the barracks at Jubbulpore, reinforced concrete has been adopted in the construction of verandahs for the barracks at Ahmednagar for many parts that ordinarily are made of timber. Major STOKES-ROBERTS and Major RIACH are to be congratulated on their bold experiment and on the success they have achieved, as, in addition to the undoubted advantages in respect of durability and cost of maintenance that reinforced concrete possesses over timber, they have shown that under the conditions obtaining in India the initial cost of the work has been considerably reduced. Put shortly, while the cost of teak is 3.75 rupees per cubic foot, that of reinforced concrete for lintels, posts, &c., is 2 rupees per cubic foot. Part of this saving is due to the cheapness of labour, as the proportion of the cost of this item to that of material is as 1 : 2, and the result would scarcely work out the same here, as we cannot get coolie labour for a quarter rupee a day. On the other hand, material costs rather more in India than in England. As a considerable item is the expense of moulds, for all the members in concrete are cast and seasoned before fixing, economy largely depends on repetition of the same forms, and in a piece of work like a verandah this is possible.

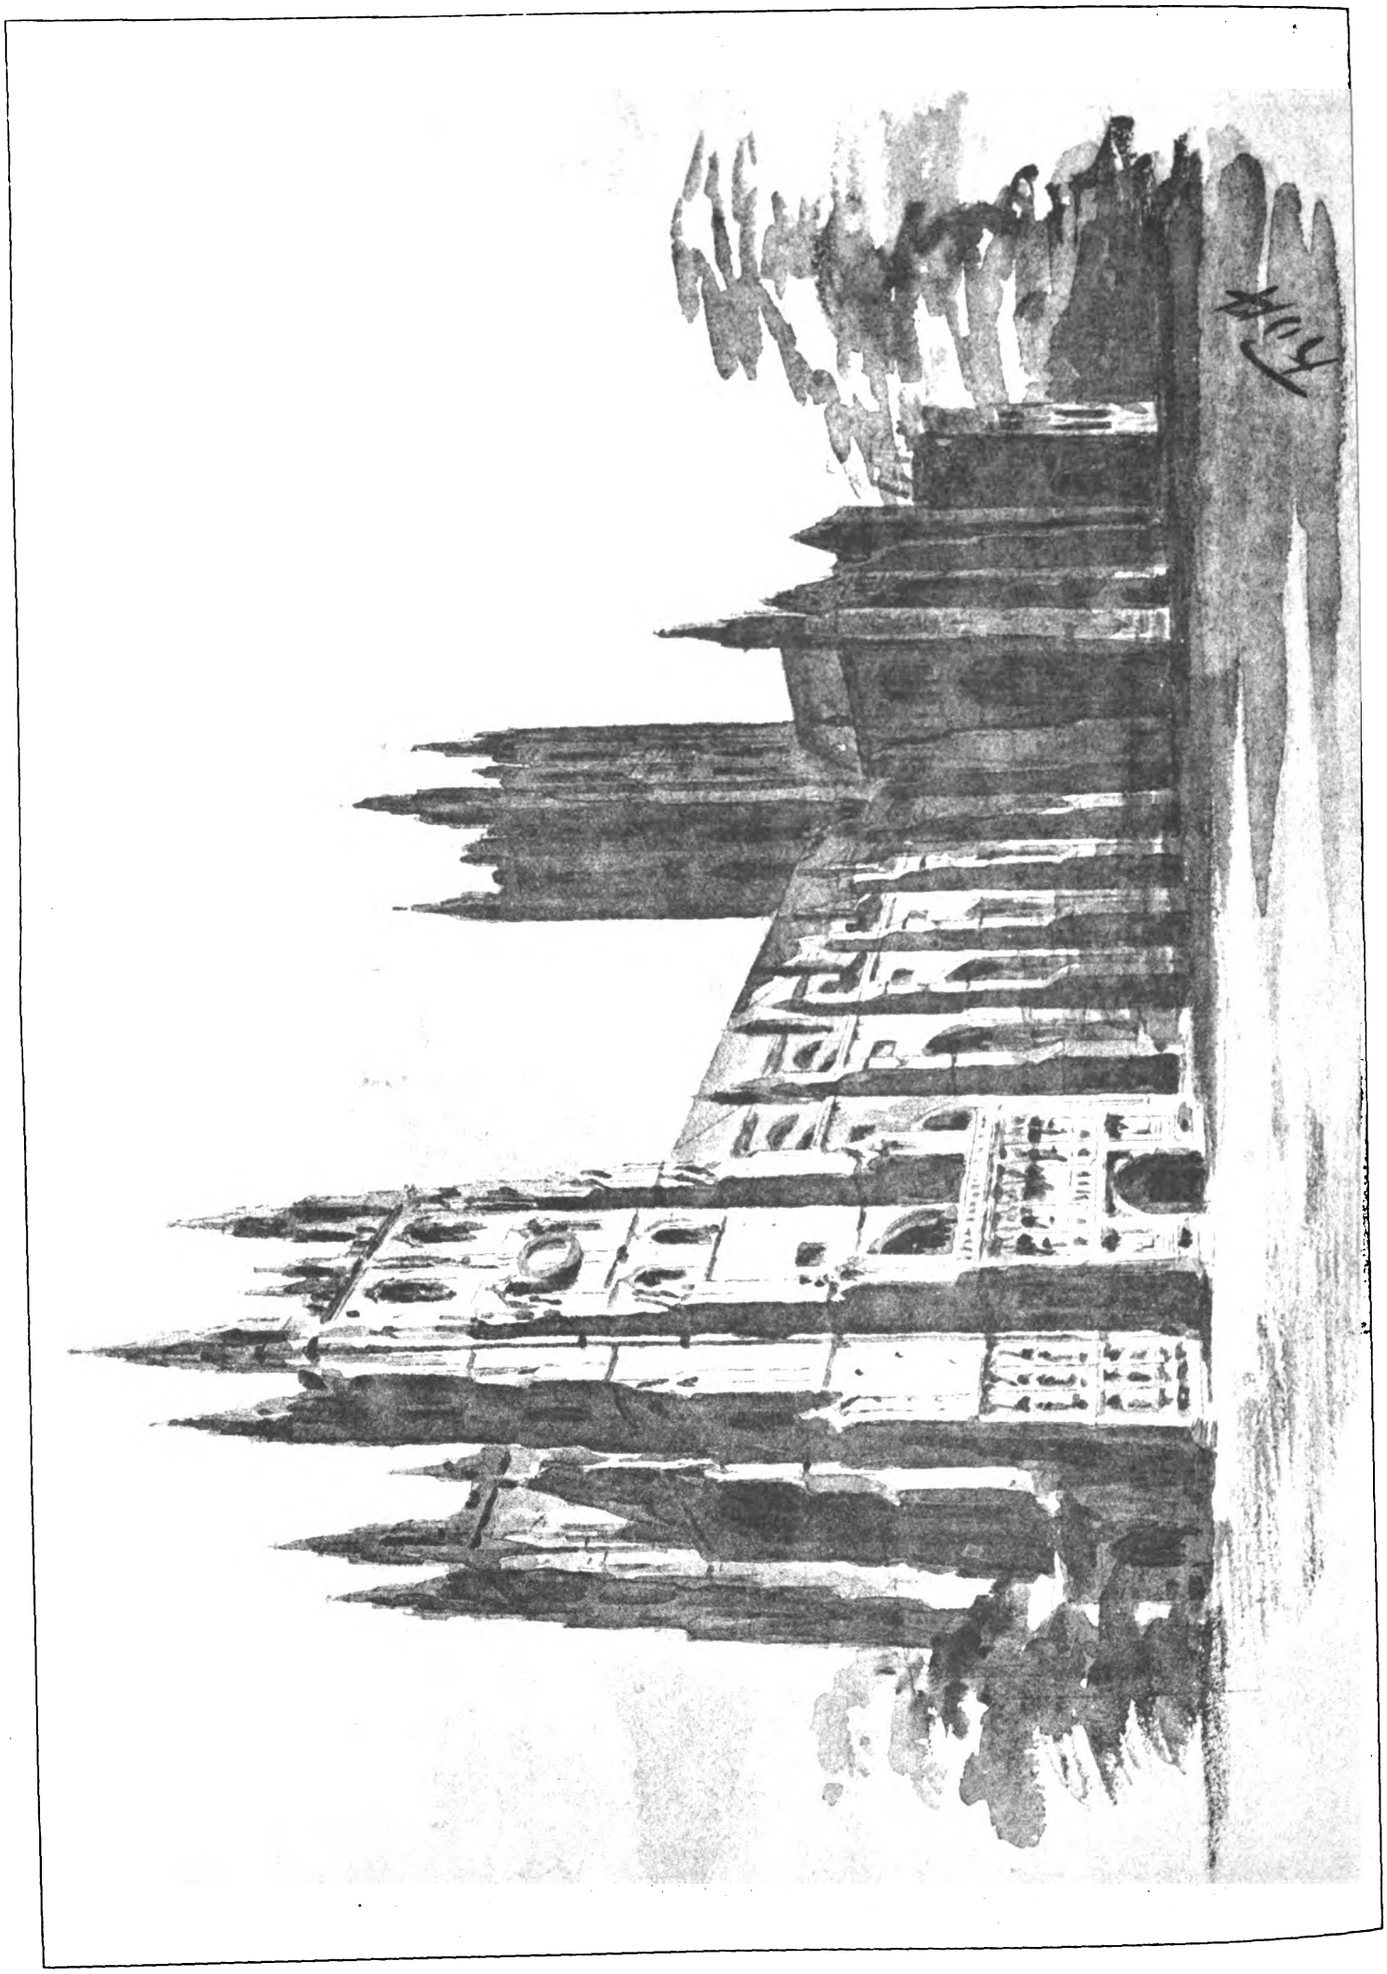
ST. HILDA'S MISSION ROOM, WARLEY.

THE building was erected about two years ago, and forms part of a scheme for a school, church, and vicarage. The portion now erected will be used as a school in the future (when the church is erected), and classrooms will be added on the sides as shown on plan. Thin

Black Country bricks have been used for facings, pointed in white mortar, and the roof covered with hand-made tiles. Walls internally are plastered, and the joinery is deal painted. The work was executed by Mr. T. A. SMITH, builder, Moseley; and the architects were Messrs. BUCKLAND & HAYWOOD-FARMER, Birmingham.

NEW PREMISES, PALL MALL, S.W.

THIS imposing building, 59-60 Pall Mall, has been erected for the London and Lancashire Fire Insurance Office. Mr. E. GUY DAWBER, the architect, had, in preparing his design, to allow of a public passage, known as Crown Court, to cut through his ground floor. The building is faced with Portland stone, and the roof is of green-glazed Normandy tiles. The upper floors are let as bachelors' chambers. The builder was Mr. JAMES CARMICHAEL, of Wandsworth.



ST. ANDREW'S CHURCH, BOSCOMBE.

ST. ANDREW'S CHURCH, Boscombe, is built on a corner site, roads being on the west and north boundaries. The walling for external facing is of Devonshire limestone, finished with a fairly smooth axed face; the dressings, quoins, &c., are of Doulting stone. The same stone is employed internally, the walls being plastered, and roofs of pitch pine, left perfectly plain, and covered externally with red sand-faced tiles. The plan consists of a fairly wide nave, with north and south aisles. There is no chancel arch, the line between nave and chancel being marked with oak screens, which are carried across the aisles. There are similar screens at the back of the oak choir-stalls on either side. The north choir aisle forms a chapel, while the organ is placed in the south choir aisle. The priests' and choir vestries are at the east end of south choir aisle. Messrs. TRASK & SONS, of Norton, were the general contractors, and Messrs. BOULTON & SONS, of Cheltenham, made the choir-stalls and screens. The architects were Messrs. J. OLDRID SCOTT & SON, 2 Dean's Yard, Westminster, S.W.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

The HON. SECRETARY announced the third spring visit was arranged for February 13 to the Holborn town hall, by permission of the architects, Messrs. Warwick & Hall, and also to the new premises of the British Medical Association, by permission of the architect, Mr. H. Percy Adams.

Mr. C. O. Hooper was duly elected a member.

Mr. H. T. BUCKLAND read a paper, illustrated by lantern views, on—

Schools.

In venturing to address you on a subject upon which so many are better qualified to speak than myself, I fear I cannot hope to add much that is new to what has already been said upon a class of building so governed by rules and regulations with regard to planning that any very great departure from existing models would be well-nigh impossible until a new curriculum provides a necessity for a different environment; neither would it be possible in an evening to attempt any serious account of the history and development of school buildings in England and other countries; but as it is always of interest to hear how problems of planning and detail have presented themselves to and been dealt with by others, I shall venture to draw your attention to some of the points which have particularly exercised my own mind in the planning and design of public elementary and secondary schools in a large town, illustrating my remarks by examples of recent school plans (kindly placed at my disposal by various architects) and some of my own.

Before attempting any illustration of plans of school buildings it will perhaps be well to consider the curriculum of the Council schools of this country as ordained by the Board of Education.

The elementary schools take children from the age of five; they may be taken younger, but the Board has recently discouraged the entrance of children under that age. From the ages of five to seven years children go into the infants' department, and from the latter age into the upper departments. In the upper departments there are seven standards, the lowest being number one; when children have passed standard five they are eligible for a secondary school, providing they can pass the entrance examination. In an elementary school children may be kept until the age of fifteen, after that no grant will be paid; and in secondary schools until the age of eighteen, after that age the same remark applies. In an elementary school the usual hours are from 9 till 12 and 2 to 4.30, with no school on Saturdays. The subjects taught are reading, writing, arithmetic, a little algebra, English history, geography, elementary physics and chemistry, singing, drawing, manual training and physical exercises. Latin and French are taken as exceptional subjects in a few schools.

At nine in the morning the various departments assemble in the hall for the Lord's Prayer and the singing of a hymn, and then dismiss to their class-rooms.

The above curriculum for an elementary school is, I believe, a fairly general one. I understand that in secondary schools very much greater licence is now permitted in the arrangement of a curriculum than was formerly the case, so that the one I am about to outline must not be taken as exactly typical, although it appears a very good one. The following is a list of the subjects taught:—Mathematics, comprising arithmetic, algebra and trigonometry; English; French; Latin; German; geography; history; singing; science; drawing; handicrafts (working in wood and iron); gymnastics. Of these, out of a working week of twenty-five hours and twenty-five minutes, drawing absorbs one hour and a third; handicraft, two hours; science, four hours and a half; and gymnastics, one hour and a half. These times are given as averages, as they vary in the different classes. In science, for instance, in the lowest forms one hour and three-quarters only are devoted to this subject, while in the highest it runs up to seven hours. In this particular school there are five forms, of which the sixth is the highest and the second or preparatory class the lowest; some of these forms are divided into upper and lower, and some of them into upper, middle and lower. The school assembles in the hall at 9 for hymns, prayers and a short reading from the Scriptures before dispersing to classes. The hours are from 9 to 12.30 and from 2 to 4.30. There is a half-holiday on Wednesdays and a whole one on Saturdays.

I have ventured to go into these details because it seems essential to have a clear idea with regard to the uses of a building before proceeding to discuss the kind of accommodation which should be provided to afford the maximum amount of convenience for them. In the daily time-table of both the elementary and the secondary school it will be observed that there is an assembly each morning before dismissal to class-work; this gives rise to one of the important differences between the plans of schools in this country and those of America and the Continent, viz. the relation of the assembly hall to the rest of the building. In the majority of our schools this occupies an important position, due mainly to its frequent use; in America and on the Continent it is usually placed on an upper floor and comparatively out of the way, owing to the fact that a daily assembly is not the rule, as the children enter the school and go straight to their class-rooms. For this reason we find many of these schools planned with a cloak-room in connection with each class-room.

The rules of the Board of Education to be observed in the planning and fitting up of public, elementary and secondary schools of necessity influence all planning so considerably that it is not possible for me to proceed very far without a reference to them, as they are the guide to which all authorities (upon whom the burden of providing school accommodation rests) are compelled to defer when arranging for the erection of a new building; rather, however, than discuss them seriatim I should prefer to consider their practical application. Let me assume for a moment that an education authority in a large town has to erect a new school and is about to instruct an architect to prepare plans. What are the points upon which the latter will need to be informed? (1) The number of children to be accommodated; (2) in what number of departments the school is to be planned; (3) is the building to be planned on one or more floors; (4) what numbers are to be accommodated in each of the class-rooms.

I have assumed a site has already been chosen, as in large towns sites have frequently to be purchased long before a school is required, so that in many cases the architect who is eventually employed to erect the schools cannot be consulted. Where, however, this is possible, it should certainly be done, as the question of aspect is an extremely important one. We have, many of us, I dare say, been faced with the problem of planning a school to go on a long narrow site, with its short axis north and south, and an absolute instruction to get the majority of the class-rooms on the south side—no easy matter if the school is to have central halls and the length of the site is comparatively limited. It is true in a large town that one is not able always to choose a site with the best aspect, for the simple reason that there is not one to be had; in that case obviously any instructions with regard to the aspect of class-rooms should be very general in character.

I will now return to the points upon which I suggested an architect would need to be informed before commencing to plan a school and consider them in the light of the Board of Education's requirements. Dealing first with elementary schools, my first two points together—number to be accommodated and in what number of departments. What does our guide say? "No school should ordinarily be built to accommodate more than 1,000 to 1,200 children in three departments. No single department should accommodate more than 400 children. A large school in three departments might conveniently be divided in the following proportions:—Boys, 360; girls, 360; infants, 380." It goes on to say:—"In departments of this size the most suitable plan is that of a central hall, with the class-rooms grouped round it." Now it is obvious from this instruction that a school with three departments if planned as suggested must have three central halls, unless advantage is taken of a further instruction, which says:—"A single central hall may be provided for the joint use at separate times of two departments, provided that it is so placed as to be readily accessible from the class-rooms of each department." There may be many examples of schools where this condition has been taken advantage of. The only one I am personally acquainted with is at Darlaston. In this school one hall is used for three departments. Now, although a three-department school may be the most efficient, it is also the most expensive both to build and to maintain, as a headmaster and two headmistresses have to be employed. Either this fact or a preference for a mixed school has led to the building of schools in two departments instead of three—viz. an infants' and a mixed department—whether with a view to economy or the preference already suggested I am unable to say. If the latter, the plea is certainly justified by the Continental and the American practice, as mixed departments are the almost invariable rule both in America and on the Con-

Digitized by Google

tinent. And in Great Britain it may be said that as we go further north the mixed school gets more common and in Scotland is almost universal.

The next question upon which we have to seek enlightenment is whether the building is to be planned upon one or more floors. Upon this point our guide says:—"Where the site is sufficiently large, open and fairly level, the most economical plan is that of a school on a single floor. Such an arrangement is also preferable on educational grounds. In any case it is desirable that a school building should not be on more than two floors. A building on three floors is open to many objections, and should only be proposed in special circumstances or on very costly sites." This recommendation has, I think, been very widely adopted throughout the country; and in Birmingham no elementary school has for many years been erected with more than one floor.

Then as to the numbers to be accommodated in each of the class-rooms, after suggesting the sizes of the departments—boys, 360; girls, 360; infants, 380—the Rules go on to say:—"As a rule, such a department would probably require seven class-rooms." This would give us six for fifty each, and one for sixty, in each of the upper departments; and four for fifty, and three for sixty, in the infants' department.

Education authorities and head teachers in elementary schools are, I believe, fairly generally agreed that a class of fifty children is all a teacher can efficiently teach. The need for class-rooms accommodating sixty is chiefly to provide for the classes at the beginning of the educational year, as they are always larger then than at any other time, and only gradually drop to the average.

These, then, are the main points to which consideration must first be given in the planning of all elementary school buildings. I think there can be no question that a central hall is undoubtedly the best for an elementary school, as it affords excellent means of supervision and convenient access to class-rooms, and although schools have been recently built with an enlarged corridor which might almost be called a central hall, the examples I propose to show all have the marked characteristics of a genuine hall.

Different education authorities have different views with regard to the erection of a three-department school on one floor. We shall find some prefer all the departments in one block, others in two blocks (the infants' department being the one usually kept separate), and in some cases a preference appears to exist for each department in a separate block.

The *pros* and *cons* may be briefly summed up as follows:—A building in one block is more economical to erect; can be heated from one centre, and is consequently cheaper to maintain. In two blocks slightly better lighting and probably better disposition of playgrounds are possible, and one central hall may be side-lighted. In three blocks the same remarks apply, and side-lighted central halls become possible in all departments, and a natural system of ventilation is facilitated.

Special conditions as to site and other circumstances give rise to infinite variety in particular cases, but with such I do not propose to deal, so will proceed to a consideration of secondary schools. Government aid for secondary education has only been available since the passing of the Act of 1902; until that time the higher grade school was the only continuation of State-aided general education, and the buildings provided for this higher grade education were modelled upon those for elementary education; it is, therefore, not surprising to find that the earlier secondary schools erected after the passing of the Act of 1902 bear all the marked characteristics of the elementary school in their planning.

The central hall still holds its own, and the Board of Education appears to regard it as the best type of plan, as witness a general note in "Principles to be Observed in Designing and Fitting-up New Buildings for Use as Secondary Schools," which reads as follows:—"The rooms should be grouped compactly and conveniently in order to secure easy and effective supervision and economy in working and maintenance. Generally speaking, in the case of schools where the number of scholars is considerable, this result can most satisfactorily be secured by placing the class-rooms on three sides of and opening from a central hall."

Differences of opinion upon secondary school planning will, I think, be found mainly on this question, and a marked tendency may be perceived to provide a hall which is not a passage-room to and from the various class-rooms, corridors, &c. Such an arrangement affords a room not only for general assembly, but one which may also be used (free from interruption) for various purposes, such as examinations, singing, drawing (if there is no art room), and any assembly of a portion of the school without disturbing the remainder, for any of which purposes a central hall is not so convenient. On the other hand, a central hall is, before all things, adapted for good supervision, but is this of extreme importance in a school with an adequate and thoroughly qualified staff? Expressions of opinion from head masters and mistresses certainly incline me to think not. If, then, a hall is required to be used for all or any of the purposes I have just mentioned, a central hall does not appear to be the best arrangement which could be adopted; if, on the other hand, supervision of teachers and students is of paramount importance, then the claims of the central-hall plan cannot be disputed. The Board of Education, as I have already pointed out, is very definite upon this question, and in addition to the clause I have already quoted goes on to say:—"Where more than one floor is necessary, the upper rooms can be entered from a gallery which should be in full view of the hall."

I know of elementary schools planned upon these lines which have been found noisy and inconvenient; possibly the better discipline of a secondary school would prevent the former; if so, might it not also insure satisfactory behaviour without such elaborate provision for supervision? Fortunately, the Board of Education, while offering guidance, do not insist upon an abject submission to such guidance, and express their willingness to consider other suggestions in the following words:—"The Board recognise that, owing to the wide difference between the various grades and kinds of secondary schools, and pupil teachers' centres, it is undesirable to attempt to lay down any hard and fast rules as to the actual method of planning to be adopted except on points of fundamental importance." I think it will be generally admitted that the best interests of all concerned are likely to be ensured by a course which affords opportunities for the expression of differences of opinion in the planning of school buildings. Many examples of recent secondary schools certainly show evidence that all are not agreed upon the point under discussion.

As in the case of elementary schools, I will now proceed to discuss the points upon which an architect will need to be informed in planning a secondary school.

1. With regard to the number of children to be accommodated, the Board of Education makes no suggestion on this point; personally I know of no recent secondary school which accommodates more than 430 scholars in one department, and from 200 to 300 appears to be a very usual number.

2. In what number of departments is a school to be planned? As infants have no longer to be considered (except that a Kindergarten is sometimes provided in connection with a girls' school), only two remain. Curiously enough, the Board of Education offers no guidance as to whether a school shall be in two departments—a mixed school or entirely independent for boys and girls. As both are being built, there seems no doubt either that differences of opinion exist or that motives of economy have probably borne their share in a decision, as in the case of elementary schools.

An arrangement which appears to be a sensible one on both educational and economical grounds (at any rate so far as the cost of buildings is concerned) is to plan a school for boys and girls with hall and class-rooms separate for each, but with certain rooms for special instruction—such as chemical laboratories, lecture rooms, art rooms, gymnasium, &c., in common. It will be found that a time-table can be arranged which will permit of these rooms being used in turn by boys and girls, and economy is effected by not having to provide them in duplicate. The merits of "mixed" or "not mixed" education in secondary schools I think we may conveniently leave to educationalists to settle.

3. Upon the question of the number to be accommodated in the various class-rooms we find very clear instructions in the Board of Education Rules:—"In every school there must be class-rooms at the rate of four for every 100 scholars. There must be in the class-rooms, as distinct from the laboratories and other rooms, sufficient accommodation for the whole number of the scholars for whom the school is intended to provide. A lecture-room, however, if suitable for class teaching, may be counted as a class-room for not more than thirty or less than fifteen scholars. Class-rooms should be fitted with single desks, having a gangway of not less than 18 inches between the rows and between the desks and wall on each side, 1 foot between the last row of desks and the wall, and a clear space extending the full width of the room of not less than 7 feet 6 inches between the front row of desks and the wall for the teacher. The desks may be reckoned as occupying a space of about 3 feet by 2 feet in

Digitized by Google

order to provide the requisite distance between the front of one and the back of that next in front of it.

"To provide for this a floor area of from 17 square feet to 18 square feet per head will be required, according to the size of the class. In cases where it is found difficult to provide this amount the Board will be prepared to accept a minimum allowance of 16 square feet per head, provided that the arrangement can be shown to be satisfactory. In this case the desks should be placed closer together in pairs, with a gangway of not less than 2 feet between the double rows of desks. Where fireplaces are provided they should be placed in the outer corner of the room, in order to avoid interference with the master's platform and blackboard. Stepped seating should not be used."

Intimately bearing upon this and the total accommodation of a school is an introductory note, which reads as follows:—"It is important to remember that as the actual numbers in a class can seldom be made to correspond closely with the various sizes of rooms provided, the nominal accommodation as shown by the plans should exceed the number for which the school is intended to provide." This means, of course, that as a general rule a school which has nominal accommodation in class-rooms for, say, 225, will only be considered as providing accommodation for, say, 200 children.

The charming inconsistency of the promoters of schools' competitions is very noticeable with regard to this point; invariably the question goes to them as to whether the cost of the building is to be based upon the nominal accommodation shown upon the plans or upon the number for which the school is intended to provide. It is scarcely necessary for me to say that the invariable reply is the latter. Now, if the price allowed per head is 40*l*. (which, by the way, it seldom is and more often should be), the difference amounts to 1,000*l*., and it is entirely absurd to ask for the extra accommodation without expecting to allow for it in the cost.

As to the number of floors, the Rules offer no guidance except in so far as they assume that more than one floor may be necessary in a clause I have already quoted in connection with the question of a central hall. It reads as follows:—"Where more than one floor is necessary the upper rooms can be entered from a gallery," &c. I think there is little doubt that a two-storey building is the most convenient. I am not acquainted with one consisting of a ground floor only, but there are many of more than two storeys. If the desirability of more than one floor is admitted, what then is the best apportionment of the various rooms to the separate floors? Personally I consider it important to have all class-rooms on the same floor as the hall, and this preferably the ground floor. Laboratories, lecture rooms, art studio, &c., all rooms which are occupied by each class in turn for a portion of the day, can be placed conveniently on the upper floor.

The general class-room accommodation in a secondary school is so similar to that of an elementary school that I need not spend time in discussing it, but the following comparative area, as required by the Board of Education, may be of interest:—In assembly rooms of secondary schools at least 6 square feet per scholar, and if the school is for less than 150, 8 square feet. In elementary schools not more than 4 square feet per child is allowed and 3½ square feet is considered sufficient.

In class-rooms of secondary schools 17 square feet or 18 square feet per head is required, while a minimum of 16 square feet may be accepted. In elementary schools 9 square feet is required for infants and 10 square feet for other children. I admit I find these differences somewhat puzzling; the schools are both for the same children (in the one case when they have, some of them, grown older); and the question naturally presents itself, Is the one too large or the other too small? In a small elementary school with a department for only 200, I think the latter, as even on the 4 square feet basis the hall will only be 800 feet in area. Now the children in an elementary school have to use this hall for drill in wet weather, and a space of 40 feet by 20 feet does not afford sufficient accommodation for one class.

If a secondary school has a gymnasium, the assembly hall is not used for drilling; nevertheless, it has twice the area of that in the elementary school.

(To be concluded.)

Mr. W. Giles, deputy town clerk of York, has been awarded an honorarium of 150 guineas by the Corporation for his work in restoring and cataloguing the city's ancient books and documents. The work was done in his own time during ten years.

WOODWORK.

(Concluded from last week.)

ALL through the seventeenth century English carpenters generally followed the traditional details and construction in use for the past 200 years, and the change gradually took place in the introduction of Classic detail, grafted on to the old methods of construction. The timber-fronted house of Sir Paul Pindar, which formerly stood in Bishopsgate Street, and is now in the South Kensington Museum, dates from about the middle of the seventeenth century.

The shape of the central bay window had been in use since the early part of the sixteenth century, but the ornament and the carved panels and details generally are 150 years later.

Few buildings of any importance were built of timber after the end of the seventeenth century, and up to this time they were doubtless designed as well as executed by the same craftsmen.

The treatment of the floors and ceilings of the Middle Ages must not be overlooked, as they formed an integral part of the construction of the buildings.

The floors of the rooms were generally formed of large square beams resting on wooden plates, which also formed the cornice of the rooms.

These joists and beams were frequently moulded and carved, and the spaces between filled in with plaster or wood.

In other cases the undersides of the floor joists were covered with boarding divided by ribs into panels with bosses at the intersections, carved with foliage, coats of arms, or other ornament.

Many of these old ceilings and church roofs bear traces of colouring, and, though dimmed by the hand of time, still bear testimony to the splendour of our old buildings when decorated from floor to ceiling with colour.

We can hardly realise to-day what the effect must have been in the coloured pavements, frescoed walls, the stained-glass windows, in the rood lofts and screens, the lower panels filled with paintings of the Apostles and Saints, in the sepulchral monuments, and finally in the roof itself.

As a rule, in the latter the colour was confined to the mouldings and carvings, and in flat roofs the panels were often painted and sprinkled with gold stars on a blue ground.

Doorways, again, were a frequent subject of decoration, and it was generally here, as in the fireplaces, that the craftsman exhibited most of his skill and power of design.

The earlier examples consist of ledges to which the vertical boards were nailed, a method of construction in use to-day. Very frequently the door was decorated externally with tracery planted on, in imitation of the stonework of the windows.

This was especially the case with the doors in the fifteenth century, when the craft of the smith was so inferior to that of the men who made the wonderful thirteenth-century hinges that there was no longer need to leave room for its display. Later the doors were divided up into small panels with moulded stiles and rails.

Turning to the inside of dwellings in mediæval days, we find the three chief methods of decorating the walls of rooms were by panelling, by hanging with tapestry, and by painting, the last being an imitation of curtains or tapestry hangings, or else painted with subjects of romance and legend.

Probably the earliest wood panelling was of deal imported from Norway; it was generally stained or painted green. A room was made like this at Windsor Castle for Henry III., and there is probably little doubt that till the middle of the seventeenth century much wood and stonework was coloured.

In the long gallery at Chastleton Hall, in Oxfordshire, at Hardwick Hall and at Bolsover Castle, in Derbyshire, the sixteenth-century wainscotting on the walls bears traces of colour and gilding, and numerous examples are to be seen in many houses in England.

The development of wood panelling is interesting, and is typical of the evolution of design in this country, and is dealt with exhaustively by Mr. Gotch in his work on Early Renaissance architecture. Before the sixteenth century it followed the Gothic manner, and was constructed on a substantial scale, the framing being formed of wood uprights and cross-pieces, some 4 inches by 3 inches in section.

The uprights were some 18 inches or 2 feet apart, and the cross-braces perhaps 4 or 5 feet, according to the height of the room.

The spaces between were filled with one piece of board let

Digitized by Google

into the surrounding framework, which was sometimes splayed or moulded.

The panels in Gothic work were ornamented with cusping or tracery, or with paintings.

Gradually the heaviness of the framework was reduced, and the stiles and rails, though remaining the same width, became only an inch or so in thickness.

The panels again were made narrower, as it was easier to get boards 10 inches or 12 inches wide than double that width.

Moulding and splaying the margins of the wood framing was long retained. At first the moulding and splay on the horizontal rails dies out before it reaches the upright stiles; then it is mitred in the solid; and eventually we find it planted on separately, until in later years we have the large bolection mouldings so characteristic of Wren's work in the eighteenth century.

Thus we have the extension of panelling until it covered the whole walls of rooms and it became universal, and only died out when wallpapering came into fashion.

Just as at first in the so-called Gothic times we find the upper portions of the panels filled with tracery, so we see afterwards how this developed into the carved panels of Henry VIII.'s and Elizabeth's time, with heads surrounded by ornament, Italian in design and feeling.

Then we have the thoroughly English treatment of the linen panels, the decoration being something like a folded napkin laid on the panel.

In the panelling from Haddon Hall we notice the small moulding to the panels mitred all round out of the solid—mason's mitres—but this was difficult in that it required great accuracy in setting out and working to get the mitres to fit exactly, though by the end of the sixteenth century this treatment had entirely superseded the earlier forms of stopped mouldings. Gradually the panels themselves, at first decorated with tracery, linen patterns or carving, became plainer and simpler, and the ornament was confined to the frieze or upper panels.

The monotony of the repetition of rows of panels was broken up by the introduction of pilasters, on which most of the ornament was now lavished. They were either fluted or worked with patterns.

All this panelling formed the actual decoration of the rooms themselves and took the place of tapestry, and each room was a complete design in itself, and the intention was to convey a sense of continuous covering to the walls.

Sometimes the panels were filled with semi-circular arches, carried on pilasters with caps and bases, a treatment frequently met with in the oak chests of the period.

The long gallery at Haddon Hall has these in wide and narrow widths alternately.

Occasionally instead of carving the actual wood itself the projection was got by cutting the ornament out of another piece of wood and planting it on the surface, a method met with in Elizabethan and Jacobean work, as also the multiplicity of mitred mouldings, often covering the whole surface of the panels. Indeed, to specify even briefly the various treatments and designs in panelling at this period—the close of the sixteenth century and beginning of the seventeenth—would be impossible in our limited time.

England up to this period still retained the Romantic spirit of the Middle Ages, and was the home of Gothic architecture, just as Italy was the home of Classic architecture.

The first indication of the Renaissance or Classical feeling in the design of woodwork in this country dates from the commencement of the sixteenth century, in Henry VIII.'s reign; and the first important work in decoration by Italian workmen was at Hampton Court Palace by Wolsey in 1515, and in the tomb of Henry VII. in Westminster Abbey. The influence of these men was productive of much graceful carving and delicate detail, but the style was too severe for the English craftsmen to handle, and it was eventually through the medium of the Low Countries that it became grafted in this country later in the century.

Classical architecture was the mainspring of the design, whether it came from Italy direct or through the coarser channels of Germany and Flanders.

The beautiful panelling now in South Kensington Museum from Exeter clearly shows the evidence of Italian influence, if indeed it is not actually imported work; and whether it was the fact that the Italians are said to have favoured the South Coast, it is certain that we meet with much refined and delicate work in that part of England.

Perhaps the finest example of woodwork in this country, if not in Northern Europe, is the screen in King's College Chapel, Cambridge.

Mr. Gotch says it may safely be dated between 1532-6, as the arms and badges of Henry VIII. and Anne Boleyn are on it. It is thoroughly Italian in design, treatment and detail, and, although we have no record of the makers, it is so obviously foreign in character that there is no doubt on this point. Like the work of the Italians at Hampton Court and elsewhere, it is an isolated example and had but small influence on the English craftsmen at the time, and until the end of the sixteenth century the Gothic tradition still lingered on in this country, and for many years it was only in such small objects as tombs, screens, chantries and the minor details of larger buildings that the new style showed itself.

After the Italian influence died out the Flemings favoured the East Coast, and at first we find a mixture of crude Classic detail and grotesque ornament, applied without knowledge or much skill, yet at the same time possessing remarkably picturesque effects and a certain rough originality.

Some of the finest specimens of this essentially English type of work are to be found in the halls of the colleges and of our large houses.

As you know, the hall had been for many years the central feature of the house, and the entrance was generally into a space divided on one side from the hall by a screen, and communicating with the domestic offices on the other.

The hall was entirely panelled and the screen even more richly decorated, its doorways flanked with columns which carried an entablature, above which was the panelled front of the gallery, surmounted by a series of arches or crowned with the fantastic strap-work peculiar to the time; the spaces between the columns were panelled, and every panel again was filled with carving, coats of arms, or allegorical subjects.

Knole House in Kent, and Wadham College at Oxford, are examples of more or less simple designs, but the hall at Middle Temple and Trinity College, Cambridge, show this treatment in its grandest conception.

The walls above the panelling were hung with tapestry, or with modelled plaster-work, or left plain for the display of arms or even pictures, which by this time were much in fashion.

The roofs, until the general use of plaster ceilings, were still almost Gothic in form and construction, though the detail was Classic in character. The roof of the Great Hall at Hampton Court, built by Henry VIII., shows this very clearly; for whilst it is essentially late Gothic in construction, yet the pendants are composed of Renaissance detail, based on Italian models, and are almost identical with those to the screen at King's College, Cambridge, which was being done at the same time.

The doors, chimney-pieces and monuments, as in earlier times, were objects of very lavish treatment, and much elaboration was bestowed upon them, the chimney-pieces especially, and whether in wood or stone were generally treated in the same manner.

The fireplace opening was flanked on either side with columns or pilasters carrying an entablature of architrave, frieze and cornice; above this was another order of the same kind, and the space between filled with the coats of arms of the owner or carvings of arabesques.

Frequently the upper part was divided by arches and smaller pilasters freely treated with carving and ornament; but, while in keeping with the general panelling of the room, the chimney-piece as a rule was always made the chief feature.

There are elaborate examples at Cobham, Blickling, the Charterhouse, &c.

The one now in South Kensington Museum from Bromley-by-Bow, about 1603, is a remarkably fine specimen, and well worth studying as typical of the period.

The commencement of the seventeenth century, or even earlier, saw the last of the rich open roofs and wooden-beamed ceilings of mediæval days, and plaster ones took their place.

For many years these were based upon the flat-boarded ceilings of the late Gothic joiners, with moulded wood ribs and bosses at the intersections.

The wood ribs were now replaced by plaster, and as this material, being plastic, allowed freer handling, they gradually developed into ribands and strap-work, spirals and scrolls, and all the multifarious forms we find in the ceilings of old houses.

But this, though bound up with the decorative treatment of the panelled rooms, hardly comes within our scope to-night.

Gradually, as the seventeenth century progressed, the German influence died out, and the wild exuberance of the Elizabethan craftsmen and designers merged into a more refined and dignified style, of better proportion and less lavish display of ornament.

With Inigo Jones came a broader and more scholarly knowledge of Italian architecture and detail, and though based almost entirely on Classical influences, yet the woodwork of this period retained a character essentially English and soon lost any traces of foreign influence.

The workmanship was of the best, the construction admirable and the design well suited to its purposes.

It is, in a brief paper, only possible to touch upon the influences that gradually changed the styles of woodwork in England, but broadly speaking they followed the contemporary architecture of the time and indeed formed part of it.

Towards the close of the seventeenth century Sir Christopher Wren had been for some years rebuilding London after the Great Fire, and he had gradually gathered around him a school of craftsmen and carvers, whose influence upon the work of the country was far reaching. It was indeed an age of constructive joinery and beautiful carving, and whether in oak or in deal one single style and tradition permeated the whole country.

Fortunately we are particularly rich in examples of this peculiarly English work, and in our City churches, country and town houses we can examine its construction and admire the knowledge and skill in its design.

The panelling and woodwork of Inigo Jones and Wren was designed from a different standpoint to that of the preceding centuries, and its arrangement formed part of the architectural scheme of the whole building, not of the individual room only.

In Wren's beautiful work at Hampton Court and in many of our City churches we can see how admirably this was done and how greatly this class of woodwork had gained in breadth of treatment and quality of design.

As instancing the enormous change in the spirit and design of woodwork that had come over the country in the space of some 300 years, we may compare the choir stalls of one of the Mediæval buildings with those of St. Paul's Cathedral. Both are superb examples of English craftsmanship, yet one is essentially Gothic, breathing the very spirit of religious fervour and mysticism; the other equally beautiful, but inspired by Classical motives and conceived from an entirely different standpoint.

Again, consider the carving of the thirteenth century, full of quaint suggestiveness and realism and interpreting the human feeling of the moment; on the other hand, the carving of Grinling Gibbons and the eighteenth-century school, equally full of vigour and feeling, but conventional in design and treatment.

This type of work continued until the beginning of the nineteenth century, after which, in design and detail, it lost its breadth of treatment and became thin and wiry looking, although the workmanship was still admirable. With the Victorian era the last lingering tradition in design died out and a period of chaos set in. Architecture was perhaps at its lowest ebb, and woodwork followed in its wake.

And this brings us back to one thing worth remembering, that throughout all the years when architecture flourished and was a living art, woodwork was the same and beautiful work was the result; but as soon as there ceased to be any real tradition in architecture, so at the same moment good design and workmanship in woodwork, as in all the other crafts, died out.

The two are inseparable; they always have been and always will be.

Up to the seventeenth century there is no doubt that the bulk of the work was designed, as well as carried out, by the same men. If a roof was required or a door had to be made there was a traditional way of doing it, a way which doubtless varied in different localities and with the skill of the craftsmen employed; but whether the work was in wood, stone or metal, it all formed part of the structure, and was conceived and executed in harmony with the spirit and feeling which dominated the entire building.

And that is one reason for my urging that you should study the noble heritage of beautiful work left us in the old buildings scattered throughout the country, not with any idea of imitation, but to help you to realise this great principle in old craftsmanship.

Do not think because I have dealt with great and noble works that in them only are to be found the best examples of the carpenter's art, for just as frequently you will find admirable instances in the old houses and wayside cottages, but wherever you find them you will see that their interest and charm depends upon the balance and relation of each part to the whole building.

In the previous lectures you have seen illustrations of much good work that is being done to-day, and I am therefore not dealing with that side of the matter, but as I firmly believe we have steadily growing up in this country a real living common-sense style of building and architecture, so also will a marked improvement in woodwork and carpentry grow up with it.

ANOMALIES IN BY-LAWS AND REGULATIONS WHICH AFFECT SANITATION.*

ON the invitation of the Croydon Association of Surveyors it was my privilege to read a paper on this subject at one of their recent monthly meetings. In the discussion which followed I was pleased to note the tone of general approval of the points the paper was designed to illustrate. Since the meeting the context of the paper has been freely circulated in the columns of technical journals which are read by those whose duties and business bring them in touch with the subject in various forms and degrees of interest. The same journals subsequently published letters from correspondents which tend to show that there is a general agreement with the necessity to remove some of the anomalies that are on all sides admitted to exist, and bring into line the principles and practice in the actual work with the fundamental principles which are taught in the technical schools.

In this relation it has been long a source of discouragement to those whose efforts have tended in the direction of increasing the practical value of higher and technical education to appreciate how far the existing conditions were responsible in preventing the full attainment of the objects of this educational movement.

There is, however, reason to hope that the general agreement on this subject will go far in effecting the desired result by enlisting the serious consideration of the points involved by the department of the Government which exercises control in these matters, but at a gathering composed largely of officials who administer laws and regulations formulated and approved by that department, it is unnecessary to point out that the desired reforms can much better and more rapidly be achieved in an upward direction than by commencing at the top as embodied by the department itself.

It is not intended to suggest that nothing has yet been done to bring the matter to the notice of the highest authorities of the Local Government Board. By the privilege of my position as a chief examiner in the department of technical education which includes the subjects which relate to all that affects plumbing and sanitation, under the authority which issues the syllabus, approves teachers, conducts examinations and grants certificates, I was enabled to bring this matter forward on the plea that the variation in local by-laws and regulations, and the errors in fundamental principles many of these contained, tended to weaken, if not oppose, the teaching of the technical classes.

The experience gained in association with municipal work as a sometime member of a young but very progressive Town Council and member of the several committees which administer these by-laws, combined with a long and varied experience as a plumber and the invaluable sources of information the position as President of the Institute of Plumbers placed within reach, all tended to add a little weight in securing in a most courteous manner the interest and consideration it was desirable to enlist.

As the points of the previous paper to which allusion has been made will doubtless have been read by most of those present in one or other of the journals, it will be unnecessary to do more than touch upon the main points it contained, and thus permit of an extension of the subject which goes beyond the sphere of domestic drainage, but is no less concerned with sanitation and by-laws.

The following extract from one of the contributions to the technical Press in support of my object will serve in a concise form as an introduction to the subject.

Anomalies of By-Laws.

The above paper not only deals with the anomalies that appear to be inseparable from local by-laws, but also compre-

* A paper by Mr. William Challoner, president of the Institution of Plumbers, read before the Midland Association of Local Government Officials on February 8.

Digitized by Google

hensively covers the important omissions and ambiguous commissions as evidenced by the sanitary and building by-laws of most local authorities. No one who has had any practical experience of their total inadequacy for present requirements will have the slightest doubt that there is urgent need for revision, modernising, and unification of these by-laws.

It is scarcely necessary to give specific instances of the anomalous conditions as created by the administration of obsolete and effete by-laws. Cases are of daily occurrence where one section of the local administration condemns work that has previously been passed as satisfactory by another section of the same administrative authority.

It is to be hoped that the paper will be brought to the notice of the Local Government Board's leading officials, and that their progressive tendencies will cause them to put in motion the machinery necessary for the removal of the present legal obstructions to the progress of sanitation.

It would be of great material advantage to the public if the advice of practical men was obtained during the construction and compilation of by-laws that have such an important bearing upon public health.

It is claimed that there are few exceptions where any local conditions necessitate a variation in either the method or practice of executing the work, or in the material, form or type of accessories used in connection therewith to secure the objects of efficient sanitation in so far as such work lies within the curtilage of the owner's property, as distinct from the responsibility which falls to the local governing authority. This being the case, all that makes for a variation of standard must of necessity bring in its train varying degrees of efficiency in an object that can only be secured permanently by the highest point in this respect.

It has been contended in opposition to this principle that some such necessity may exist in the case of the hotel, country house or mansion, but that in the smaller house, cottage and artisan's dwelling, although perhaps desirable, the cost would be prohibitive.

It requires little to show that this contention provides the strongest argumentative proof of the necessity for a high standard of efficiency especially in regard to the smaller type of house.

The hotel has usually advantages in attention and the more or less temporary occupation of its inhabitants, as also the greater personal cleanliness of the class to which they belong. The country house or mansion, besides some of these advantages, has the additional ones of free circulation of air round and about, as also the benefits conferred by that greatest of sanitarians—fresh air and sunlight.

The cottage or small house, especially of the type common to our industrial towns, closely grouped as they are in long rows or streets, with the intersection in front of a none too wide street, and two rows of often ill-kept back yards and a back street behind, necessitate by the conditions of their environment all that science guided by common sense can dictate to secure the most permanent sanitary conditions, which must so far as possible be designed and constructed to require the minimum amount of attention on the part of their occupiers.

Whilst it is not admitted that the cost of securing these better conditions will be materially affected by the adoption of a better standard than at present obtains generally, there would be compensating advantages in a decreased cost in maintenance to the owner, and to the public rates would accrue any advantage consequent of the saving by this means in the care and treatment of infectious diseases, which are attributed to sanitary defects, and the cost and annoyance of reinspection which must follow any such outbreak. Beyond this is the consideration for the health of the most important section of the community who, by conditions inseparable from their position and surroundings, are susceptible to the origin and spread of preventible disease.

The existing lack of standard and absence of connected principles, consequent upon anomalies and variation in interpretation of which most existing by-laws admit, create difficulties of confusion to the employer and his workmen, and neutralise the confidence with which the inspector or official should inspire them, as also it detracts from the cordial co-operation between both upon which depends the success of their different duties.

This is emphasised when confronted with the technical training of the employer, workman and inspector, which have been on the same lines and possibly the same technical class, but which converge when put into actual practice.

The inspector is of necessity guided by the conditions and methods dictated in the by-laws and regulations peculiar to the district, and which, wholly or in part, do not synchronise with the teaching which secured his qualification; and the workman, by knowledge gained of experience, is fully aware that if the principles he has been taught are carried into actual practice they will not be approved by the authority which exercises power to condemn or approve his work.

The by-laws which regulate the capacity, construction and testing of domestic drains provide an excellent illustration of this point. In many districts the selection from the model by-laws prescribe that any water-closet or closets shall discharge into a drain 6-inch diameter, in others the size is 4 inches, but in many cases when the 6-inch drain is prescribed it is not insisted upon by the local inspector, who may very properly decide that a drain of smaller internal capacity will answer the purpose better. No variation of local conditions can possibly warrant so wide a selection of size in drains for this always similar purpose.

The principles taught in the technical classes tend to the minimum capacity of a conduit to convey putrefactive matter, to prevent fouling and the subsequent process of putrefaction in the conduit, and also to ensure that the air in the drain shall be displaced as frequently as possible. To illustrate this students are taught and examination tests made on the discharging capacity of pipes with different falls, running full and half-full, and when the student compares the volume of water which a pipe of 4-inch diameter, running half-full with a fall of 1 in 60, with the quantity of liquid which is limited by the capacity of the flushing tank of a water-closet, he cannot reconcile the necessity for even a 4-inch pipe to do its work effectually.

Where a 6-inch pipe is insisted upon for one or even a number of closets he cannot understand how fouling of the pipe is to be prevented or the necessary displacement of air is to be effected.

As pointed out, this in a less degree is liable to occur when a 4-inch pipe is used, and it will thus be found that even a smaller pipe may with advantage be substituted, so long as provision is made for removing obstructions which may occur through misuse before these pass out of easy reach at the point of their entrance into the domestic drainage system.

Although for fixed reasons it may be considered impracticable to use a pipe of less diameter than 3 inches for a soil pipe or soil drain, and 3 inches does not appear to be so much less a diameter than 4 inches, the internal area is not of the same proportion as the diameter, and with a 3-inch or even 3½-inch pipe the very desirable factor of pressure will come into force. It is needless to dwell upon the many advantages obtained when drains are worked under pressure in preventing sedimentation and fouling.

The material from which drain pipes are made, the method of laying and jointing, are also matters on which there is great variation in the by-laws or their interpretation in even adjacent districts.

In some districts glazed fireclay may be used; others require stoneware, and (unfortunately) only a few iron; some require sockets and spigots unglazed; others with these parts of special capacity with serrations to permit of caulking; similarly some insist upon joints made of cement with or without spun yarn; others bituminous compound; and others again are satisfied with puddle clay.

In regard to the last-mentioned but now almost obsolete method of jointing, it is somewhat surprising that there are to be found engineers and architects who claim for this method of filling the joints of even soil drains that it provides a flexible joint where the drain is liable to movement.

Unfortunately this opinion is consistent with many of those errors which operate against all that makes for permanency and efficiency in this and other parts of sanitary work, in so far that having selected a weak form of conduit it is necessary to provide a weak joint to prevent its breaking.

(To be concluded.)

The Report of the Board of Management of the Manchester Royal Infirmary states that there is provision at the new hospital for 592 beds, with all the conveniences and resources suitable for a twentieth-century hospital. The complete figures as to cost are not yet available, but the Board have no reason to anticipate that the estimate will be materially increased. During 1908 135,501*l.* was paid to the contractors, professional advisers, and others for the structure and fittings, and 7,951*l.* to contractors for furniture and so forth. The total expenditure on the new hospital, exclusive of interest, now amounts to 446,998*l.*

THE OLD RECORDS OF YORK.

MR. WILLIAM GILES, deputy town clerk, who has been engaged for several years in the work of examining, classifying, repairing and restoring the ancient books and other records of the city, has now completed this work and has presented an interesting report to the finance committee, in which he says:—

The work of renovating and restoring the old books and other records of the Corporation, many of which were so much damaged by the great flood of October 1892, has been completed. They have also been classified and catalogued, in order that the Corporation might have a permanent record of the city's ancient and valuable documents, no such catalogue having ever before been compiled.

The records were at one time kept in the building known as St. William's Chapel on Ouse Bridge (now the site of Messrs. Boyes & Co.'s remnant warehouse), which was used for municipal purposes as well as a prison, &c., but about a century and a half ago removed thence to the Guildhall and there kept, some in a closet under the steps leading to the old Council chamber and others in an adjacent strong room built for the purpose and now absorbed in the more recently built muniment room.

Here they remained until they were removed to the strong room provided for them in the basement of the present municipal offices.

They had been there but a very short time when the flood occurred which inundated the basement of the building and saturated the greater portion of the records, doing considerable damage to many of them.

Irrespective of this damage, however, a large number of the documents, both books and MSS., had been for a long period in a very dilapidated condition, caused chiefly by damp of long standing, appearances undoubtedly pointing to the time when they were kept on Ouse Bridge. So much were some of them affected by this cause that they were gradually mouldering away, and the saturation by the flood referred to only made their condition still worse, and it was but a question of time when they would have fallen to pieces and been lost altogether.

When it was ascertained how seriously the documents had been affected by the flood, a request was made to the Chief Commissioner of the Public Record Office, London, to permit some gentleman connected with that Department to come down and advise as to the best method of treatment to be adopted for their restoration. This request was at once courteously acceded to, and Mr. A. T. Watson, of the Record Office, came down and gave his valuable advice and assistance.

It was deemed necessary to at once send a few of the more valuable books, as well as several other documents, to be repaired at the Record Office (permission having been obtained for that purpose), leaving the remainder to be dealt with here.

As the work of renovating the documents was of a special nature and it was deemed desirable that it should be done at the Guildhall, I offered to undertake the work in my own time, with the assistance of a competent bookbinder. The committee agreeing, I made arrangements accordingly.

The work has been long and laborious, owing to the large number of books and documents requiring to be dealt with and the dilapidated condition in which many (in fact most) of the records were in, as already mentioned.

A considerable number of the books were without backs or with portions of backs only, whilst many of the leaves were badly mutilated and dirty; some others were made up of so many sheets of paper folded together and then stitched through to a skin of parchment or thick paper for a back, exposing the leaves for some distance from the edges to dirt and mutilation. Some others had first been written on sheets of paper, then folded and sewn together, so that part of the writing was actually in the folds and could not be read. In these latter cases every sheet (many hundreds) had to be cleaned and repaired, and then carefully cut down the centre and rejoined so as to show the writing clear of the folding when the books were rebound. In fact, most of the House or Council books, as well as numerous others, have necessitated every leaf to be specially treated to preserve them.

In the case of the Chamberlains' books of accounts, some of them were so affected by the damp already alluded to and by the flood that the greatest possible difficulty was experienced in repairing them. The Chamberlains' rolls, written on parchment, were also difficult to deal with, and so of many of the other documents.

The treatment of restoration necessarily required the documents to undergo several processes, each involving considerable care and time.

No trouble or pains have, however, been spared to restore the documents as efficiently as possible and which their value as records demanded, and with proper care in their future keeping they will now last for centuries.

It is matter of great satisfaction to find that, notwithstanding the damage done in the past, both by damp and water, by far the greater portion of the books and other records, and those the most interesting and valuable, are now in a good state of preservation, the writing in many instances being almost as clear and distinct as when first written. This much cannot be said of the more modern documents, many of which, however, are of no great value as records.

Most of the books have had to be entirely rebound, owing to the absence or the dilapidated condition of the old covers, but where possible the old bindings have been re-used. The Chambberlains' books of accounts were originally kept in yearly volumes, but with a view to economy and simplification of arrangement several yearly accounts of the earlier series have been bound as one volume, all as uniform in size as possible. The later volumes of the accounts have been rebound in their original form and covers, their condition permitting of this being done. The Chamberlains' accounts on long rolls of parchment have also been arranged in sections of years and placed in suitable cases, labelled and numbered for easy reference.

1. *Charlters and Letters Patent.*—There is a unique and valuable collection of Charters (some fifty in number) granted to the city by various monarchs, the earliest extant being one granted by Henry II.—between 1155 and 1162. This is, however, certainly not the first Charter granted to the city, inasmuch as mention is made in it of one granted by Henry I., and doubtless others were granted still earlier. This Charter of Henry II. granted to the citizens "all their liberties, laws and customs, and by name the Gild of the Merchants and Hanses in England and Normandy, and their Lastages, throughout all the Coasts of the Sea, quit as they ever most freely and best had them in the time of King Henry our grandfather; and We will and firmly command that they have and hold the aforesaid liberties and customs with all the liberties belonging to their aforesaid Gild and to their Hanses, as well and as peaceably and as freely and quietly as ever they best most freely and most quietly had and held them in the time of the aforesaid King Henry our grandfather." Many subsequent Charters practically confirmed these rights, privileges and immunities, though couched in different terms, and, in later times especially, in much lengthier documents than the earlier ones. Others relate to the manner of electing mayors, sheriffs and other officers and the common council; the transaction of business of the Corporation and other matters; also to the fee farm payable by the city, the freedom of the citizens from arrest or prosecution by outside persons, to the markets and fairs of the city, the river Ouse, the reparation of the bridges over the Ouse and Foss, and to many other subjects. There are also "Pardons" to the citizens, with restitution of liberties, &c., which they had forfeited for some act of displeasure to some particular monarch; and there are others which relate to Guilds (or Gilds) formerly existing in the city—for instance, Corpus Christi, St. Christopher and St. George. More modern legislation has, of course, rendered nugatory most of these charters.

2. Three volumes contain entries of various events and other matters connected with the city from an early period and are amongst the most valuable and interesting of the records. Drake and other historians have quoted from them. The volumes also contain a good many of the ordinances of the gilds of the city.

3. *Corporation House or Minute Books.*—These contain the minutes and proceedings of the Corporation, and commence with the year 1476 and continue down to the present time. They are valuable and interesting in their narration of the doings of the Corporation and of events connected with the city, and help largely to make up the city's history. It is satisfactory to know that these House Books have been preserved without a break for so long a period, when other documents have long ago been lost. I have arranged these books in two series, viz.:—First series, from 1476 to 1834-5 (forming fifty volumes), representing the period of the Old Corporation; second series, from 1835 to the present time, representing the new (or reformed) Corporation under the Municipal Corporations Act of 1835.

4. *Freemen's Rolls or Registers.*—These volumes contain

Digitized by Google

the names of the persons admitted to the freedom of the city. They commence with the year 1272 and continue to the present time, there being eight volumes. Doubtless there would be "freemen" long before the year mentioned (1272) and rolls or registers kept of them, but if so the records have been lost or destroyed long ago. It may be mentioned that in the earliest volume of freemen there is a list of mayors and bailiffs (now sheriffs) of the city from 1272 to 1670, as also various other entries of matters relating to the city.

In connection with the Freemen's Rolls there are several register books of apprentice indentures, one commencing in the time of Edward IV. (1461) and continuing, with certain omissions, to about 1502; another from 1573 to 1688; and then a series from 1721 to the present time.

5. *Chamberlains' and Bridgemasters' Rolls and Books of Accounts.*—There are altogether about 450 rolls and ninety-six books. They represent the accounts of the Corporation in earlier times, and were kept on rolls of parchment and in books, each year having its separate roll and book. The rolls commence in 1398 and continue down to 1835, but not in a complete series, inasmuch as many rolls have been lost at some time or other. The books commence in 1446 and continue to 1816, but here again a number of them have been lost. The rolls themselves were signed by the Chamberlains and were audited in proper form, whereas the books were neither signed nor audited. Yet in many instances more details of the items of receipt and expenditure are given in the books than in the rolls. Numerous original bills and memoranda relating to and explanatory of the accounts were kept loosely with the books or in bundles, a considerable number of which I have, after infinite trouble, collected, collated and inserted in their proper places in the various volumes. These rolls and books of accounts are interesting in their way.

6. A number of volumes of manuscripts and other papers and memoranda relating to the city, the Corporation and its business and other matters.

There is also the original letter from Sir Martin Bowes, Kt. (dated 1549), presenting the sword to the city which is usually carried before the Lord Mayor except on State occasions, when the older and larger sword is used.

Besides the foregoing there are many title deeds relating to properties, as well as other books and documents, all more or less of value and interest.

Altogether the house books, chamberlains' books, freemen, quarter sessions and other books number upwards of 400 volumes, and the various other documents also number many hundreds.

The catalogue which I have prepared of the records will afford easy reference to them, the classification and letters or numbers therein corresponding with similar letters or numbers on the various documents and books themselves.

As regards the charters, which vary considerably in size, I would suggest that they be placed in drawers to avoid rolling up.

The muniment room, built a few years ago outside the Guildhall, is not in a suitable condition for the keeping of these records, owing chiefly to dampness, and it would not be prudent to put them there until the room is made perfectly dry, it being absolutely essential to keep these restored documents free from damp. Until this is done they should remain where they are now placed, viz. in the closet adjoining upon and opening into the muniment room.

GENERAL.

The London Topographical Society will hold their annual meeting on the 19th inst. in the Lecture Theatre, Burlington Gardens, when Lord Rosebery, K.G., president, will deliver the annual address.

A Triptych with paintings upon oak panels in the sanctuary of the parish church, Oldham, was dedicated last week. The paintings represent Our Lord seated upon a throne of gold in the midst of seven golden candlesticks and having seven stars in His right hand. On either side are kneeling figures of the B. V. Mary and St. John Baptist. The four archangels, with a host of angels playing musical instruments, surround the throne. Below are groups of figures representative of the Church's history. The paintings, which contain upwards of seventy figures, are by Mr. E. Stanley Watkins, of Ealing.

A Bust has been presented to Bournemouth of Mr. C. Crabbe Creeke, the first surveyor to the town, who many years ago laid out the open spaces, &c.

Mr. Edward Augustus Gruning, F.R.I.B.A., F.S.I., of 3 Holland Park, and of 25 Gresham House, Old Broad Street, architect, who died in December last, aged seventy-one, left estate of the value of 188,377*l.* By his will he left to his assistant, Herbert Pelly, the lease of his offices and the contents thereof, the benefit of all contracts and book debts subject to the payment of business liabilities, so that he may be able to carry on for his own benefit the testator's business without using his name, except for public announcement that he has succeeded to the business. To his clerk, Edward Dodd, an annuity of 52*l.* To each other clerk of two years' service three months' wages.

The Court of Common Council have granted the request of Archdeacon Sinclair for authority to take steps to enable the Dean and Chapter of St. Paul's to carry out the terms of the bequest of Mr. H. C. Richards, K.C., who left 5,000*l.* for the restoration of St. Paul's Preaching Cross, or the erection of a memorial of it.

At the Meeting of the Waterford Corporation last week the Mayor reported that Messrs. Baker & Hurtzig, engineers, were willing to submit plans and estimate—not detailed contract plans—for a bridge over the Suir suitable to the requirements of Waterford, to be laid before the Privy Council on appeal for a fee of 250 guineas. Giving evidence in support of these plans and estimate would be based on a personal fee of 15 guineas a day to Mr. Hurtzig. The evidence would be restricted to the plans, and the firm would not undertake a criticism of the plans submitted by the Viceregal Commission. The Council decided to accept the offer of a ferro-concrete firm to submit a plan and estimate free of cost, as well as to obtain the plans and estimate from Messrs. Baker & Hurtzig.

Messrs. W. H. & P. B. Strudwick, the quantity surveyors in connection with the enlargement and improvement of the Barrow Hill Road school (Marylebone) have asked the London County Council that they may be allowed a fee of 2½ per cent. in respect of the bill "exterior painting and repairs," amounting to 501*l.* A request has also been received from Mr. C. W. Brooks, the quantity surveyor in connection with the enlargement of the "Oliver Goldsmith" school (Camberwell), that he may be allowed a fee of 2½ per cent. in respect of the bill "works to existing buildings," amounting to 292*l.* 11*s.* 2*d.* The ordinary fee in each case is 2 per cent., but, in view of the nature of the work, the education committee are of opinion that the claims should be allowed.

Sir Henry Tanner, of the Office of Works, has written a letter to the Westminster City Council stating that the new buildings at the east end of the Mall would be completed by about the end of 1909, and that it would then be possible to open the road through to Charing Cross.

Mr. Thomas Brock, R.A., has practically finished the plaster model for the statue of Sir Henry Irving, and all that now remains therefore is the casting of the figure in bronze, which is of necessity a matter of time. There is every reason to hope that the statue will be erected on the site arranged for it at the back of the National Portrait Gallery in Charing Cross Road during the autumn of the present year.

Messrs. Swinburne, Cooper & Baillie have joined with Messrs. O'Gorman & Cozens-Hardy. The new firm is entitled Swinburne, O'Gorman & Baillie, and will continue to practise as consulting engineers in electrical, automobile and general work at 82 Victoria Street, S.W.

Mr. W. R. Cooper, A.M.I.C.E., has severed his connection with Messrs. Swinburne, Cooper & Baillie, and will continue to practise as consulting engineer in electrical and mechanical engineering and experimental work at 82 Victoria Street, S.W.

The Triennial Competition open to Great Britain for the Alexander Thomson Memorial Studentship, value 60*l.*, under the management of the Council of the Glasgow Institute of Architects as trustees, has this year resulted in favour of Mr. David Robertson, a second prize of 20*l.* being awarded to Mr. Alexander Thomson Scott, both of Glasgow. Five sets were submitted. The winner is in the office of Messrs. Stewart & Paterson, Blythswood Square, Glasgow, and the second prizeman is with Messrs. Campbell Douglas & A. N. Paterson, St. Vincent Street, and both are students of the Glasgow School of Architecture.

Mr. E. Russell Taylor, architect and surveyor, of Castle Street, Liverpool, at a meeting of the executive committee of the Conservatives and Unionists of the county borough of Lancaster, was adopted as the Parliamentary candidate for the borough at the next election.

The Architect.

THE WEEK.

THE remarkable prices obtained at the BENSON collection of coins cannot fail to direct the attention of the general public to the beauties of Greek art, and the more so as this valuable collection seems to have been formed with an appreciation of the artistic excellence rather than the rarity of the specimens included. It takes but little to direct the current of taste amongst the Philistines, and the fact that an eminent London publisher has thought it well to bring out a translation of a French work on Greek vase painting, mainly a monograph of one particular artist, seems further to indicate that amongst those whose business it is to feel most skilfully the pulse of the general public there is a belief that Greek art stands an excellent chance of becoming fashionable. If this be so, and it seems more than likely, architecture, reflecting as it always does the feeling of the age, may be expected to embody, let us hope, rather the spirit than the forms of Greek work. The days are gone of archæologically correct plagiarism of the details of the Parthenon, the Erechtheion, and the Choragic Monument of LYSICRATES, that was the aim of the nineteenth century revivalists of Greek architecture, and Professor BERESFORD PITE has already shown us how Greek feeling can be expressed in a modern building without slavish copyism. The works of Greek THOMSON, though their author is now departed, still teach us the same lesson.

THE Liverpool Corporation (Streets and Buildings) Act, 1908, confers on the Corporation of the city of Liverpool further powers for the better regulation of buildings, the formation of streets, and the laying-out and development of estates within the city. The Act requires all new streets or the widening of existing streets to be in accordance with plans previously approved by the Corporation. It gives the Corporation power to determine what new street shall be a main thoroughfare, thereby entailing a width of eighty feet, or by paying compensation to require any new street to be of any width they see fit. In any new street the person who forms the street is to suggest the building line, which is then subject to the approval of the Corporation. In any existing street the Corporation may set back the line of frontage and require all buildings projecting beyond that line to be pulled down, compensation being paid to the owners. They may similarly widen the street by requiring the owners to give up the land between such line of frontage and the street, paying compensation only in those cases where the increased width of the street is more than the width the Corporation are entitled to prescribe under their by-laws for a new street. The Act also provides that no new street shall be laid out exceeding one hundred and fifty yards in length without at least one intersecting street in every one hundred and fifty yards, and that not more than thirty houses shall be erected on either side of any new street between any two consecutive intersecting streets. In the laying-out of new streets the Corporation may require the boundaries of any adjacent estates to be rearranged by mutual exchange, or by payment of money by one owner to another with the consent of the vendor, or by purchase by the Corporation. Provision is also made for the formation of public gardens or recreation grounds, and the ornamental laying-out of parts of streets.

THE terrible theatre disaster at Acapulco, Mexico, emphasises, first of all, the strictness of supervision necessary for cinematograph entertainments, the popularity of which we see in London is undoubtedly already great. Many such entertainments are now being given in places that are under no sort of control, particularly in the suburbs where the authority of the London County Council does not reach, and parish halls, church rooms, and schoolrooms of considerable seating capacity but with primitive and insufficient exits are occasionally devoted to a cinematograph show, invariably attracting a crowded audience. We have in our mind particularly a lecture hall in a London suburb in which, at the very time that the theatre at Acapulco was blazing, an audience of some five hundred people were enjoying an amateur cinematograph entertainment. The hall in question has a wooden roof with matchboarded ceiling, matchboarded dado, and wooden floor. The only doors into the hall are the public entrance, through a short corridor, with a doorway 4 feet 6 inches wide, and a 3 feet doorway to the lecturer's ante room, and these conditions may be found in scores if not hundreds of other instances. All architects who have to plan such buildings should regard the theatre regulations of the London County Council as their standard, morally if not legally. The Acapulco catastrophe further gives point to the opposition of the members of the Progressive party to the relaxation of their regulations brought forward by the present Theatres and Music Halls Committee of the London County Council.

BY the death of Dr. RUSSELL STURGIS, New York has lost not only a well-known and able practising architect, but one of the most accomplished of modern writers on architecture. As an architect his work is to be seen in several of the Yale University buildings and in many large office premises and residences in New York and the Eastern States. As an author his works have been largely intended to inform the layman as well as the professional student, and include "A History of Architecture"; "A Dictionary of Architecture and Building"; "European Architecture"; "How to Judge Architecture"; "The Appreciation of Sculpture"; "The Appreciation of Pictures"; "Bibliography of Fine Art"; "Decorative Windows in England and America"; "Ruskin on Architecture" (an introduction to the Ruskin volume in the World's Great Books); "Michel Angelo" (in JOHNSON'S Universal Cyclopædia); "A Study of the Artist's Way of Working."

THE British School of Archæology in Athens is engaged on a very interesting excavation of the site of the Temple of Artemis Orthia at Sparta. This was the temple at which the well-known curious ritual of the flogging of the boys was practised, and seems to have maintained a remarkable continuity of existence. The earliest building, of the ninth century B.C., was of brick with timber framing, and its interior was divided lengthwise by a row of wooden columns. This was destroyed at the end of the seventh century, and was replaced at the beginning of the sixth century by a new building superimposed on the remains of the older, and itself rebuilt in the Hellenistic period. A fragment of an archaic Doric capital of the sixth century temple was found, and a votive stele with a representation in relief of the Temple of Artemis, showing this to have been "distyle in antis." These discoveries go far to decide what has hitherto been mainly a matter of conjecture—the wood or stone origin of the Doric order. There can now be little doubt that the early Doric temple had walls of rough material, brick or rubble, with pteromata ended by wooden antæ, and between these "in antis" two sturdy Doric columns, built like our own Norman piers, of very massive proportions in small stones, the whole crowned by a wooden roof, whose construction was afterwards traditionally copied in the Doric entablature of stone or marble. Thus we have also an explanation of the universal divergence in Greek work of the form of the anta cap and the capital of a column, the former being like the entablature a traditional survival of a former wooden feature, whilst the latter was always of stone. Besides the architectural data obtained from these excavations, the smaller objects found, ivory carvings, cast-lead figurines and pottery prove that artistically Sparta was at its zenith in the eighth and seventh centuries, and decayed in the sixth and fifth with the development of military strength and enthusiasm. Especially is the evidence clear that what has hitherto been regarded as Cyrenaic ware must now be recognised as Laconian. The decline of the art of Sparta at the time when that of Athens was approaching its highest excellence may perhaps account for the employment of the Athenian ICTINUS in the building of the Apollo Temple at Bassae.

THE ETHICS OF COMPETITIONS.—II.

HAVING considered the ethics of competitions in the abstract, we can now turn our attention to the question of the manner in which they are conducted as a matter of fact.

Admitting that in the abstract open competitions are desirable and right, do we find that they are at present conducted with the minimum of wasted labour and money to the unsuccessful competitors? There is no doubt that the answer must be decidedly in the negative. In almost every open competition, particularly in these slack times, when the number of competitors is so largely increased by the prevalent dearth of remunerative employment, the cost to the architectural profession as a whole of the competition drawings exceeds the profit that the successful architect can hope to obtain from carrying out the work; in many cases the cost of the drawings submitted exceeds the gross amount of the fee received by the architect who erects the building, and sometimes, as in the case of a competition for a new church in Exeter some few years ago, the competitors, at a modest computation, actually spent on the preparation of their drawings a sum greater than the entire cost of the building. From a business point of view the toleration of such a drain on the resources of the architectural profession is simply madness, and it is no wonder that there are many architects who, for this reason, would advocate the entire abolition of the competition system.

Our experience in this country is not singular, for our American *confrères* labour under the same incubus. Mr. Cass Gilbert, the President of the American Institute of Architects, in his opening address to the recent annual Convention of that Institute, estimated that the architects of the United States annually expend over one million dollars in competitions from which they receive no return.

Such a state of things can in no way be considered right. It is certainly wrong that the public should receive the advantages of the open competition system at such an enormous cost of unpaid labour to the architectural profession as a whole. We believe that the British public is no less fair-minded than the American, and that the words of Mr. Gilbert would apply equally in this country as in the States when he said:—"If fault there be, it lies in ourselves. The correction is in our power. The public is eager to understand and ready to accept the professional man's point of view if it—that view—is sane and consistent. The public does not know, and cannot understand this great waste. It is well that we should understand it and take serious thought."

How is this great waste to be avoided? One effectual method is to adopt the principle of limited competitions, with the essential proviso that each competitor shall be paid an honorarium that will at least cover his out-of-pocket expenses and give him some reward also for the exercise of his skill and ability. This method naturally is usually approved by those who are already distinguished and well known, those, in fact, who may reasonably expect to be invited to take part in a limited competition. But a limited competition, after all, is but an extension of the principle of direct commission, and precludes the abstract advantages of the open competition. A private individual is fully justified in giving a direct commission either for reasons of friendship or from his admiration or partiality for the work of some particular architect. He might be unable to decide between the claims and merits of a number of architects, and would then be perfectly right in inviting them to a limited competition, paying them for their services. With certain limitations such bodies as the committee of a church or chapel, the board of directors of a limited company, are in a similar position and equally justified in giving a direct commission to some particular architect. Being to a certain extent in a fiduciary position, they could not rightly select an architect merely because he happened to be the son of the chairman, but they might quite correctly do so if they believed that the interests of their subscribers or their shareholders would be safe in his hands. Hence, also, they might arrange to decide their differences of opinion as to the selection of the right man for their work by the help of a limited competition. The private individual or a quasi-private body of individuals is then correctly within his rights, both morally and legally, in adopting the principle of limited competition.

Public bodies administering public money are, however, on quite a different footing. It is their duty to expend public funds to the best advantage of the public, and this includes not only the erection of the most useful and most economical building in any particular case, but the advancement of the art of architecture. For them, as the Royal Institute of British Architects has affirmed, open competitions are the only right course.

Within the last few years a new method of limiting competitions has been adopted by some public bodies, limitation by geographical measurement. Competitions for public buildings have been restricted to architects residing or practising within a given county or within a certain radius or other geographical area. As we cannot suppose that the object of this method is merely to diminish the number of competitors the arguments in favour of it appear to be two:—First, that those architects who, as ratepayers, contribute to the cost of the building, should alone have the opportunity of employment; second, that the cost of travelling expenses to be paid by the public would thus be minimised. The first argument ignores the fact that in our system of national finance local public bodies are State-aided by the credit of the country, even when actual money grants are not made from the national exchequer, so that when the county of Cornwall raises a loan for public works, the architect who lives in Newcastle and pays his income tax is assisting in procuring favourable terms for that loan. The second argument has more validity, but the end desired might be as readily achieved by limiting the allowance for travelling expenses to a moderate amount.

The geographically limited competition has already increased the employment of "ghosts," either in the form of paid extraneous assistance or in that of *sub rosa* partnership, and this is the natural corollary of the system. Then again this adaptation of the boycott is likely to lead to reprisals, and if the London architect is barred from earning money in Lancashire he will be tempted in his turn to bar Lancashire manufacturers and tradesmen from work in his clients' buildings. On all counts therefore we may consider the geographically limited competition wrong in principle and injurious in effect to the promoters as well as to the art of architecture.

We have now to consider whether the great waste in the practical working of open competitions can be obviated or minimised. Something has already been accomplished in this direction by dividing competitions into two stages, the first open to all, the second limited to the authors of the most promising designs in the first, and carrying with it an honorarium for each of the contestants in the final essay. Our German colleagues have attempted the elimination of the great waste by other procedure. They have reduced the scale of plans, elevations, and sections to the smallest possible, effacing all detail from the two latter classes of drawings and leaving them merely to express mass and composition. Perspectives, too, are similarly restricted to the broad representation of general effect. The German architects have also succeeded in inducing their public to offer premiums far more numerous and far more valuable than is the case with us, so that besides the actual winner a due proportion of the competitors receive payment that not only defrays their out-of-pocket expenses but would be very fair remuneration if the designs they have prepared were produced in response to a direct commission.

It seems to us that the great waste in open competition might be almost if not entirely eliminated by a combination of these methods of procedure. Let every open competition be conducted in two stages, the scale and number in the first being determined by the assessor and reduced by him to the absolute minimum he may deem necessary to enable him to judge which of the schemes submitted gives promise of a suitable design. Admitted that this would increase the number of competitors and of drawings that are utter rubbish, the work of unfledged and untrained ambitious office boys, there

Digitized by Google

would still remain a considerable number that although perhaps not good enough to be allowed inclusion in the second stage, still merit some consideration and payment. Let a considerable percentage on the cost of the building be at the disposal of the assessor to defray the out-of-pocket expenses of the most worthy of the unsuccessful competitors. All the participants in the second stage should receive an honorarium sufficient to cover the cost of their drawings in both first and second stages, and the premiums should be sufficient to reward those nearest in merit to the winner with an adequate return for their skill and ability.

Our suggestion may be met with the objection that its adoption would be possible only in Utopia, but we are completely in accord with the views propounded by Mr. CASS GILBERT, and believe that the British public is quite prepared to deal fairly with the profession of architecture if it is only properly awakened to the ethics of competitions. We commend this view to the consideration of the Competitions Committee of the Royal Institute of British Architects.

STEELWORK.—V.

By C. V. CHILDS, A.M.I.C.E.

Stanchions.

THE usual type used in England is the plain joist for light loads, or for heavy loads compounds, i.e., one or more joists with plates rivetted to the flanges. In America the stanchions, or, as they are called in that country, the columns, are usually built up of plates and angles or Z-bars; each firm has more or less standardised its own type, e.g., the standard column of the Carnegie Steel Company is the Z-bar type, built up of four Z-bars rivetted with two rows of rivets to a central web plate, flange plates being rivetted on, for heavier columns.

The reason joist sections were not more utilised was partly because the American I-beam (Anglicé, joist) is lighter in section than English ones of the same depth; the main reason however was, that when steel stanchions were first coming into general use and displacing cast-iron columns, there was a combination among the chief rolling-mill owners, known as the "Beam pool," to keep up the price of I-beams and channels; for years the price of plain beams was quoted at 3.1 cents. per lb. (equivalent to about 14*l.* 10*s.* per ton), but when hard times came, the strain was too great and mistakes (so they were called) became so frequent in the estimates, that the "pool" came to a timely end. The effect however was that sections, other than I-beams or channels, were used in preference to these shapes, the price of which was not governed by the "Beam pool," such as angles, plates and Z-bars; but before the pool was dissolved each firm had settled on and standardised its own form of column.

Of all these the Z-bar column was probably the most convenient for use in buildings. It is practically unknown in this country owing to the English mills rolling but few sizes, and these being too large in section.

Apart from stanchions a word might be said in favour of Z-bars for another use, viz., roof purlins, as they are the best of all sections for this purpose, being stiff in all directions and easily trussed where purlins of long spans are desired.

Even of more importance than that the section of a stanchion should be economical as regards carrying capacity (i.e., having a large radius of gyration), is that it should be of such a form that splice plates, connections and brackets can be easily and effectively rivetted to the shaft.

As in the case of a bridge, the weakest part is most probably to be found in some joint, rather than in the main members, so also in a stanchion. The ideal point of applying the loads is directly to the axis of the shaft; the farther the bearings of the girders are away from the central axis, so much the worse for the stanchion; eccentricity of loading makes it become the most uneconomical member an engineer is called upon to design, viz., a beam and strut combined.

Taken all in all, the joist or compound is as convenient a form of stanchion as any other. It is easy to make; the joists and plates are largely stocked, which means quickness of delivery; they can be simply spliced, so as to form a continuous stanchion from basement to roof; brackets to carry the girders can be rivetted on in any position, or at any level; they are easily built and bonded into the walls, or cased in to form isolated stanchions; their size can be kept within reasonable dimensions; their strength as a beam is serviceable in withstanding eccentric loading; brackets, rivetted to the webs, bring the girder loads very close to the axis of the stanchion, and in the case of those rivetted to the flanges, the transverse resistance is greater in this direction.

Other forms there are in general use in London, of which two may be mentioned, the Differdange beam, and the solid steel column. The Differdange beam is the enlarged joist section with very wide flanges, rolled by a universal mill process to as large a size as 30 inches deep by 12 inches wide; their chief advantage lies in the fact that a large amount of area is obtainable in one section, without the trouble of the drilling and rivetting necessary to obtain the same amount in a compound. A more than counterbalancing disadvantage is that they are only obtainable from abroad and that the steel contractor is dependent on one firm alone for its supply; whereas with the standard sections, he has the choice of many mills from which to secure what he needs. He can thus place his orders for the plain sections to suit the rolling programmes of the various rolling mills, a consideration where quick delivery is desired. The section itself is hardly compact enough for stanchions; if tested to destruction, it would probably fail in a similar manner to some full-sized Z-bar columns tested at the Watertown Arsenal, which were found to give way by twisting spirally, owing to the extremity of the flanges receiving insufficient support from the body of the section. It may be mentioned that the tests referred to above were made on full-sized steel columns to test the accuracy of the straight line formula, on which the strength of the Carnegie standard columns was calculated. The test showed that this formula was somewhat on the weak side, and gave too high an allowable stress especially for columns, whose ratio of length to radius of gyration was large.

The solid round steel column is more of a favourite with architects than with engineers; it is by no means an economical section, weight for weight with a compound section; its carrying capacity is somewhere in the neighbourhood of thirty per cent. inferior; the bases and caps are exceedingly heavy; connections of girders to the columns, unless the bearings are all at the level of the caps, are difficult and costly to make, and splicing is almost out of the question.

Their advantages lie altogether in their occupying the minimum of space; hence they are frequently used for isolated columns in shop windows to support the girders carrying the main front walls. Columns and stanchions in such a position—in fact, all isolated ones that support the main walls of a building—are the most important feature of the building; its entire safety depends on these stanchions. For this reason, as a safeguard against damage in case of a fire, the building laws might well be altered to insure their protection by compelling such stanchions to be encased with an absolutely fireproof material; preferably with interlocking casings, made of fire-brick, having an air-space between the casing and the column. No doubt casing stanchions in with solid concrete is a great protection; but nothing short of the best should be used in such cases; girders may buckle and still cling to the stanchions, but if these latter should fail, then it is a case of "when the tree breaks," in the nursery rhyme. The greatest danger to which firemen are exposed is that due to falling walls; for this reason all that is humanly possible should be done to protect the wall supports from destruction in case of fire.

Of the number of formulæ for designing the sizes of stanchions there appears to be no end; some are fairly simple, others are extremely complicated; some, when plotted with co-ordinates of stress per square inch against length divided by radius of gyration, give a straight line, others curves, reflex and otherwise.

The fact is an exact formula is an impossibility; the best is more or less guess work; two stanchions, similar in all respects, may give very different results when put to the test; any slight deviation in the centre of pressure shows considerably in the result of a test. The use of a stanchion formula is more to indicate the limits within which it is safe to work than to be slavishly adhered to. There are other considerations, besides a fractional amount of area, to be taken into account, such as how to build up the sections so that the upper stanchions can be easily spliced to the one beneath, or that the girders can be connected to them in a simple manner. The unsupported lengths of stanchions do not vary much, as they are generally tied in at the floor levels by the girders and the floor itself. Ten to 15 feet is about the average length in building work.

Digitized by Google

A very simple method, it can hardly be called a formula, is to allow as the safe load on a stanchion as many tons as the stanchion weighs in pounds per foot run; this is equivalent to 3⅓ tons per square inch on a joist section, or 3½ on compound sections (allowing five per cent. for rivets). For ordinary lengths, as stated above, this would be a fairly close average for the stress in all stanchions, just about right for the heavy joists and single joist compounds, rather too high for the smaller joists, and somewhat too low for large compounds. At any rate, it forms a basis for quickly calculating the entire weight of stanchions in a building, e.g., add the total load in tons together for each floor, multiply these by the heights of the respective floors, adding these totals together and allowing a percentage (from fifteen to twenty per cent. would be a fair average in ordinary cases) for bases and connections; the result is a very close approximation of the weight in pounds of all the stanchions.

If there is a large proportion of heavy loads, the average stress would probably be nearer four tons per square inch, in which case no percentage for bases and connections need be added; the difference between the 3⅓ and the 4 tons stresses automatically adds the percentage required.

There is one thing that has been wanted in the matter of formulæ, and that is a reduction in their number down to one recognised formula that will satisfy the requirements of the local authorities; then the designer will be in no doubt as to how to design stanchions for special buildings, the steelwork for which has to be approved by their engineers.

The system of running the stanchions in one length through two floors is not only good construction, but economical as well. The load on a single stanchion from one floor is usually not sufficient to require a pair of flange plates, e.g. supposing one floor load is 18 tons, equivalent to 1½ cwt. over a space 15 feet by 16 feet, this would require about 5 square inches of section; too small an amount to be conveniently added by stock sections; but two floors can be easily dealt with by two 10 inch by ½ inch plates or their equivalent, making 10 square inches for the two floors combined. The additional metal in the upper floor stanchion is more than compensated for by the labour and weight of the splicing, that would otherwise be necessary. The writer originally introduced this principle into American design, and it was first used either for the Mutual Reserve building, or the Savoy Hotel of New York; a further improvement has since been made by making alternate stanchions break joint at alternate floors, and this has now for many years been the approved American practice.

On the principle of probabilities, i.e., that the greater the number of floors the less likely they are to be fully loaded simultaneously, it is the custom in America to deduct a percentage off the live loads, sometimes as much as forty per cent. in the lower storeys, before designing the sections of the stanchions. It is questionable whether this is good practice; the saving is not as vast an amount as it may appear to be, the dead load of a building, especially an office one, being considerably more than the amount allowed for the live load. Moreover, stanchions are the most important members in the whole of the construction, and, once built in, are buried out of sight for future inspection, so that a little extra metal may not be considered wasteful in such a case; certainly these deductions affect internal stanchions more than exterior ones; but then, again, the latter receive a certain amount of lateral support by being bonded into the walls.

(To be continued.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last, at Conduit Street, W., Mr. Edwin T. Hall, vice-president, in the chair.

Mr. Alexander Graham, hon. secretary, announced the decease of Mr. Edward Augustus Ould, of Liverpool, Fellow, elected 1900.

Mr. H. V. Lanchester read a paper illustrated by sketches and lantern views, entitled—

Town and Country—Some Aspects of Town Planning.

He said it was his conviction that as a nation we regarded the relationship between town and country as the most important factor in town-planning. The average Englishman valued the country far above the town, and tolerated the latter only on account of its uses and convenience of intercommunication. The importance of ordered dignity and grace in the towns had never been appreciated by us as it was on the Continent, where the city took first place in the minds of all classes. It was characteristic, therefore, that such efforts as had been made towards the amelioration of town life had been rather in the direction of importing little scraps of the country into the town than in any studied method of expressing the city as such.

Valuing the country as they did, towns could only be considered in their relation to the surroundings, and in consequence more attention would be devoted to that relationship than to the actual embellishment of the city itself. The axiom might not be endorsed by the architect; it required some effort to accept it, but the author felt that it was by advancing town-planning on those lines that developments would result, and if architects as a profession admitted it they would not be prevented from making headway in other matters they had at heart. The superiority of the Continental peoples in the "grand manner" of city design was evident, and it seemed hopeless to attempt to emulate them by enlisting the general public. In the relationship however between town and country the sympathies of the nation were all assured, and Mr. Lanchester suggested that if as architects they could show that they were as the profession ought to be, reliable advisers, their views would be received with greater respect and confidence when proceeding with other projects. The deplorable character of the average suburb was so clearly comprehended by all who had devoted the slightest thought to the question that any remedy or amelioration offering itself would be eagerly studied. The central area of larger towns afforded a certain degree of satisfaction by reason of the dignity of buildings that had in the course of centuries accumulated there, but beyond those towns the country was broken up to give place to monotonous ranges of inanely designed and badly built houses, the slums of the future.

For the improvement of English towns there must be first the provision of worthy routes connecting the centre with the open country. Mr. Lanchester said he had examined a number of thoroughfares that had either failed or succeeded in satisfying him æsthetically, with the result that he believed it was possible to lay down a rough-and-ready rule. Either the height of the buildings should not exceed two-thirds of the width between them, unless it was at least one and a half times that width. Any proportion between those was unsatisfactory, though less so in the case of irregular streets, and with buildings having broken sky-lines. The narrow proportion was unsuited to residential districts and therefore the former one should be the limit, but in closely built commercial areas there would doubtless be many streets of the narrower type, though in the English climate it would be well to avoid them on an alignment east and west. If such a narrow street existed every effort should be made to open it up to the sun on the south side by recessing frontages and reducing the heights of buildings at certain points.

Mr. Lanchester then gave an imaginative sketch of an ideal realisation of town-planning ten years hence in any of our larger provincial cities. The buildings devoted to government, to recreation, to education were all properly grouped. The streets were wide, though without studied decorative effect. Open spaces and squares however were set out with monuments and groups of sculpture placed against suitable backgrounds, and where possible forming part of the composition of a building or group of buildings. All this arrangement would be controlled by an advisory committee of architects. New thoroughfares were opened up and radiating tubes in reinforced concrete, some 40 feet deep underground extended to docks and warehouses. Continuing towards the outer suburb they would pass a zone mainly occupied by residential hotels and the better class of tenement blocks. These had mostly been built under by-laws regulating the cubic amount of building that might be put on a given area, thus securing good gardens and open spaces between the six and seven storey blocks. Though the gardens were not all public property, it had been found convenient to place them in charge of the municipality. The inevitable tendency towards segregation had resulted in a certain amount of class grouping in that zone, but there were fortunately no hard and fast lines, and the districts mainly inhabited by the working classes differed but little in general appearance. The buildings were simpler in design, and a larger proportion of the open spaces was laid out as playground, but in other respects there was no perceptible difference. Beyond these was a great water avenue providing a convenient location for water sports. At the city end a circle a hundred and fifty feet in diameter was surrounded by a raised terrace formed by boat-houses, &c., with a terminal and two flanking monuments. From this there was an uninterrupted stretch of over three-quarters of a mile with two bridges, and then a wider basin surrounded by a

Digitized by Google

terraced embankment. The other main avenues out of the town would be more varied in character and linked up at intervals by cross roads and arcades with the main one. Duplicate streets with single-way traffic was the remedy against congestion on overworked routes. Following the water avenue they would reach on the south side of the road the university and group of buildings connected with it. The residential facilities of the educational group had been greatly extended, enabling undergraduates to have every opportunity for the cultivation of ideal studies without continual interruption by too close a contact with the business and commercial aspects of life. Immediately beyond the university group was the new museum and a park devoted to zoological and botanical collections. The park formed one of a series of inner parks all within two miles of the heart of the city. In laying out the inner parks their entrances and forecourts demanded careful study in order that they should accord with the treatment of the park, and with the character of the approaches. In some cases the forecourts would be designed in conjunction with a group of public buildings, and with one or more commemorative monuments, giving an opportunity for imaginative treatment unattainable where the buildings were of a commercial or domestic character. Passing from these to the larger and more remote parklands, they came to selected strips of country retaining as far as possible its rural character. There were also suburban villages gradually being reclaimed from the influence of the speculative builder. In other directions there would be a number of garden suburbs helping to raise ideals in the grouping and surroundings of small houses. Beyond the village suburb there would be some broken common on the far side of which the river had been dammed to make a spreading lake.

In his imaginary description Mr. Lanchester said he had endeavoured to be thoroughly practical, suggesting nothing that would not be easily within the powers of any of the great municipalities if once they realised the great desirability of such an achievement. Even if the possibility of some of the suggestions might appear to be open to doubt the claim that they ought to throw all their energy into an advance on the lines indicated would admit of none. England with its antiquities and traditions carefully preserved, its cities clean, convenient, and filled with noble and interesting works of art, with all the beauties of its countryside linked up with those of the town, would by reason of the variety of its scenery and shortness of its distances be in its way a complete garden. Its trees and hedgerows, and the brilliancy of its greenswards and meadows would, if only the works of man could be brought to a corresponding standard, make it a very jewel set in its surrounding seas, and a fit gathering place for all the great peoples springing from its soil.

Mr. SPEAIGHT said he was afraid that, although the paper was brilliant in its conception, the facts were rather in the clouds. He presumed that architects were desirous of bringing about public improvements on national lines, and suggested that endeavours towards that end often failed by making the schemes too fanciful and impracticable. In order to reach a successful issue such schemes should always be accompanied with a financial statement showing that the proposals were possible and financially sound, otherwise, no matter how well arranged and planned, they would not be carried out. They must remember that schemes for town improvement had to be submitted to shrewd business people before being adopted, and unless the plans were rational from the financial standpoint, and convincing in their practicability, they would never be realised.

Mr. W. H. LEVER, M.P., said he felt his sympathies were largely with the last speaker's views, but with one qualification. We were not in this country familiar with the best examples of town-planning in other parts of the world, and when practical schemes were attempted there was the opposition of town councillors and the engineer or surveyor attached to those bodies to be overcome. He was positive that if they could show to English people the much happier condition of those who lived in other countries we should be dissatisfied with our present lot and remedy it. They were influenced by the fact that from one end of England to the other, with the exception of Edinburgh, we had not a single example of how an important town should be properly planned. London had had great possibilities which were never realised. If they could keep great ideals before the people and gradually develop them he believed that within another fifty years, without serious expenditure of money, the character of the towns would be happily transformed. If they were willing to make their plans in advance, and had powers to control building operations, schemes for improvement could be undertaken without financial difficulty. Mr. Lever said the ignorance shown by town councillors and engineers in this respect was astonishing, and he quoted in support of his contention the case of a main street between Birkenhead and Chester, the opportunity for improving which by an 80-feet roadway was not taken because of the cost of maintenance. The speaker contrasted the planning of the cities of Sydney and Melbourne, and said the former exemplified the English influence, whereas Melbourne was laid out on the American plan with good wide streets. In Adelaide there was a combination of the two styles, and the city offered an example of a model arrangement.

Mr. A. TAYLOR, L.C.C., said he hoped they would all live ten years longer and see the ideas put forward in Mr. Lanchester's paper carried out. He had attended the meeting hoping to get some suggestions of what would be useful to the London County Council. All the members of that body were very much interested in the question and desirous of improving London. They had not been able to do very much because they were awaiting the publication of the town-planning scheme of Mr. John Burns. They hoped, however, to improve and extend London and its suburbs, and he was strongly in favour of the idea for promoting competitions amongst architects for that purpose. The borough councils would be asked to co-operate in the planning schemes, and for an area of twenty miles round London it was suggested the lines of development should be ruled by one general plan. Those of the members who had visited Vienna last year for the Congress would have realised how very much behind we were in town-planning and the effective arrangement of buildings and monuments.

Mr. RAYMOND UNWIN remarked that it was important to consider the suitability of the formal and the informal arrangement in town-planning, and he cited the Germans as having the most experience in schemes of that kind, and who were now departing fundamentally and entirely from the arrangement known as the "grand manner." Perhaps the Germans were going to the other extreme, for certainly in some recent undertakings they seemed to be losing the sense of scale. There was, however, a great deal, he thought, to be learnt from the German point of view, and he would have been glad therefore if the paper had dealt with the relations between formal and informal work. It was certainly a great problem to decide the relative importance of both methods.

Professor C. REILLY proposed a vote of thanks to Mr. Lanchester for his paper, and to Mr. Rickards for the sketches which illustrated it. Mr. DELISSA JOSEPH seconded the motion, and suggested that the appointment of a Minister of Fine Arts would aid towards the development of town-planning. Mr. G. T. BROWN supported the vote of thanks.

BLACKPOOL LIBRARY COMPETITION.

THE report of Mr. G. H. Willoughby, architect, of Manchester, the assessor to the Blackpool Town Council in the competition for a Carnegie Central Library, has been adopted by that body. It is as follows:—

Gentlemen,—Acting on your instructions, I have made a most careful examination of the whole of the drawings submitted for the above important public building, and herewith have pleasure in laying before you my adjudication on same. Before doing so, I feel called upon to emphasise the remarkable response the architectural profession has shown to your invitation, many able and carefully thought out schemes having been sent in; consequently the difficulty of arriving at an equitable assessment has been greatly increased.

Every design has received my most careful study and investigation, and as a result of my anxious deliberations, extending over many days, I have no hesitation in awarding the set of drawings numbered 41 the honourable position of first place. The author of this design has shown conspicuous ability in successfully dealing with the problem, both from the points of arrangement, construction and design. The scheme is an excellent one, and admirably adapted to the several purposes of your intended structure as set forth in your "Particulars, instructions and conditions of competition."

For a practical working library of the character you contemplate erecting, and providing complete oversight and control to every department, with economy of administration by a limited staff, the general arrangements of the premier

Digitized by Google

design would be exceedingly difficult to improve upon. The author has thoroughly mastered the essential points to be striven for in successfully planning a town library, and the strength and refinement also shown in the internal, as well as external treatment, clearly indicate he is master of his craft. The architectural conception of the elevations is scholarly, dignified, simple and appropriate for execution in brick and stone. Monumental in character, a symmetrical façade is obtained to each street, flanking the main entrance doorway, which is wisely placed (as suggested by you) at the corner of same.

The doorway is made the principal feature of the design, being marked by a low dome, surmounting a handsome colonnade of polished red Aberdeen granite. Ample provision for efficient light and ventilation has been carefully made; also the utilising of all roofing to its utmost capacity should be noted. Taken as a whole, the premier scheme (No. 41) is an economical one. The prices per foot upon which its author has moneyed out the cubical contents ought to be adequate to erect the building (as designed) in a satisfactory manner, and in accordance with your particulars and instructions, due care being exercised in the detailing generally.

Respecting my decision as to the awarding of the second and third premiums, I experience a grave difficulty in advising you. Although many good designs, carefully conceived and conscientiously developed, have been sent in, yet in every scheme certain blemishes and points of weakness are to be found when compared with No. 41.

There are, however, five designs which I have finally chosen, after a most exhaustive scrutiny—viz. Nos. 47, 38, 62, 10, and 104, each of which contains certain merit of its own, either in arrangement or design, or both, coupled with a sincere and earnest effort to faithfully solve the problem. To each of these I have felt called upon to award the commendable position of "equal second." Whilst doing so, there are several most able designs (including Nos. 133 and 117) I have been compelled to disregard consequent on their excessive cubical contents. With your definite instructions as to cost clearly before me—viz. Paragraph No. 3, "The total estimated cost of the building must not under any circumstances exceed the sum of 12,500*l*., and all designs submitted must be prepared on this basis"—I had no alternative but to reluctantly pass over same.

The profession's remarkable response to your invitation (140 designs), which at the lowest estimate I compute have incurred an expenditure of 3,500*l*. to produce, emboldens me, as your assessor, to respectfully suggest that under such exceptional circumstances your Council favourably consider disbursing the whole of the premium money, viz. 100 guineas, equally among the authors of the five designs next in order of merit to the premier one, whose author, I trust, will be appointed architect for the work. It would be a generous act on behalf of your Council, and some return to the competing architects for the enormous amount of labour and money fruitlessly expended by them. My adjudication, therefore, is:—

First—No. 41, to be appointed architect for the work on the terms agreed.

Equal second—Nos. 47, 38, 62, 10, and 104, each to have a premium of 20 guineas.

Nos. 60, 128, 103, 83, 18, 110, 21, 36, and 120, I consider are all worthy of "honourable mention."

I can only affirm that should your Council accept my awards and adopt scheme No. 41 for examination, in my judgment they will secure the best design submitted, and one that most fully and adequately embodies their requirements, taken as a whole.

Remembering the importance of this competition to the profession generally, and that doubtless schemes have been prepared by architects practising in all parts of the kingdom, I would earnestly ask the Council to arrange for the whole of the designs to be publicly exhibited for at least one full week. This would give every competitor the opportunity of personally inspecting same, as well as perusing also a copy of my report, upon which the adjudication has been made. In conclusion, I desire to express my sincere thanks to his Worship the Mayor, the town clerk, and the borough engineer for the admirable arrangements made to assist me in fulfilling my difficult task; also for the absolute privacy and entire immunity from any interference or distraction I enjoyed throughout my somewhat lengthy examination.—Your obedient servant,

GEO. H. WILLOUGHBY.

Parr's Bank Chambers, Manchester, February 1.

First Premium.

41, Messrs. Alex. Cullen, Lochhead & Brown, Brandon Chambers, Hamilton, near Glasgow.

Equal Seconds.

47, S. B. Russell & T. E. Cooper, 11 Gray's Inn Square, W.C.; 38, David Thomson & Christopher Bristow, 7 Cranwich Road, Stamford Hill, London; 62, Cooper & Slater, 13 Richmond Terrace, Blackburn; 10, Charles H. Potter, 20 Cross Street, Manchester; 104, H. R. Gardner, Reigate Road, Leatherhead.

Honourable Mention.

60, C. Harrold Norton, 14 Bedford Row, London; 128, Briggs, Wolstenholme & Thornely, Richmond Terrace, Blackburn; 103, Edward Cratney, High Street East, Wallsend-on-Tyne; 83, Hatchard-Smith & Son, Finsbury Pavement, London; 18, Walter Hanstock & Son, Branch Road, Batley; 110, Herbert Wade, 27 Birley Street, Blackpool; 21, J. Myrtle Smith, 128 Cheyne Walk, Chelsea; 36, F. E. & A. Milne, 136 Wellington Street, Glasgow; 120, Hy. Lord, Deansgate, Manchester.

"Most able Designs."

133, J. H. Mangan, 3 Guildhall Street, Preston; 117, J. B. Thornley, Birley Street, Blackpool.

ROYAL ACADEMY LECTURES—ARCHITECTURE.

THE fourth and last of the series of lectures delivered by Professor Reginald Blomfield, A.R.A., on "Early French Renaissance Architecture," dealt with "Domestic Architecture to the death of Francis I." The Court of Francis I. was rarely in the same place for six consecutive months. The monarch himself built hunting boxes on a grand scale almost promiscuously. La Muette was of brick and stone in six storeys, with a terraced roof for the purpose of allowing the King to watch his hounds at work in the forest. The new manner which was in favour in these and other buildings showed little individuality and no strong impulse in architecture. The workmen were not at home when they tried to follow the instructions of fashionable amateurs. Indeed the master-masons and tradesmen resisted it as far as they dared, and they were in some cases supported by conservative members of the aristocracy. These latter were unwilling to sweep away the buildings with which their family history was connected, and insisted on special portions being preserved in the scheme of remodelling, as at La Rochefoucauld and Chateaubriand. In the reign of Francis the determining factor seems to have been whether or not the noble lord had been in Italy and whether his builder had or had not come in contact with any wandering Italian artist.

Ancy le Franc was considered unique in the history of French Renaissance on account both of its completeness and of its association with Serlio and Primaticcio. But the building has been restored and altered to such an extent that it is now difficult to do justice to its original design; it is a great lump of building seriously handicapped by its site. The age of Francis I. was perhaps the greatest house-building age of France; moreover it was not confined to the great nobles. Next to the monarch, the chief builders were an informal syndicate of wealthy persons who controlled the finances of the kingdom, the first being Semblancay. The ideal of these men did not as a rule rise beyond lavish ornament. The result is that few of these buildings (in spite of their richness of detail) have individuality; not one stands out as the embodiment of a great architectural conception. It is but one more instance of the deep-rooted fallacy that architecture consists in the heaping-up of detail. The French ornamentalist had no idea that sculpture has a definite function in relation to architecture. Nobody as yet was engrained in a tradition of neo-Classic.

There are signs, however, of a real advance towards the end of the reign, for it produced the Hôtel d'Ecoville at Caen. This building is not faultless, but it showed its designer was really an architect, a man who was capable of leaving a wall alone and of relying for effect on rhythm and proportion and refinement of detail rather than on inordinate profusion. But the advance in technical knowledge was not wholly to the good. The tendency of neo-Classic was to ignore materials and to concentrate on abstract design. On the other hand, the same instinct for pure form led French architects of the seventeenth century to skilfully develop the admirable mountainous roof which was purely French in origin and a legacy of mediæval tradition.

Digitized by Google

A careful examination of the buildings erected in France in the first fifty years of the sixteenth century reveals that the positive contribution of that age to architecture was small. The only advance was in house-planning—the fortified house was definitely abandoned. A real advance was made when the designers arrived at the plan which grouped rooms and corridors round a central staircase—the central block at Chambord being an example. But scientific, or rather imaginative, planning did not exist. In this respect French Renaissance fell far behind contemporary architecture in Italy. Judged by those standards which are set by acknowledged masterpieces of the world, the art of Francis I. when tried is found wanting. Yet it had done its work. Out of this welter of experiment there emerged a purer and more masculine art—that splendid version of French neo-Classic which was to reach its full maturity at the end of the seventeenth century.

THE ART OF MR. WALCOT.

By MAX JUDGE.

MR. W. WALCOT'S second exhibition at the Fine Art Society's Rooms in New Bond Street fulfils certain expectations created by the first, held a year ago at the same Gallery, when his architectural studies showed that he possessed the keenest sympathy with the buildings he chose to depict. Then London was his chief theme, and of the many Londons, the London of Portland stone the dominant factor in the scenery of the Metropolis. Primarily London's stone—what Pentelicon was to Athens—Mr. Walcot managed to convey the multitudinous effects wrought upon it by the atmosphere of the city with a reality that brought out the true expression of the most famous buildings of Inigo Jones and Wren and their followers.

The present exhibition is devoted to London and Rome, and perhaps because Italy is not England there is noticeable a distinctly broader touch in his art, his sympathy with architecture, treated though it be almost as landscape, being none the less in evidence notwithstanding. London, too, has by no means exhausted its possibilities for Mr. Walcot, we are gratified to see, and there was nothing in his first collection to beat the river-front of Somerset House, the study in brown of Inigo Jones's vase in Lincoln's Inn Fields, or the drawing of the St. James's Club in Piccadilly—an excellent picture of one of the most picturesque Portland stone fronts in the West End.

Another side of London for which Mr. Walcot shows a decided predilection is also equally evident in this exhibition, and that is a sense of the pictorial in street traffic, and the purely unarchitectural features of a street, such as the shop-signs, lettering and hoardings. There is a drawing of the Strand with the new Gaiety block and the first building to be erected on the London County Council desert beyond, together with the hoardings that have come to be looked upon as permanent landmarks of this thoroughfare. This study will have a greater value when all that vacant spot is forgotten and the Strand once more a humdrum roadway, as in the days of Holywell Street and the "Opera Comique," if perhaps a little better built. And already Mr. Walcot's picture serves to show how effectually the Colonial Government building, rising triumphant on the line of sight, shuts out the legitimate view down the Strand and ruins a large piece of the skyline of the beautiful island church.

Farringdon Market (with St. Bartholomew's Hospital) is another masterly study bringing out the values of the Portland stone; and what we are inclined to regard as the gem of the present exhibition, at least so far as London is concerned, is the little picture of *A Stonemason's Yard, Chelsea*, in which the subject, composition and expression seem symbolical of the spirit that pervades each individual building that has appealed to Mr. Walcot's instincts of what is good.

A word or two of Rome must suffice. There is a large drawing of the *Arch of Severus*, as good as Ruskin's best studies in this field, and two smaller drawings, *The Temple of Minerva* and *The Gardens of the Villa Medicis*, suggest in miniature some of those holiday sketches of Sargent's in which pure sunlight seems to have been caught and fixed with a certainty telling at once of instantaneity and truthfulness of impression.

The Piazza Trevi shows an animated corner of Roman life out of doors, and in this, and in the drawing of Cardinal Rampolla's house more especially, we can seem to detect the characteristic effects of the atmosphere of the Eternal City on those softer building materials no less than our own vivid glimpses of blackened and bleached walls against a rare blue sky on one of London's happy days.

We may point to the drawing of *The Piazza di Spagna* for the excellence of Mr. Walcot's perspective—a little view of the swooping steps with the flower-sellers below. It is full of delicate colour and interesting—the house where Keats died is on the left as you descend the steps. Our last mention must be of *The Steps of St. Peter's, Sunday Morning*, the crowd in front of the portico being more than typical of Mr. Walcot's extraordinary success in dealing with crowds, people enlivened and invigorated with all the qualities of a crowd.

The exhibition is so uncommon in nature that one is bound to remark the peculiar technique by which the artist has gained his effects, and Mr. Walcot would, one is led to think, be very successful in oils; in fact, he seems to miss altogether the characteristics of pure water-colour work as represented by the best work of the English School, and to achieve something distinctly new; something, too—and that is more to the point—fresh and awakening a love of architecture in those who have, to their regret, outgrown an earlier enthusiasm, or forgotten the once all-powerful influence of "Modern Painters" and the "Seven Lamps of Architecture."

THE INFLUENCE OF MATERIALS ON DESIGN IN WOODWORK.

MR. F. W. TROUP, F.R.I.B.A., delivered an interesting lecture at Carpenters' Hall on February 10 on the above subject. After lucidly describing timber houses—those in our own country in what is called "half timber" construction, those in Norway, Switzerland, and other northern countries in pine and, of course, usually "whole timber," i.e. built of solid logs—the lecturer went on to say that when in doubt the designer cannot do better than refer to the old examples in our museums and unrestored buildings, and if you are wise you will take the craftsman into your confidence and you may be able to learn something of him, and at the least you will know what he is equal to, and perhaps find it advisable to modify the design to suit his capabilities, or, better still, leave something for him to modify as the work proceeds. Young architects are told to get to the bench and work with their hands. Now it may seem to them impossible and impracticable to give up the time to acquire even a smattering of half the crafts that go to house-building, but if the young architect does but learn the rudiments of one craft or trade he will find that it gives him an unexpected insight, a kind of instructive knowledge of the others, that will surprise him and reward him for his labour. In designing, above all things avoid being clever merely for the sake of effect. Cleverness is not an art—more often it is mere licence and a want of restraint. Be certain of this, that your best work is not that part in it which you most admire yourself, and you will be safe ruthlessly to cut out that part from the design. Choose to be what critics call commonplace, rather than attempt the clever, the smart, the up-to-date. As a last resource, if in doubt, do what you believe to be right, constructively right and true to the nature of your material, and the result will look right, or at any rate it will be the best that you are capable of.

In conclusion, the lecturer said the design is so completely governed by the material that it is really little more than the resultant of two main forces, the inert material with all its possibilities on the one hand, and on the other the aggressive tools of the craftsman with his infinite capabilities for good or evil—these two forces, the one passive, the other active, brought together by the craftsman and guided partly by his knowledge and experience of what is possible and what is best, and partly by his skill and practice in the use of the tools themselves. These produce the main lines, they effect the assembly or bringing together, the building-up of the whole. That which remains for fancy and imagination to play with is comparatively unimportant. There is indeed a right and a wrong way of letting loose the fancy in carving, painting, or whatever form of gaiety the craftsman allows himself to indulge in, and the right way is always subservient. As soon as indulgence in the fantastic, the *tour-de-force* or attempt to imitate other materials, begin to get the upper hand, so surely does "debased art" become the true and only description of the work. The theatrical, the inessential, the superficial, rules and leads on to the same end that has been described by a great writer as the vile torrent of the Renaissance.

NOTES AND COMMENTS.

THE Japanese are exploiting the combination of volcanic ash with Portland cement, claiming that it not only increases the tensile strength but also produces a mixture more dense than ordinary cement mortar and capable of resisting the percolation of water, thus rendering the combination highly valuable for the construction of reservoirs and for the preservation of iron in reinforced concrete. There can be no doubt that the last word has not yet been said on the influence of various sands on the properties of cement. Experimenters are at work testing the behaviour of cement with many varieties of sand, and vastly different results are obtained from the same cement, so that there is nothing improbable in the claim made on behalf of volcanic ash. As a matter of practical experience we know that the same proportion of ballast, sand, and cement will on one occasion give a waterproof concrete and on another one that leaks like a basket. It is highly probable that the nature of the sand used has very much to do with the difference of result, and architects cannot be too careful in making sure that all the conditions are the same when relying upon their past experience. When one has to deal with poor sand, that is, sand which, by reason of its geological origin, its peculiar composition, or its excessive fineness, gives a low result in a test with cement, the best and cheapest remedy is usually, with concrete at any rate, to increase the proportion of cement. The extra expense is not by any means alarming, for in the cost of concrete the share contributed by the cement is not large, ranging as it does on the average from 7 per cent. in the case of concrete with one part of cement to three of sand and six of ballast, to 14 per cent. with one part of cement to one and a half of sand and three of ballast. Thus an additional amount of cement will be cheaper in Britain than imported volcanic ash from Japan, the Philippines, or even Sicily.

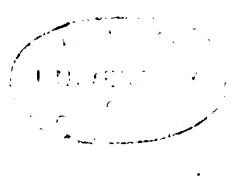
SOME of our unemployed younger members of the architectural profession, so numerous just now, ought to find and seize an opportunity in Canada, where there appears to be a coming boom in building during the present year. We learn that in Winnipeg alone plans are being prepared in the offices of architects of that city for two million dollars worth of work. The young architect who goes from England to Canada cannot, however, hope to succeed unless he has pluck, push, ability, a moderate amount of capital, and a readiness to put his pride in his pocket till he has learnt in a subordinate position to understand the ways of the country. He must not stay in the east and wait for work but push on to the growing cities of the west, and seek for a job. It is also essential that he be an all-round man, well trained in every branch of architectural work—not merely a specialist.

ARCHITECTS frequently have to include in specifications pavings of such a character that leads them to employ asphalte, but this material is not without its disadvantages, chief of which are slipperiness and cost. Both of these may be reduced by the use of an asphaltic macadam, consisting of a mixture of two-thirds crushed stone, varying from $\frac{3}{4}$ inch to $\frac{1}{4}$ inch in size, in approximately equal proportions of $\frac{3}{4}$, $\frac{1}{2}$, and $\frac{1}{4}$ inch, one-sixth of stone screenings, and one-sixth of sand, half coarse and half fine but sharp. This aggregate should be compounded with from 8 to 10 per cent. of an asphaltic cement of low melting point, stability under temperature changes, and small loss under the evaporation test. The aggregate should be heated to a temperature of 300° to 350° Fahr., and mixed at that temperature with the asphaltic cement at similar temperature. The mixture should be laid hot and well rolled with a top dressing of coarse sand.

THERE is no doubt that we are reverting in a sense to the era of cave dwellings, and that the owners of our most up-to-date buildings being restricted to the height they can ascend above ground are endeavouring to cheat the ground rent by burrowing below, and already we have basements and sub-basements. In Chicago, having fully developed the sky-scraper, they are now going into the bowels of the earth, and in the MARSHALL FIELD retail store have constructed a building 151 feet by 161 feet on plan with three storeys below the street level. The basement is a sale-room, the sub-basement a packing-room, and the sub-sub-basement contains the machinery that keeps the establishment going. The lighting of these subterranean caves is easily possible by the help of electricity, but the ventilation is another matter. The system here adopted may be described as a compromise between the plenum and zero-potential, in that while fresh air is supplied by blower fans of centrifugal type, the foul air is exhausted by fans of approximately 20 per cent. less power than the apparatus supplying fresh air. The fresh air is supplied at the top of each room and the foul air extracted at the floor level, an arrangement that is possible where electric light is used, and desirable when fresh air is warmed to the pitch that is considered necessary in the States. The interior volume of each subterranean floor is approximately 380,000 cubic feet, and the air is changed, or rather the apparatus is capable of changing the air, three times an hour in the lowest floor and four times an hour in the other two. The air supply is drawn from the roof level to the sub-sub-basement, where it is water-washed and in winter heated.

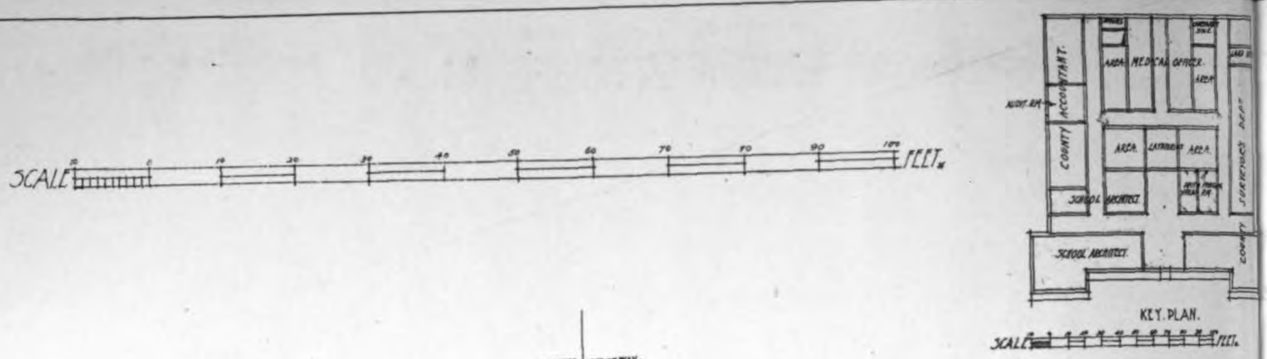
WE are glad to see in a recent number of *Berliner Architekturwelt* and in the supplementary number of that publication, *Moderne Wohnräume*, as well as in the latest issue of our friend ALEXANDER KOCH'S *Innen-Dekoration*, that a more rational spirit characterises the latest work of the New Art in Germany. Simplicity and restraint have to a large extent taken the place of eccentricity and extravagance, the improvement being most marked in the designs for interiors, and particularly furniture, and still somewhat to seek in roof treatment and sky-line. German architecture has always displayed a tendency to forms of roof more curious than beautiful, and one may perhaps regard this as a national trait rather than as a result of the inversion of principles that at first dominated the New Art. The recognition of the beauty of simple form and untortured natural surface in wood and stone compensates, however, for insobriety of sky-line.

ILLUSTRATIONS.

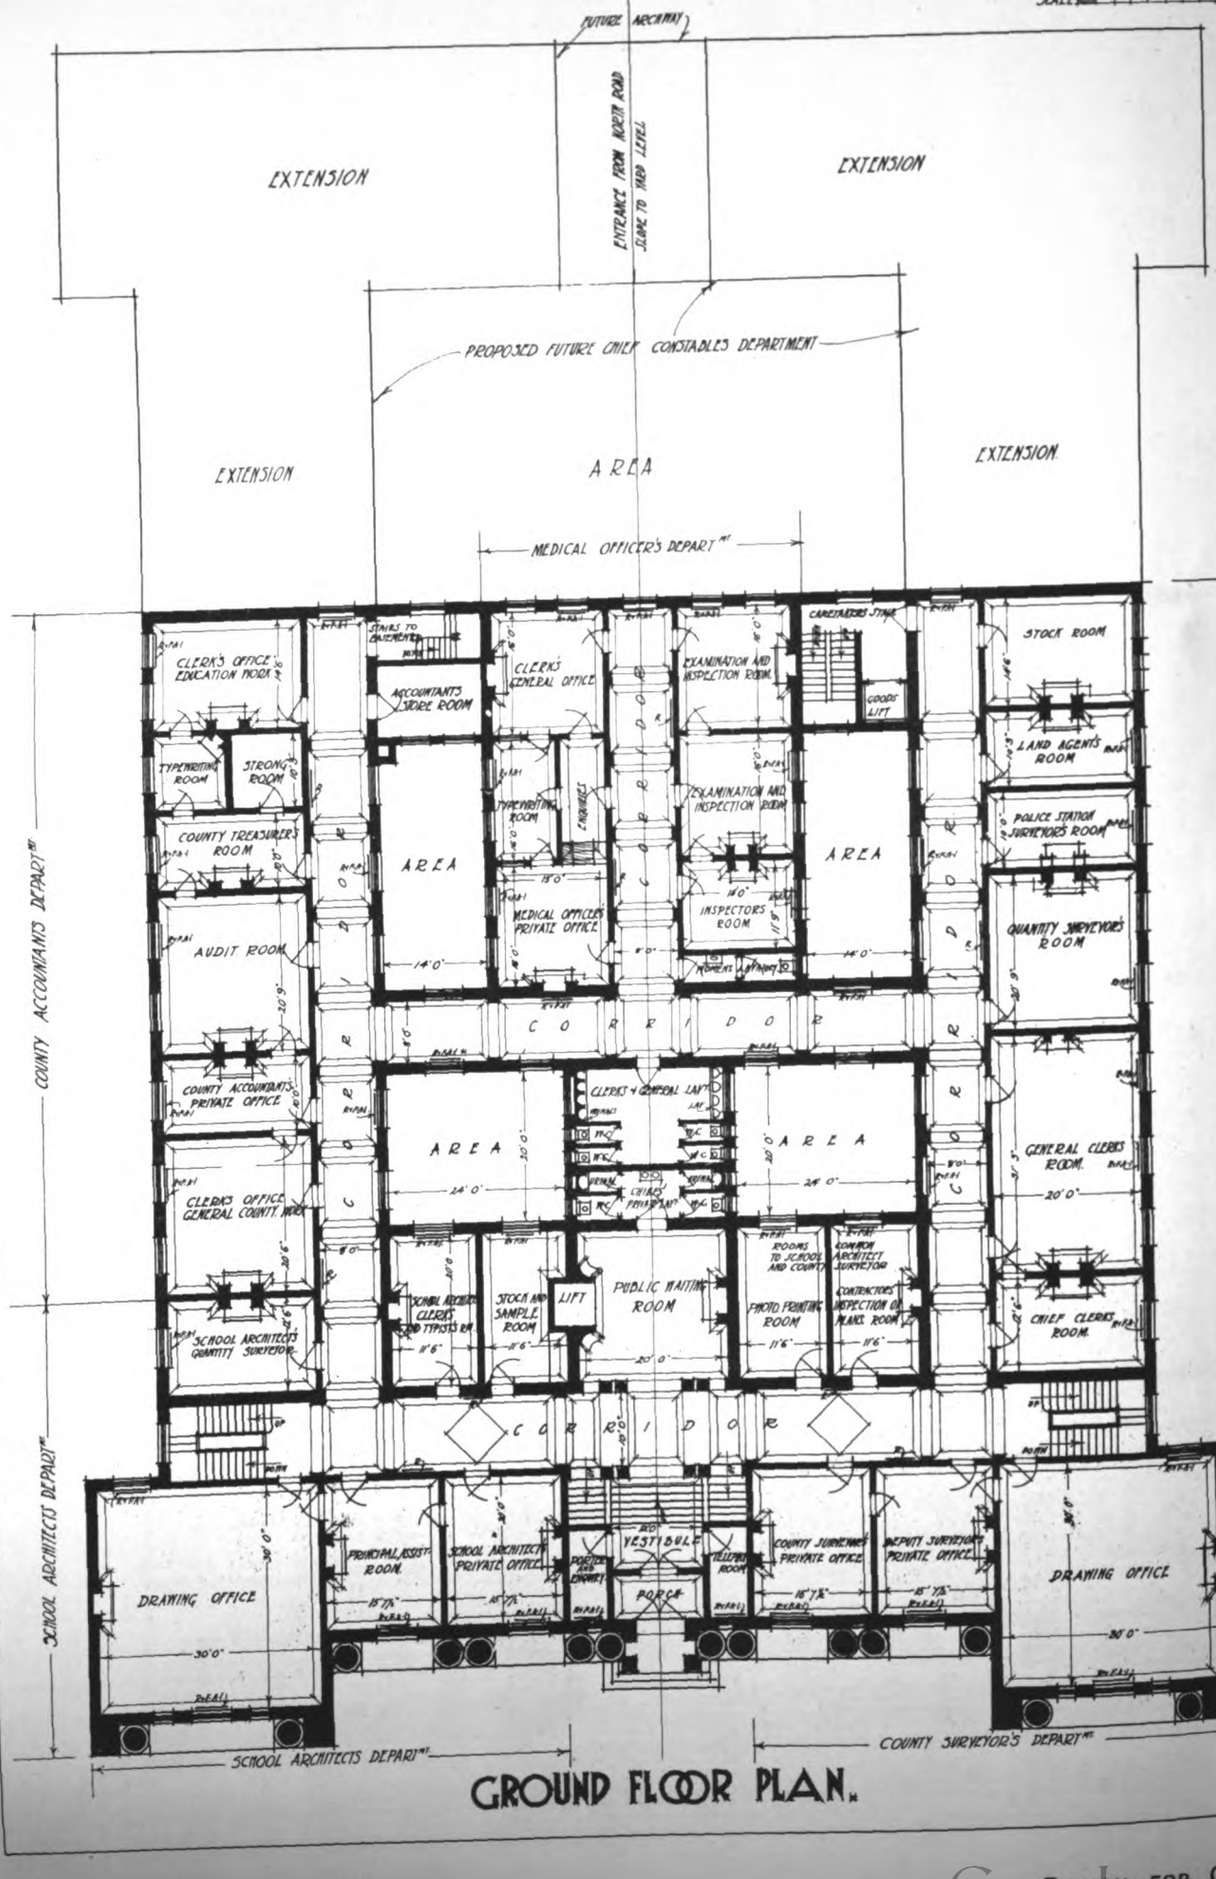


1.—FIRST PREMIATED DESIGN FOR GLAMORGAN COUNTY HALL, CARDIFF.—ELEVATIONS—PLANS.

THE plan is a rectangle, 142 feet by 125 feet, with an open area, almost square, in the centre over the Council chamber and the semicircular ante-room on the ground floor. The Council chamber is approached in a direct line from the main entrance in Central Avenue. The principal elevation has one order to impart an appearance of dignity. On the three other elevations the design depends for effect on its simple masses. Internally the rooms are approached on both floors by corridors, which are arranged around the open area in the centre, thereby forming a plan of the simplest possible description. There were 190 designs submitted in the competition. This design, which was awarded the first premium of 100*l.* by Mr. W. D. CARÖE, the assessor, was submitted by Messrs. E. VINCENT HARRIS & T. A. MOODIE, architects, 8 New Square, Lincoln's Inn, W.C.



2.—DESIGN FOR GLAMORGAN COUNTY HALL, CARDIFF.—ELEVATIONS AND SECTIONS—PLANS.



THE main points in the design for this competition were apparently the position of Council Chamber and County Clerk's Department. It was thought that the first floor was the correct position for Council Chamber, with the County Clerk in close proximity, as a lift for use of infirm members was asked serving all floors. The building was approached from Central Avenue and North Avenue, motors driving straight into the building from North Avenue and depositing at back under Council Chamber near to lift, the elevations being treated in a bold style not to clash with existing buildings. This design was submitted in the above competition by Mr. P. HUBERT KEYES, A.R.I.B.A.

SCHOOLS.*

(Concluded from last week.)

WITH a view of taking more than one class in a room for certain lessons, the provision of a lecture-room is desirable; this the Rules state should accommodate not less than thirty scholars, and may be large enough to hold more; it should be constructed as far as possible on the principle of a theatre, with rising seats. There must be a floor space of not less than 14 square feet per scholar for the first thirty scholars, and 12 feet square for each scholar above that number. This room, as previously stated in the clause relating to class-rooms, "if suitable for class teaching, may be counted as a class-room for not more than thirty scholars."

It is not within the scope of a paper like this to go into details with regard to the various rooms which are needed for what one might call special instruction. I shall therefore only attempt to touch upon points which seem to present matter for discussion. Upon the subject of laboratories the Rules say:—"A physical laboratory should be free from vibration, and for that purpose placed on the ground floor, where possible, and should be capable of being darkened." This instruction with reference to the position of the physical laboratory is fairly definite, and has severely exercised the mind of many a beginner in the planning of schools. But is it of vast importance? If so, why are so many physical laboratories placed on an upper floor? As a matter of fact, the teaching of physics in a secondary school is not of such an advanced character as to demand the extreme freedom from vibration which can only be secured on a ground floor. On the other hand, a point very lightly touched upon in the Rules is the balance-room. These are the words:—"If there is no balance-room a separate place in the laboratory should be assigned for balances." It is, I think, very generally agreed that a balance-room is essential, as it is important the balances should be kept free from the chemical fumes. One of the advantages to be gained by placing the various rooms for special instruction on the upper floor is the improved lighting which can usually be achieved; it is scarcely possible to get too much light in laboratories, and very frequently if these rooms are on an upper floor, light can be obtained from more than one side by judicious planning. If good light is essential in laboratories, it is more so in an art room. The chief function of an art room, if the Rules of the Board are to be interpreted literally, is to defeat the object of its own teaching by utterly spoiling the architectural design of the building in which it is placed. In speaking of the advanced art room, this is what will be found:—"This room should be lighted from the north side by a single large window square at the top to give as much light as possible."

If one is lucky in the matter of aspect, one may be able to get this single large window square at the top, facing an area, or concealed from view by roofs; but if the aspect is not favourable, and one of your important elevations faces north, you will need the skill of a Michel Angelo to make the type of window an art mistress sighs for harmonise with the scale of your building.

And is this north light in such abundance the one and only light which will enable the scholars in a secondary school to benefit by the teaching given to each class for an average of eighty minutes per class per week? I put the following question to the headmaster of one of the first art schools in the kingdom:—"From which quarter would you prefer the light of an art room?" His reply was:—"I don't much care from what quarter it comes so long as I can get plenty of it, and still have enough if I have to shut out some when the sun gets in. I prefer some sun, as I may need a class to study the effects of sunshine on various objects; flowers and foliage under sunshine have new revelations for us." A north light for a studio painter of large pictures is, I believe, a *sine quâ non*, but a secondary school is not dealing with such, and I question whether sacrifices in the design of a building should be demanded where the need does not really exist. For all practical purposes, in my opinion, a well-lighted class-room with ordinary windows, possibly from one side and one end, or two sides, will serve admirably for the kind of art teaching which is given in a secondary school.

A point with regard to dining-halls and the kitchens in connection with them, which is perhaps worthy of note, is the desirability of providing a separate entrance for trades-people; this will generally, I think, be found a great convenience. A library in a secondary school, although not insisted upon by the Board, is certainly a very desirable attribute. As far more time is spent by teachers in secondary schools in preparation work, correcting papers, &c., than is the case in elementary schools, larger and more comfortable rooms for their use will need to be provided, and the headmaster will require a really spacious room, as books and papers with which he has to deal will occupy a lot of space.

In cloak-rooms twice the length of hanging space is required as compared with elementary schools, and in neither should lavatory basins be placed in the cloak-room.

A point which will materially influence the architectural treatment of the elevations is the large area of window lighting required by the Rules, which state that "the area of window glass should approximate to one-fifth the area of the floor space in rooms used for teaching, and in other rooms not less than one-eighth." I doubt if so much is often given or really necessary. It is hardly necessary to mention that light is required to come to the left-hand side of the scholars. A point of importance is emphasised in the following clause:—"Unless the top of the windows be more than 12 feet above the floor the plan should show no space more than 20 feet from the window wall in any room used for teaching."

With regard to sanitary accommodation, it is suggested that the girls' offices should be in the main building, and those for boys completely disconnected and at a short distance from the school. In a girls' school some headmistresses advocate the distribution of a small number of water-closets on the various floors in addition to a main block of offices. Automatic flushing for closets is undesirable, and each closet should be fitted with its own apparatus. In elementary schools an automatic flushing system is almost universally, I think, adopted, although I understand that many educationalists advocate the employment of an independent flushing apparatus, with a view of inculcating habits of decency from the earliest moment. In one case I know of where efforts in this direction were made in an elementary school, the result was not satisfactory, and an automatic system had ultimately to be installed.

If the planning of elementary and secondary schools does not present many points for great differences of opinion upon general principles, and in the main I think it does not, one has not far to seek for matter to provide quite adequate discussion. If I thought any heating engineers were present, I do not know whether I should have the courage to mention the word "ventilation" for fear of the discussion I might provoke. I want, however, to touch upon it from the point of view of the architect, and not of the expert. Of its importance there can be no question, since the only real departure from accepted methods of school planning owes its origin to a desire for the natural system of ventilation. I refer, of course, to the Staffordshire school, so well known to all. The question at issue appears to be whether efficient ventilation can be secured for comparatively crowded rooms without the employment of mechanical agency.

Dr. Reid, the county medical officer for Staffordshire, maintains it can; others that it cannot. Whether each mean the same thing by efficient ventilation is open to doubt, if we define it as "an adequate supply of fresh air of a proper temperature, admitted in such a manner as not to cause a perceptible draught." Sufficient movement to obtain a change of the air in a room is the main essential in any system of ventilation, and whatever means may be employed must be directed to this end.

In the case of the Staffordshire schools the movement of the atmosphere is relied upon to effect the necessary change, and a through draught is facilitated by means of open windows on both sides of the rooms, in addition to a ventilation grating at the back of the heating radiators; the windows are so arranged with a hinged, glazed screen at the base, which it is claimed gives an upward direction to the entering air; and the same arrangement serves for exhausting the vitiated air, the window on either side acting as an inlet or outlet, according to the direction of the wind. Time will not permit me to go into all the claims made by Dr. Reid in support of the type of plan he advocates; his main contention, however, to quote from his report, is:—"That if the central hall type of school is to be maintained, it is only by employing mechanical means that anything approaching adequate ventilation can be obtained, and even with such means the result is not satisfactory; and that the solution of the question is to be found in the plan which is described as the Staffordshire type." Whether such a plan as this is, as Dr. Reid claims, "quite compatible with educa-

* A paper by Mr. H. T. Buckland, read at the last meeting of the Architectural Association.

Digitized by Google

tional requirements," is open to question. One central hall for three departments, of necessity, as was pointed out to me by a prominent educationalist, does away with the morning assembly of two of the departments, and the need for a head master and mistress as such almost disappears if their personal intercourse with the children is reduced to a minimum. It is open to discussion whether such a sacrifice is worth making on the assumption that a satisfactory method of ventilation cannot be secured, even by mechanical means, in a school planned with the class-rooms round a central hall. One is justified in assuming that Dr. Reid is only familiar with one method of mechanical ventilation, viz. the "Plenum" system, as his report at the outset remarks:—"All systems of mechanical ventilation, moreover, present a shocking object-lesson to the children from their inherent need for having all windows permanently closed."

So far as the "Plenum" system is concerned this is true, and the argument is a weighty one against its use. Personally I have found a majority of the teachers in "Plenum" ventilated schools adverse to it, and this is particularly the case with lady teachers.

Bearing upon this question, the opinion of Mr. Felix Clay, architect to the Department, as recently given in evidence before a consultative committee appointed by the Board of Education, will be of interest. "The 'Plenum' system," he said, "has many strong supporters, who are able to show that, chemically, a fairly pure atmosphere is maintained by it." Mr. Clay, however, was strongly adverse to its use for school purposes. "In the 'Plenum' system warm air is introduced under pressure into the upper part of the room; this, being at a higher temperature than that already in the room, spreads over the ceiling, and, being under pressure, produces a gradual downward movement, passing out of the room at the floor level. Certain objections to the system are the warming of the rooms by hot air only; this requires raising the incoming air to a temperature that seems to destroy some of its invigorating qualities and produces a somewhat enervating effect. Perhaps the chief objection is that, for the proper working of the system, it is absolutely necessary to keep the windows closed, and, in order to insure this, the windows are not as a rule made to open; this has a very serious disadvantage in accustoming the children to sit in rooms with the windows shut." Any system which meets with such strong condemnation from different quarters will find it hard, I think, to endure. One has not far, however, to seek for an alternative, which appears to provide the advantages of a natural system with open windows, without necessitating the abandonment of the generally approved central hall type of plan; a system of mechanical extraction will, I think, be found to meet the case. Such a system is practically the reverse of the "Plenum"—the foul air being sucked out and the fresh air drawn in, instead of the fresh air being pushed in, forcing the foul air out. This system was employed in the secondary and elementary schools at Rotton Park. In that case, fresh air is admitted to the various rooms by means of gratings at the back of the radiators and through the windows, in which the lower portions open as hoppers and the upper casements swing; the foul air is drawn from the rooms through a grating fixed in a riser extending the whole width of each class-room; this riser is in front of a duct which communicates with the main underground ducts all running to the extract tower, at the base of which are fixed two large centrifugal fans driven by electricity. In addition to the grating at the floor level there is a small grating near the ceiling, at the head of a flue which communicates also with the underground ducts; this is for the purpose of drawing off the extra heat and fumes arising from the gas lighting. The whole of the windows may be kept wide open if required. No chemical tests have been made of the air in these schools, but so far as the evidence of the senses and the testimony of the teachers is concerned, I have every reason to be satisfied that it is such that both teachers and students find it stimulating and comfortable to work in. It certainly has the merit of being almost entirely under control. Doubtless satisfactory results have elsewhere been achieved by similar methods.

Of the methods of heating at one's disposal we now have many. Low-pressure hot water is still so dear to the hearts of many that one is loth to disparage an old friend; but it will, I think, generally be found difficult to obtain really adequate heating in conjunction with a proper air supply without resorting to some more rapid system of circulation.

The various systems of forced hot-water circulation, although differing in method, all have the same end in view, viz. acceleration, and it seems obvious that the oftener you pass the water through your boiler the warmer you are likely to keep it, assuming your boiler can supply the requisite heat.

Atmospheric steam has been largely used of late years, and my experience of it in large buildings is certainly favourable, but my impression is that the tendency among heating engineers is distinctly in the direction of accelerated hot-water systems.

A weighty argument always advanced by the advocate of ventilation by natural as compared with mechanical means is the question of cost—not only first cost, but also cost of maintenance. Ventilating engineers may have some reply to this; I have none, except that if efficiency is required it will need to be paid for. As regards the question of first cost, Mr. Clay, in the evidence already quoted, estimated the cost of installing the "Plenum" system at from 1,500*l.* to 2,000*l.* in a school of 1,000. I am inclined to agree with this, if the figures quoted represent the cost over and above a natural system—i.e. to say I consider the "Plenum" system adds from 30*s.* to 2*l.* per child to the cost of a school for 1,000 children. A system of mechanical extraction such as I have described adds less, as the size of the ducts does not require to be so great or the finish so good as in the case of the "Plenum." This naturally brings us to the whole question of cost of school buildings.

My own experience is that an elementary school cannot be built for a reasonable number—say, from 750 to 1,050—at less than 10*l.* per head, and to achieve this the site must be level and have a good foundation. The school at Acocks Green, which was shown, will cost, I understand from the architect, rather less—probably not more than 9*l.* 15*s.*; but this is an exceptionally large school and has classes each for sixty children. One education authority in the Midlands which has promoted several recent competitions allows 14*l.* per head; for this, I think, a very decent school may be expected if no mechanical system of ventilation is required. Of course a good deal depends upon whether a school is in two or three departments. Ten pounds per head for a three-department school is very low.

The Staffordshire schools in three departments, but with only the one central hall, cost 10*l.* 10*s.* 4*d.* per head.

Of "Plenum" ventilated schools I know of one in two departments which cost 15*l.* per head. A really well-built school with three departments and three central halls, a mechanical system of ventilation, and some regard to an architectural treatment in design and materials, cannot, I think, be built for much less than 17*l.* per head. For that amount boundary walls, 14 inches thick, or walls and railings all round the site, and a caretaker's house, may be expected to be included.

These figures represent prices per foot cube, ranging from 5½*d.* to 7*d.*, and as boundary walls and play-grounds are included in the prices mentioned per head, these items have to be priced separately and added in making up an estimate. In discussing the cost of secondary schools, I find myself at variance with the accepted method of pricing at per head. In elementary schools, given a certain number, there will not be much variation in the size and number of the rooms; but in a secondary school, although the number of class-rooms and children accommodated may be the same, the rooms for what I have called special instruction may vary considerably. Education authorities seem to lose sight of this fact, and in some cases invite plans in competition, stipulating for extra large laboratories and art rooms, swimming-baths, and many other things which do not form part of another school upon which they base their price per head. Thirty-five pounds is a favourite figure to quote, but a quite insufficient one unless the accommodation in laboratories, art rooms, dining-rooms, gymnasium, &c., is kept within modest limits.

Of the plans I have shown, the school at Bishop Auckland, by Mr. Reynolds, is estimated to cost 15,000*l.*; and for the one at Bromley, by Mr. Burke Downing, the sum of 8,000*l.* was mentioned in the conditions of competition. The accepted estimate for the schools at Barnsley was 18,672*l.* Of the schools at Rotton Park I am unable to separate the cost of the secondary portion, as this and the elementary school were all in one contract. From 6*d.* to 7*d.* per foot cube will, I think, be found reasonable working figures, with further allowance for playgrounds and boundary walls.

My paper, I regret, has run to a far greater length than I originally intended, but my subject must be my apology, and it adds to my regret that I have treated it, I cannot help feeling, somewhat inadequately.

Mr. F. J. OSBORNE SMITH proposed a vote of thanks to the author of the paper, and said that many of the points raised in it were probably new to those architects who practised in London, since they were not accustomed to the single-storey schools. They had seen illustrations on the screen of schools in which the children appeared to be packed rather closely together, and in one class of sixty he felt some pity for the scholars when he heard the whole of the ventilation was on the "Plenum" system. He was bound to say that he had not found one school ventilated in a satisfactory manner, but he wished to mention that he considered the question from the children's health point of view. A short time ago there was an International Congress held on school hygiene, and Sir Lauder Brunton then stated that defective ventilation had a most exhausting effect upon children, and predisposed them to succumb to any active disease by which they were likely to be attacked. They knew also that when adults had to live and work in closely packed areas they became debilitated and sickly, and hence it was vitally important that their children should at school work under the most favourable conditions. In towns, therefore, special attention should be given to ensure that children enjoyed fresh air and sunshine. London and Birmingham evidently were parallel cases as regards restriction of sites, and in Birmingham the authorities had adopted the wise plan of single-storey buildings. The beneficial results of open-air schools proved there was a necessity, especially in large towns, for introducing very much more air into the interior of school buildings than architects as a rule made provision for. The Staffordshire type were admirable examples in this respect. The matter of ventilation was, however, largely left in the hands of teachers, and although special systems and arrangements might be introduced into a building, a great deal depended on their common sense for its ultimate efficiency. For sunshine he would agree with the paper that the south-east aspect was best, and that was an important point in planning. No doubt aspect as regarded the admittance of light was a good deal of it sentiment, but doctors who had studied the subject condemned working in shadow as injurious to eyesight. There were always conflicting views, however, and it seemed best, therefore, for architects to confine themselves to the practical part of school planning, which was to safeguard the health of the children.

Mr. OWEN FLEMING seconded the vote of thanks, and spoke of the movement towards the establishment of open-air schools around London and the encouragement the County Council had received. For ordinary school buildings he suggested there was a limit to the development of the open-air idea in the class-rooms. In the large manufacturing towns in the North it would mean a new class of school altogether. If the windows of buildings in some of those towns were kept open all kinds of impurities would enter. There was another development which might change school planning within the next ten years, and that was the encouragement given to physical training. In Germany and Sweden, the pioneers of educational work, every school had a gymnasium, and gradually the importance of physical training in schools was being recognised in England, and the result would probably lead to an adoption of the foreign arrangement, and they as architects should be ready to meet it.

Mr. T. J. Bailey contributed some notes on the paper, which in his absence were read by the HON. SECRETARY. Mr. Buckland, he said, only deals with two kinds of school, the ordinary elementary type and the secondary school. To make the subject complete I should have expected some reference, at any rate, to be made to the higher elementary type on the one hand, and the schools for mentally and physically defective, of which there are several requirements, on the other. To take his remarks on the elementary school, he naturally begins with the site; as his remarks evidently only refer to large schools in towns, it is manifest that the educational body has very little choice. It is not always possible even to obtain the 30 feet of unbuilt-upon playground space which is regarded as a minimum by the Code of the Board of Education. In London, at any rate, considerations of rehousing obligations operate largely in the choice of a site. In the paper I read at the R.I.B.A. some years ago I gave my observations on this subject, and can only repeat that the only ideal site is to be obtained in a not altogether built-upon suburb. No doubt the Board of Education is right in laying down the axiom that a three-storey type should not be followed if space allows for the buildings to be one or two storeys high. The question of the desirability of a central hall has gone beyond the line of argument, and also, I am glad to say, has the question of whether each department should have its central hall or whether there should be one common to two or three departments. As the hall takes the place of a corridor, giving access to the various rooms, it is obvious that great confusion would ensue if the hall was used by another department than that to which it was attached, and, if built as a separate block, each department would need corridors and connections with the hall, thus rendering the cost prohibitive. In a school of the size referred to in the paper—viz. 1,000 to 1,200 children—the point raised as to its being built as a two-department school—infants and mixed—is worth notice. It would not do to provide more than about 380 infants, and this would give a mixed department of 700 or 800—manifestly too large. The mixed department would therefore have to be divided into two, senior and junior, possibly under one head teacher—preferably not. In large towns the position of the school with regard to the social position of the families supplying the children would probably determine the question of mixed or separate departments—the lower the grade, the more danger in mixing. With regard to the sizes of the class-rooms, the lecturer appears to favour classes of from fifty to sixty. In the paper I referred to I dealt with that subject, and am glad to be able to say that all new schools and alterations to old ones in London under the County Council have a unit of forty for the class-rooms, any variation of that being in favour of a smaller number, thirty or thirty-five in the graded departments and not exceeding fifty in the infants; and I would here emphasise my view, expressed at that time, that no seats should be more than 20 feet from the window wall, and I wish the Code would be altered accordingly; for elementary schools it is equally as important as secondary. Mr. Buckland makes no reference to the desirability of providing any other rooms for teaching purposes than the ordinary class-rooms. In my opinion and with the experience I have gained in building the schools of London for twenty-five years, I consider it very desirable that there should be a room for general science—not advanced work—and also a room for art teaching in the boys' departments and rooms for teaching domestic subjects in the girls' departments, and I would have these attached to all schools; also a room apart from the main building in the boys' department for manual training work in wood or metal, or both. I am afraid the remarks on secondary schools do not give much guide to either the requirements or the points of planning, but I would remark concerning them:—(1) The number to be accommodated. Mr. Buckland knows of no recent secondary school which accommodates more than 400 in one department. I am building five secondary schools for girls in London, accommodating upwards of 500 in each, and I certainly do not agree with him that a central hall is not the best arrangement; with nine class-rooms or more on a floor it is surely better that they should discharge into a large hall than into corridors, and it is manifestly the cheapest arrangement for building, and I can answer for it that there is not only no inconvenience, but it is appreciated. There are many requirements in secondary schools which are not touched upon, but the variety of subjects taught and the needs in such an educational establishment need more than a passing reference. As regards the number of departments in a secondary school, it is best that, in large towns, they should be built as separate schools; of course, in country districts combined schools may be desirable, having regard to the smaller numbers to be provided for. Finally, and the only matter the lecturer touches upon in detail—on the question of ventilation—the remarks are all a criticism of the "Plenum" system, and, as I understand it, a condemnation of it. This I cannot agree with. In my opinion a really good modern installation on this type is the best that can be had, but there are so many prejudices against it that public bodies hesitate to adopt it on this account. I have installed it in five or six cases some years ago with great success. I have also installed it where it has been continually complained of. If I were to instal it in a building now I would only have it in operation in the winter, leaving the open windows to ventilate in the summer; but the extra cost on the building for ducts and flues renders the cost prohibitive where there is a desire to keep down the cost of a building to the lowest point. Experts favouring both systems would argue the respective merits for a week, and would probably leave the hearers confused and unconvinced. I can only speak from my own experience. A head teacher told me the other day in a school where the "Plenum" system was installed ten years ago that in foggy and frosty weather they are practically in the Riviera, and I have never heard any complaints from that school that the

Digitized by Google

windows could not be opened in the summer. As regards the system of warming by low-pressure hot water as compared with steam, it is well to remember that the latter probably means the employment of an engineer for working it in the winter, as it is too dangerous to entrust to the ordinary schoolkeeper, with his multifarious duties about the school, whereas the former can easily be attended to by him. In his remarks on sanitary accommodation, Mr. Buckland refers to automatic flushing. This means troughs, which are pretty universally condemned by the faculty in these days. Besides, all towns have their sanitary by-laws, and I doubt if any at the present time would approve these, certainly not in London; it is surprising news to me that even in a single case independent flushing "was not satisfactory, and an automatic system had ultimately to be installed." It would be interesting to hear where this occurred. The reverse is my experience, and is the cause of constant disputes with Borough Councils in the case of old schools which are working satisfactorily. The general remarks touching lighting, desking, &c., are truisms which need no comment, but I would like to place on record my opinion that the requirements of the Code as to the areas of central halls—viz. a minimum of 6 feet per scholar in secondary schools and a maximum of 4 feet in elementary schools—is incomprehensible, especially considering that in a properly equipped secondary school there is a gymnasium and dining-room in addition.

Mr. BUCKLAND, in reply to the vote of thanks, said he could not have covered all the points which Mr. Bailey had wished him to do within the limits of an evening's paper. The question of the desirability of providing a central hall had not, he thought, gone beyond the line of argument, and so far as secondary schools, he was certain it had not. With regard to the "Plenum" system, he had not, he said, expressed a personal view, but merely the opinions of others, though he could say he had never found a school ventilated on that system the air of which reminded him of the Riviera.

MANCHESTER ROYAL INFIRMARY.*

IN order that there may be no misunderstanding as to the scope of my subject, I wish to make it clear that this will be treated only from the points of view with which the Sanitary Institute is more particularly concerned. It may not, however, be out of place to say that the architectural conception of the design has been to so plan the buildings that the respective parts adapt themselves to the various purposes for which they are required, and that in such a way that all may be seen to be naturally and harmoniously related; the many integral parts emphasising the unity of the whole.

The principles on which the design is based are divided under three heads:—Hygienic, Sanatory and Æsthetic.

Let us first consider how hygienic conditions prevail in the design of the New Royal Infirmary, and begin with the essential of:—

Fresh air.—Attention should be drawn to the block plan of the buildings (see *The Architect*, January 11, 1907. It will be seen that the relation of the whole to what may be termed the main air routes are that, on the west Oxford Road runs past a frontage of about 508 feet of the site; on the north, Nelson Street passes a frontage of 268 feet; on the south, York Place skirts a frontage of 512 feet; on the east, another street runs up to the boundary. Lying within these air channels is the site of about thirteen acres of land, and on this site are in all forty-eight buildings of various kinds. Every building is kept detached from every other so that air currents pass all round and over, and, in the case of the medical and surgical pavilions, under each, and considerable areas of grass and paved spaces left open on the north and south are reservoirs of air. By means of the many cross routes of varying breadth currents are induced. There is not a single enclosed court or area in the whole of the hospital.

The distance between each pair of pavilions is about 60 feet, and many buildings are separated by greater distances. Judged by the population standard, the Infirmary when full will not have more than about seventy to the acre. All the buildings are necessarily connected together for administrative purposes, but the connecting corridors are all partially enclosed on both sides on all storeys, and are so designed that the apex of the roof of each is well down below the floor of the upper storey, allowing the air to pass through in an uninterrupted course. The roofs are of glass, with wide projecting eaves over the passage way, and these projections, with the iron close balustrade, effectually protect the pedestrian from normally inclement weather. The communication of fire or smoke from one building to another is impossible, as any flames escaping from a building would break the glass roof and isolate a fire.

The air around the Infirmary, although sometimes—perhaps generally—charged with smoke or carbon, is practically pure in that judged by the carbon-dioxide test it contains only about five parts per 10,000 as against three in the mountain wilds of Scotland, and the currents passing round every side of all the buildings are admitted directly into every room, ward, or other compartment, by means not only of windows, but of other openings which, if windows be closed, will give an abundant supply of air for every occupant.

Pure Water.—It is now a good many years ago that a crusade against storage cisterns in weekly tenement houses was started, and the external standpipe off the main for common use became an institution. Inconvenience sometimes arose in case of a burst main or a sudden frost, but another standpipe was available at no great distance. In a large hospital the loss of a water supply from either cause would be a calamity, and so cisterns of large capacity were considered a necessity, to provide not only for current use, but for storage during a reasonable period to cover the maximum possible stoppage of public supply. In the Infirmary, however, we tried a better way, and obtained supplies from three separate mains coming from different sources. We connected all three to a large ring main in the warmed subway within the hospital. The concurrent failure of all three supplies is practically an impossibility. There are no cisterns at all for any of the ordinary purposes, and every sink, lavatory, bath, water-closet, fire service, standpipe, &c., is supplied directly from the main with fresh and pure water. This incidentally saved the cost of all cisterns, service pipes and their fittings; all ball-valves and overflows, safes and cistern housing; as well as the maintenance of all and the periodical cleaning out.

In this connection another sanitary arrangement may here be referred to. The overhead flushing cistern for w.c.'s has been abolished. The cistern of white glazed ware with glazed lid, has been placed on the closet under the window, and the apparatus is actuated by the door. Instead, however, of the usual iron rod and lever mechanism, a wired tube is substituted. The mechanism ensures that the flush shall occur only on the alternate opening of the door, saving 50 per cent. of water as compared with the old system. It should be stated that all pipes used for cold water are either cast-iron or tin-lined pipes, and for hot water cast-iron, copper, or nickel pipes.

Sunlight.—Every pavilion has its axis practically north and south. Every large ward has windows all round three sides—east, south and west. The distance apart of the two-storeyed pavilions, between the large wards of each, is about twice the height from the lowest window sills, so that direct rays enter the lowest window when the sun is 24° above the horizon; and where there are three-storeyed pavilions, in the same rank, the diminution on *one side* only, as compared with two-storeyed wards, is at the equinox only a loss of one and a third hour. One three-storeyed ward has all the sun's rays when it is 5° above the horizon. The out-patients' department is isolated, and the sun's direct rays enter every part when the luminary is 7° above the horizon on the east, and 24° on the west. The septic pavilion is so isolated as to have all the sun's rays. Every room in the administration and teaching blocks has direct sunlight.

The Nurses' Home is broadly a U-shaped block open to the south, with horns on the east, and every room on ten of its eleven faces has direct sunlight. The laundry is detached, and open to almost every ray of sunlight, and the workshops face west. The kitchen department has direct sunlight on every part, except to the larders which all face north. I have now only to mention the theatres. These are each units of seven rooms. The theatre proper intentionally faces north, but every other room has direct sunlight.

Drainage.—We now come to the last branch of hygiene: the removal of sewage and other deleterious matter. The problem in so large a place as the Infirmary is akin to that of a village within a town. We have within the curtilage 4⅓ miles of drains. Two main drains run east and west into the Oxford Road sewer, and one into the York Place sewer.

* Abstract of a paper entitled "Manchester Royal Infirmary from the Hygienic, Sanatory and Æsthetic Points of View," by Edwin T. Hall, V-P.R.I.B.A. (Member of Council), read at sessional meeting of the Royal Sanitary Institute, Manchester.

Digitized by Google

These are efficiently disconnected from the public sewers, and are all ventilated in such a way that it is impossible for sewer gas to collect. They are divided into sections with inlet and outlet ventilators to each, and some sections have special shafts fitted with hydraulic fans for air extraction. Every building has its complete system of drainage disconnected from the main drains, all separately ventilated, so that nothing can be communicated underground from one to another. The manholes at frequent intervals are specially made of the same glazed ware as the drain-pipes. The bottom sections, with all the various branches at the required angles, are in one piece, each having been made from a separate drawing. The branches are about three-quarter pipes in sections, and the benchings have steep slopes. Every drain can be swept between two manholes. All gullies from sinks, lavatories, and baths are taken into the soil drains and are ventilated. The rain-water drains are separate from those for soil, and are disconnected from the soil manhole, into which they ultimately discharge. It is a usual practice to put flushing tanks at the head of soil drains, but the expense of water is great, and this expense has been obviated here by inserting on the rain main drain just before its entry into the soil manhole an automatic flushing tank, so that instead of a small and regular stream trickling through, the rain-water discharges in volume and at considerable velocity, and so scours the soil drain. All manholes in rain drains have gridiron covers, so that the pipes are always open to be sweetened by fresh air.

Soil pipes are of lead, and all branches are of the same internal diameter as the traps of closets, while every one of the traps is separately ventilated. Lavatory, bath and sink stack-pipes are carried up above the roofs as ventilators.

Smoke abatement.—In the Nurses' Home, a building of about 250 rooms, there are only coal fireplaces in the sitting rooms, about a dozen in all; and there are none in the general servants' bedrooms in the centre block, or in the men servants' bedrooms. In the large teaching block in Oxford Road there are only about ten. The general heating in all these buildings is by hot water.

Heating.—Until recent years the method of heating a large congeries of buildings such as this was by placing a calorifier, supplied by live steam, in each building, the circulation within the building being by gravitation. The expense of this in plant and maintenance and in steam is great, and the labour involved in the supervision of such mechanical calorifiers at a distance is considerable.

Some ten years ago I introduced a new system into a large hospital by which the whole heating was done by one calorifier adjoining the steam boiler house under the eye of the engineer, and pumping the circulation all round the buildings.

This system has been adopted in the new Infirmary. From the calorifier duplicate ring mains run in reverse directions all round the subways. Off each of these subsidiary circulations are taken which supply half the radiators in each building, so that in the very rare occurrence, on a low pressure system, of a broken joint, no building can be without heat at any time. With a broken joint the circulation in the affected ring main is not stopped, but by means of three way valves the water is merely shunted on to the other main while the repair is made.

The supply of all hot water to baths, lavatories, sinks, &c., is on exactly the same system from an adjacent calorifier. The steam mains on the boilers are in duplicate. The total length of water and steam pipes in the buildings is about nine miles. A considerable economy has also been effected by collecting all exhaust steam and condensed water, filtering and re-using both either in the calorifiers or in the boilers.

Artificial Lighting, &c.—The electric supply for lighting is taken from two separate Corporation stations, the light in each pavilion and theatre being divided between the two sources of supply. The same power is used for lifts, machinery motors, sewing machines, refrigerators, mincing and coffee grinding, and other culinary apparatus, for ventilation, and for other purposes. In every building we have also placed emergency gaslights, and it may be added that all gas for these, for cooking, &c., is taken off two separate Corporation mains and connected to a ring main as before described.

We next come to the second or Sanatory branch of our subject, or that pertaining to therapeutics—the healing of the sick. The province of architects is to provide means for the utilisation of hygienic conditions to assist in restoration to health.

The Pavilions.—Having sketched the hygienic environment, it becomes important to show what are the buildings provided and how they are designed for sanatory purposes. A description of one pavilion will be sufficient for all.

This is detached, and each floor is entered from the north, whence a wide corridor of glazed brickwork leads to the main ward. On either side of the corridor are small wards, a kitchen, and various stores. By large opening fanlights above the doors, reaching to the ceiling, and similar fans over the external windows, cross currents are obtained for constant æration of the corridors. The large ward is a parallelogram giving about 130 feet of floor area, and about 1,800 cubic feet to each bed. Its floor is of linoleum, its walls painted and varnished. There are no ledges, and all angles are concave. All doors are of polished wainscot with sides in plain unpanelled sheets. It has windows all along both the east and west sides and at the south end. The ratio of window to floor area is one to four.

All windows are designed to open to their full extent. Every window has, in addition to a pair of sashes, a fanlight reaching to the ceiling, opening inwards with guarded cheeks, and adjustable to suit the velocity of the wind.

To maintain the purity of the air inside the wards, all gas lighting, except emergency fittings, has been excluded.

The open window is sometimes not possible, and provision should be made for an adequate supply of fresh air even if all windows be closed. The provision here made is for fresh air to enter at the back of the hot water radiators under the windows in such volume that at a low velocity the atmosphere of the room may be changed three times per hour. The admission is controlled by a valve to regulate the volume. At a higher velocity this change may be increased in frequency at discretion. The air passes over the radiator, so that the ward may be heated to a temperature of 60°.

For extraction there are two shafts from every large ward fitted with electric fans, which even on the stillest of days ensure the passage of air through the ward. There is one fireplace, all of faience, at the south end for cheerfulness.

At the same extremity of the ward are the detached sanitary towers, the one containing bath, &c., the other w.c.'s and sink room. Both towers are heated. For bathing a glazed ware bath is provided of special design, with a wide flat anti-splash rim on which a patient may sit. All baths and lavatories are discharged into open channels, and insanitary horizontal pipes are avoided. Provision is made for bedpans to be kept warm, ready for use.

For the quiet of patients the floors are sound-proofed by hollow floors and through wind currents.

Freedom from anxiety as to fire is afforded by hydrants fitted on every floor, with hose ready for use, and from every pavilion there are alternate egresses on each floor directly to the open air.

For *fresh air or sun baths* each pavilion is furnished with two sun balconies wide enough for beds, facing south, but otherwise sheltered from cold winds.

Out-patients' Department.—This contains a hall 120 feet by 41 feet, the floor of which is of patent stone, the walls of glazed brick and stone, and the ceiling is semi-elliptic in section. It has channels in the floor to enable squeegees to be used all over. It has windows on all four sides (all made to open), and a skylight at the apex of the ceiling. Fresh air is brought into the hall near the floor level behind the radiators, and in the turret is an electric aspirating fan.

Surgical Theatres.—The theatre units on the surgical side are in detached blocks to the north of the pavilions, where they are quiet and free from all distraction. Each unit consists of seven rooms, of which the anæsthetising room, the theatre, and the sterilising room are cut off by a cross corridor from the others. These have terrazzo floors, marble walls and opal glass ceilings; all can be washed down by a hose or wiped by hand, there being open floor sinks to take away all liquids. The doors, like those of the wards, are of smooth polished wainscot slabs without panels. The day lighting of the theatre is by windows and skylights on every floor, all having double panes of glass, and steel casements. The inlets of fresh air are protected by specially designed filter screens and the extract at the roof is by an electric fan.

The heating is by steam for purposes of rapidity, and so designed that temperatures from about 60° to 90° may be obtained to suit the operator. All lavatories, sinks and shelves are in the sterilising room attached, and are either of glazed ware, marble, or glass. The fittings, to avoid the dust of cleaning, are of nickel plate, and so are the supports of the glazed screen which partially separates the students' gallery from the theatre. This gallery is of marble and has a separate entrance. The electric lighting of the theatres

Digitized by Google

has received a great deal of attention from the surgical staff and varies in each to suit separate requirements. A low tension service for head lamps and instrumental work is laid on to all.

Reference should be made to the filtration of water for drinking, &c. Attached to every ward, to every theatre, and elsewhere, are twin simple filters, one for hot and one for cold water, connected by an arch with a bib outlet on which is a thermometer. Filtered or sterile water can thus be obtained at any required temperature for drinking, fomentations, poultices, &c.

Dietary.—In addition to the hospital kitchen each pavilion floor has a ward kitchen, with a gas kitchener and hot closet, specially designed, and so arranged that, without disconnection of the service, it can be wheeled out of the fireplace for keeping the recess clean.

The hospital kitchen, an apartment 60 feet by 35 feet by 29 feet high, and two large adjacent sculleries, of white glazed brickwork throughout, are fitted with a complete plant of every kind of apparatus for varied dietary, the caldrons tipping to pour out as simply as a cream jug. The gas fires on the tables are automatically turned on or shut off when saucepans are placed on or taken off, effecting an immense saving in the gas bill. Adjacent is a room for teaching cooking to the nursing staff. As part of the same block we have stores for all the varied goods required for nearly 1,000 people, and adjacent are the dining-rooms for all the varied sections of the staff and servants. (See *Architect*, Jan. 11, 1907.)

Safeguards against bacteria.—The obvious precaution against infection is the provision of a septic pavilion for the segregation of persons suspected of infection. This is to the south-east, there being a minimum zone of open ground of 40 feet, which has been shown to be effective, except in the case of smallpox. That disease will, however, probably be treated elsewhere. In this pavilion provision is made for the residence of the nursing staff and servants. At the out-patients' department there is an external ward to which an infected case can be at once transferred, and thence taken to the infectious hospital.

The doors of larders which face the windows are open panelled, and these panels and the windows are filled with copper gauze to exclude flies.

A steam disinfector capable of taking several mattresses at a time, is installed in the covered way at the entrance to the laundry, the infected side being absolutely shut off from the disinfected side. This is accessible through the open air from any building in the Infirmary. There are steam sterilisers in every theatre unit, for dressings, &c., and also for instruments.

Scalding sinks are fitted to every pavilion floor for cleansing vessels after use. A destructor for burning all infected food or other septic waste is installed near the boiler-house.

And lastly, the mortuary is a building containing thirteen double cubicles all refrigerated, so that decomposition or dissemination of noxious gases or germs are prevented.

Housing of the Staff.—In the home at the Infirmary (see *The Architect*, Jan. 4, 1907) every nurse has her separate bedroom, with a minimum of 1,000 cubic feet, ventilated and warmed. The exhaust ventilating flue from every bedroom is fitted with an adjustable valve. All upcast flues are collected into main trunks on the roof, ending in a vertical shaft in which is an electric fan; and the same principle is adopted in the servants' quarters. There are separate sitting rooms for sisters, nurses, and probationers, common recreation and reading rooms, a class room for lectures, besides separate quarters for assistant matrons and night superintendents. There are a large number of bathrooms and other conveniences, and all these are in towers or wings away from, but convenient for, all bedrooms. There are in this building five staircases affording alternative exits in the event of fire, and four of these staircases go to the flat roofs, whence extensive views are obtained. In the nurses' quad, open to the south, a tennis-court is provided, and there are ample stores for bicycles, &c.

The nurses' dining room, a large detached apartment with separate small tables, is so arranged that on special occasions it can be converted into a concert room. The servants are also located in ventilated and warmed bedrooms, and they also have separate sitting and dining rooms for every grade. The resident medical officers are quartered in the administration and teaching blocks, each with a sitting and a bedroom, in addition to common rooms. The offices consist of general and medical board rooms, each about 50 feet by 20 feet. The general superintendent's offices are in close proximity, and he has a comfortable residence in one wing of the building, the lady superintendent and the housekeeper being located in the other, with the general servants on the upper floor.

Teaching.—Another important sanatory adjunct is teaching, which is provided for in the north-west block in Oxford Road. (See *The Architect*, Jan. 18, 1907.) This contains separate common-rooms for male and female students, a large reading-room, a library, a museum, and a lecture theatre to seat 200. The theatre is ventilated by the admission of fresh air at many parts to change the whole atmosphere of the place at least three times an hour, with an extract fan in the double dome. Further provision is made for students in galleries in all theatres and in the consulting rooms of the outpatients' department.

Every member of the honorary staff on entering the Infirmary presses an electric button, when his presence is announced by means of indicators in every part of the hospital with which he is connected, including the out-patients' department. It hardly needs to be mentioned that every building is in telephonic communication with the others, and it should be added that electric clocks are installed everywhere, controlled and synchronised by a master clock, so that the same time exists throughout the Infirmary.

I now come to the last division of my subject.

The Æsthetic.—The superficial man may say, what has the æsthetic to do with the healing art? Is it not the science or art which deals with the beautiful, that which appeals to the senses? It is in this appeal to the senses, and I would fain hope to the imagination, that its curative value should be considered. I think the science of æstho-physiology deals with the organs of sense, of sensation and the influence of externals on the nervous system. The Greeks in surrounding themselves with objects of art had no doubt a keen sense of their value, not only in giving pleasure, but in their power to refine and cultivate the mind and raise it above sordid and morbid thoughts, above the trials and petty worries of life. The raison-d'être of our art galleries is based on these considerations. Their value to the people is undoubted.

In the Infirmary (see *The Architect*, July 5, 1907) the aim has been to make the external design impressive with dignity and stability, expressive of spaciousness and hospitality, appealing to the sick who enter to do so in hope, to feel that there is room and welcome for them in the place that generous hearts have raised for their especial care; and having entered to find in the ordered symmetry of the buildings with their air of repose, their sunlit rooms and pleasant quiet surroundings that which soothes their jarred nerves, stimulates their minds, and makes them responsive to the scientific skill that tends their bodily infirmity.

In the patients' wards themselves the colour scheme is simple—warmth suggested in the dado, while the pale green above is restful to the eye; the sense of freedom and expansiveness is given and felt in the ample and all round window lighting with the grass and trees beyond.

And last of all the buildings is the chapel (see *The Architect*, October 30, 1908). The æsthetic aim has been to mark a place apart where peace prevails; where harmonies in colour and in music may play their part; where the graces of faith, hope, and charity divine, so brilliantly depicted, may make their own appeal; where all may reverently join in prayer and praise and learn the allegory of the sanctuary rail: that from the hardest cross with patience borne shall spring the fairest flowers of character, and the weary soul shall be refreshed by communion with the source of strength.

LONDON COUNTY COUNCIL ARCHITECTURAL PRIZES.

A NOTICE was inserted in the *London County Council Gazette*, and information was sent to the polytechnics and technical institutes, with reference to the award of prizes for museum and architectural studies. One prize of 10*l.* and two prizes of 5*l.* each are offered for sets of carefully executed drawings of buildings, churches and of artistic objects in museums. The drawings for which prizes are awarded become the absolute property of the Council, and the work must have been executed since Easter, 1908, and not previously submitted in another competition. The examiners report as follows:—"The drawings submitted this year are admirable. Fifteen students in all competed and the quality of their work is higher than ever before. We recommend for the first place (prize 10*l.*) Helen Consey, for the second (5*l.*) John E. Tarbox, and for the third (5*l.*)

Digitized by Google

Eva Dunn. We wish also to commend highly the drawings of William H. Broad, and to recommend that they be purchased for 5*l*. Excellent drawings were also submitted by Dora Bard, Elfrida Dadd and Mary Gilbertson, but they sent only one drawing each." With regard to the purchase of the drawings of William H. Broad, the education committee do not consider it advisable to carry out the examiners' recommendation, as the purchase of the drawings is, in effect, the same as the award of an additional prize of 5*l*., and in view of the importance of maintaining a high standard they think it undesirable to increase the number of prizes.

The Council on April 15, 1908, had before it a report dealing with the competition for the prizes in that year, and resolved that in the educational year 1908-9 one prize of 10*l*. and two prizes of 5*l*. each be offered for museum and architectural studies, and that the question of the continuance of the award of the prizes be considered in 1909. In view of the favourable terms of the examiners' report, the education committee recommend that, until further order, the award of prizes for architectural and museum studies be continued, and that one prize of 10*l*. and two prizes of 5*l*. each in respect thereof be offered annually.

Steelwork.

SIR,—I have just read the article by Mr. Childs in *The Architect* of January 15, and with your permission I propose to comment upon the statements therein put forward.

At the outset I think your readers should be made acquainted with the fact that Mr. Childs is professionally interested in a fireproofing company, one of whose specialties is an ingenious variety of reinforced concrete floor. Consequently his opinions and arguments cannot be accepted in quite the same manner as those of an independent engineer.

On reading the article for the first time I wondered why the representative of a reinforced concrete firm should think it worth while to try to disparage the value of that material, apparently to the detriment of the business conducted by his company. But after a second reading it became obvious that the article was only directed against the use of reinforced concrete for purposes other than the construction of indoor floors. Arguments of the kind are perhaps legitimate in commercial prospectuses, but I scarcely think they are appropriate to the columns of a professional journal, especially when the interested status of the author is not announced.

The figures upon which Mr. Childs relies for support of his pleading are approximately correct up to a certain point, although they tend slightly against reinforced concrete, and, as I will show, they are not correctly applied. Thus, while the extensibility of plain concrete is one 10,000th or 0.0001 of its length, the elongation of steel for the tensile stress of 7 tons and the usual value of the coefficient of elasticity of 30,000,000 lb. per square inch is one 1,900th or 0.000523 of its length, instead of one 1,700th of its length, as stated.

Then in a beam where the maximum tensile stress of 7 tons per square inch is developed in the steel at the middle of the span, the steel will elongate at the same point 0.000523 of its length, and the concrete, after elongating 0.0001 of its length, must further elongate or open out in some way to the proportionate length of 0.000523−0.0001 =0.000423.

Mr. Childs probably knows, but omits to say, that the maximum tensile stress due to bending moment obtains only at the middle of the beam and progressively diminishes towards the ends, where the value is zero. It is important that this variation of stress distribution should not be overlooked, because the strain in the concrete diminishes from the middle of the span in like proportion, and also because it shows that the maximum stress cannot extend along "a two-foot length of the beam," as Mr. Childs implies. The variation of stress intensity in a two-foot length might be small, and for the purpose of a supposititious computation it may be neglected. But it is manifestly incorrect to suggest that the uniform elongation of a steel bar could exert force so unequally as to cause only one crack to open in a two-foot length of the embedding concrete.

The investigations of Considère in 1902, those of Mesnager in 1903 and the second series by Considère in 1904 showed that reinforced concrete was capable of elongating without cracking from ten to twenty times the extent possible in the case of plain concrete. This conclusion was accepted by authorities such as Emperger, Hatt and Sanders, but Talbot and Turneaure in America afterwards succeeded in detecting very minute and numerous cracks in reinforced concrete beams, where the concrete had apparently elongated in the manner observed by Considère and the other authorities mentioned.

While the correctness of Considère's results has never been disproved, it is tolerably certain that very small cracks appear on the surface of practical beams after the concrete has elongated beyond the proportion of 0.0001 of its length. These cracks, however, are invisible without the aid of a microscope, and, as Talbot and Turneaure state, are numerous and quite well distributed.

Consequently, instead of one fissure in a two-foot length of a beam, there are probably hundreds of invisible hair-cracks, by which, as Professor Turneaure says, "the steel develops the full extensibility of a non-homogeneous material that otherwise would have an extension corresponding to the weakest section."

If there really were but one crack in a two-foot length its width at the level of the steel would be (0.000423×24) =0.00105 inch, or one 100th inch, instead of one 70th inch, as given by Mr. Childs, and even assuming ten hair-cracks per inch length of the beam, the width of each would be no more than (.000423 ÷ 10) = 0.0000423 inch, or one 23,600th inch. Thus the single large crack imagined by Mr. Childs for the purpose of trying to demonstrate the dangers of reinforced concrete, when not applied in the particular manner favoured by his own firm, is 330 times wider than the probable width of fine hair-cracks such as those discovered by Talbot and Turneaure.

Of course, the hair-marks would develop into wider, longer and deeper cracks if excessive strain were put on the reinforcement, and if the concrete were of poor quality or badly prepared it might fracture at one point in a beam. Diagonal cracks may also appear in beams which are not properly reinforced against tension on diagonal planes. I hope no unhappy contretemps has led Mr. Childs to suggest the creation of a single crack as a normal feature in a two-foot length of a beam; my own experience of numerous well-designed and carefully constructed reinforced concrete beams being that no cracks of any kind are observable under test loads involving stresses up to more than 10 tons per square inch in the steel.

Having now made clear the actual extent of any hair-cracking tendency that may develop in properly constructed reinforced concrete beams, I should like to add a few words relative to the probability, or rather the improbability, of corrosion on the surface of the steel bars.

The rusting of steel does not occur except in the simultaneous presence of water, oxygen and an acid. If any of these agents be absent very little corrosion takes place, and what is more important still, the presence of an alkaline compound will prevent the process of rusting.

Although air would naturally gain access even to the interior of a crack so small as one 23,600th inch wide, and moisture might work its way in against the pressure of the confined air by capillary attraction, there could be very little chance of the moisture penetrating to the top of so minute an aperture, and the presence of acid would be a still more remote contingency. If all three agents were present there might be the risk of corrosion over an area measuring, say, ¼ inch by one 23,600th inch on each bar of the reinforcement. Your readers can decide for themselves whether the possibility is one justifying the alarming prophecies of Mr. Childs.

But there are further reasons for dismissing his gloomy forebodings. They are to be found in the facts (1) that the Portland cement around the steel is an alkaline compound abundantly capable of neutralising any infinitesimal quantity of acid that could find its way into an invisible crack; and (2) that the water mixed with the concrete combines with the surface film of rust always present on the bars before use, forming an insoluble, impenetrable and permanent compound, which effectively protects the metal from corrosive agencies.

Beams used out of doors in the ordinary way are practically as well protected from moisture as beams in a building. The under side is generally shielded from water, and the proportion of moisture and acid gases contained in the air is much smaller than that in any building occupied by human beings and animals and in many buildings used for industrial purposes. If Mr. Childs's arguments were valid

Digitized by Google

it might even be said that the steel in reinforced concrete beams employed indoors is in greater risk than the steel in similar members situated in the open air. Mr. Childs is playing with what he probably imagines to be edged tools in a way that would be dangerous to his own interests if the tools had any edge in reality. Of course, in the case of compression members, which are very largely used in reinforced concrete construction, no question of the kind discussed by Mr. Childs can possibly arise.

In conclusion, I wish particularly to express my conviction that what Mr. Childs has written has been put forward in perfect good faith, but I am afraid that he has been influenced, quite unconsciously, by environmental influences. On the other hand, he may possibly consider me to be one of those referred to in his article as "enthusiasts" possessed by the "craze" for reinforced concrete construction. That point and the subject generally, however, are matters which I am content to leave to the judgment of your readers.—Yours faithfully, W. NOBLE TWELVETREES.

London, S.W.: February 13, 1909.

Consett Schools Competition.

SIR,—I have no doubt you have been interested in the above competition. Conditions were sent out to architects for competitive plans, the award made, and now "circulars" have been sent out to the "unlucky" architects asking if they object to the plans being returned "minus the strainers." I think it hardly fair, after all the trouble taken in the preparation of the plans, having them returned in this fashion just to save expense. Some architects go to a great expense in competitions, and if this is how their plans are to be returned, it is time competitions were "off." COMPETITOR.

St. Paul's.

SIR,—As the central object in London, everyone's attention is called to the cathedral, and a few remarks upon it may not be uninteresting to your readers. It often struck me how picturesque and scenic it was, and I used to wonder that it was not more used as a subject by artists. For instance, I cannot call to mind a picture of it by Turner, or any of the great artists, and yet everyone must be struck with the beauty and picturesqueness of the views of it from every side. It is so wonderfully broken up and divided into separate views and pictures. This is not at all a characteristic of Greek, Roman, or Renaissance architecture, but is distinctly the character of Gothic. The great western façade is divided into two storeys by two rows of columns, and curiously there was no necessity for this, as it is neither a two-storeyed building nor are there any side aisles necessitating this, as in a Gothic church. I remember noticing this when I saw the great pillars of St. Peter's at Rome stretching right up to the top of the main building, and in temples like the Parthenon at Athens the Doric columns rise from the floor, and carry in one piece the entablature and the pediment. In fact, the great columns in Westminster Abbey and the French cathedrals are more Classic in feeling than Wren's internal and external columns. It is curious to note how Wren's pupil Gibbs, in the church of St. Mary-le-Strand, follows his master in designing a two-storey Renaissance building, but afterwards in St. Martin's-in-the-Fields gives us a purely Classical one-storey temple. John James, in Marylebone and St. George's, Hanover Square, gave us good examples of how noble and grand a single row Greek temple façade of columns, in height reaching to and carrying the entablature, can be made. As Goethe says:—"So largely designed and carried out, I do not know how it came about that Wren, a Renaissance architect, came to build in the Gothic spirit." Whether it was his own fancy or imposed upon him, some of your readers may be able to tell us. I am glad to have had the opportunity of calling their attention to the fact.

H. W. FAWCUS.

Walden House, Marylebone, N.W.

Mr. R. S. Lorimer, R.S.A., Edinburgh, has been appointed to advise the green committee of St. Andrews' Links as to the Tom Morris Memorial, for which 600*l.* has already been subscribed.

Mr. H. F. Kerr, A.R.I.B.A., 62 Hanover Street, Edinburgh, has been appointed architect for the David Murray Homes. The trustees are now looking for a suitable site of about two acres in extent, in the neighbourhood of Edinburgh.

GENERAL.

Mr. G. T. Hine, architect, Westminster, S.W., has been engaged by the Hampshire County Council as architect for the erection of an asylum at Park Prewett. In 1902, when it was decided to postpone the building of an asylum, Mr. Hine was paid 465*l.* 15*s.* for his services in connection with the work of planning the asylum, and it was agreed that that payment should merge in his ordinary 5 per cent. commission on the completion of the work.

The Establishment Committee of the London County Council recommend that 890*l.* be paid to Mr. W. E. Riley, the Council's official architect, in part payment of his services in connection with the new County Hall. The Council state that, apart from the large amount of work Mr. Riley has done in connection with the plans of the new County Hall, heavy and responsible duties devolved upon him as one of the assessors in both parts of the competition, and although his fellow assessors were each paid the sum of 1,050*l.*, Mr. Riley has not received any remuneration for this special work. The commission on the work is to be paid in the proportion of nine-tenths to Mr. Ralph Knott and one-tenth to Mr. W. E. Riley.

A Further Portion of the stained-glass collections formed early in the nineteenth century by George Weare Braikenridge, of Broomwell House, Brislington, near Bristol, will come up for sale at Messrs. Christie's on Friday next, and will comprise the extensive collection of stained-glass panels of the fifteenth and two succeeding centuries. There are seventy-six lots, Dutch stained glass forming two-thirds of the whole collection.

The Carnegie Dunfermline Trust are carrying out a scheme of operations, with the sanction of the Crown authorities, with the view of laying bare more of the ruins of the monastery connected with the Dunfermline Palace. Large quantities of forced soil are being removed from the base of the walls with the object of revealing the base courses. Along with that work the trustees are preparing for a scheme of street widening on both sides of Monastery Street, which will not only render the conduct of traffic safer in view of the narrow neck at the Pend, but will throw the massive walls of the Palace and monastery into more prominent relief.

Mr. Norman, the chairman of the establishment committee of the London County Council, stated in reply to a question on Tuesday that the amended plans of the elevation of the new County Hall were now before the professional assessors, and when they came back from them they would be submitted to the Council. He saw no objection to the amended plans being shown so that the public might view them, as was the case with the original plans.

While Preparing the municipal cricket pitches on the South Common, Lincoln, workmen have unearthed broken portions of a memorial tablet of the Roman period. It was found that, with the exception of two letters, the inscription was intact. The relic has been removed to the Lincoln City and County Museum, and the inscription has been translated as follows:—"Gaius Valerius Maccenas, the son of Gaius, soldier and standard bearer of the Ninth Legion called Hespes; he served thirty-five years and saw thirteen campaigns. He gave orders in his will for the erection of this monument. He is buried here."

The First of the Series of Lectures on the "History of Art in Europe," by Mr. Windsor Fry, was delivered at the School of Art, Crystal Palace, on Monday evening last with limelight illustrations. A chart illustrating the whole period from the fourteenth to the nineteenth century in the different countries was displayed, and a very interesting discourse was given on the Giotto frescoes and the artists of the Florentine school, who were often architects and sculptors as well as painters. The Sienese school of painting was also touched upon.

At the Meeting of the London County Council last week a member asked whether any precautions against fire were taken at the Royal Albert Hall; whether the building was inspected by the Council's officials; and, if not, whether it was not the only building which was not so inspected. The chairman of the theatres committee replied that the hall had not been inspected by the Council, and the Council had not been asked to make an inspection of the building. The facts with regard to the hall were reported to the Council on July 10, 1906. According to the terms of the Charter, the hall was exempt from the necessity of being licensed for music and also from the requirements of the London Building Acts. In view of its large size, it would, in his opinion, be well for the safety of the public if it were brought into the same category as other places of amusement.

The Architect.

THE WEEK.

A MOTION on behalf of the Westminster Hospital, to restrain an interference with the lights of that institution by the new Wesleyan Memorial Hall, having come before Mr. Justice JOYCE in the Chancery Division on Friday last, his Lordship intimated to the counsel engaged in the case that, as charitable money was concerned on both sides, he proposed to appoint a competent and efficient expert to see the plans and report to him, thus saving the great expense to both charitable funds of *ex parte* affidavits. Counsel for the hospital said he would be glad if his Lordship would like to instruct a report to be made at once, but as the counsel for the Trustees of the Wesleyan Methodist Twentieth Century Fund wished to consult his clients on the matter, the motion was adjourned for a week, all proceedings with regard to affidavits being stayed meanwhile.

THE Earl of ROSEBERY, having been elected President of the London Topographical Society at its tenth annual meeting, last Friday, took for the subject of his presidential address the old Palace of Whitehall, the history of which he characterised as elusive, one reason for this being that the prints connected with it were rather those of what might have been than what was—illustrations of INIGO JONES'S designs for a palace that never existed. Another reason was that, though the Royal apartments were burned down in the fire of 1698, which was supposed to have put an end to the structure, the great mass of the Palace seems to have escaped. All that can now be described with any certainty as existing parts of the old Palace, besides the banqueting house, are a couple of cellars and as many windows, these latter being in the present passage leading from Whitehall to the Treasury. In one of the cellars the cocks were kept for the battles of the neighbouring cock-pit, which was on the site of the present Treasury. The other was a wine cellar underneath the spacious courtyard at the Charing Cross entrance to the Palace, where Carrington House used to stand. Another entrance to the Palace was the Holbein Gate, where Dover House now stands. This gate, designed by HOLBEIN for HENRY VIII., was carried away by the "Butcher" Duke of CUMBERLAND, to be placed at the end of the Long Walk at Windsor, since which nothing has been heard of it. The Palace precincts comprehended what is now called the Horse Guards, known then as the Tilt Yard, and also Scotland Yard. Stretching away to the left of the Holbein Gate, and on a line with it, were the Government Offices, and on the right a multifarious collection of Palace lodgings, extending nearly to Westminster, where there was another entrance, the King's Gate. The Palace was composed of a mass of unimposing buildings, a maze of dwellings and offices, with the magnificent banqueting house of INIGO JONES in the centre. Lord ROSEBERY concluded his address by emphasising the fleeting character of London, where nothing remained permanent, for our leases ran out just as our judiciously constructed houses were going to pieces. He exhorted the Society to garner up carefully what was worth preserving of a great city, built not for time or posterity, but for the business exigencies of a leasehold tenure.

THE future of the India Museum at South Kensington is a very pretty question, and one as to which there is hardly a possibility of agreement between the opposing parties, whose feelings are entirely dominated by their separate points of view. The official proposal to break up the unity of the present collection and to redistribute it among the various sections of the Victoria and Albert Museum, according to "material," commends itself to those who view the great art museum of the country as a means of study to specialised craftsmen, so that, for example, the designer for textiles may be able to readily compare the work of an Indian artist with that, say, of a Hungarian worker in the same material, recognising that design is not a thing apart, but is subservient to and regulated by the material to which it is applied. This view appeals therefore to those who consider the Victoria and Albert Museum as a place for the study of design, and to them the official proposal appears the right course to pursue. It is not surprising to those who know him that Sir CASPAR PURDON CLARKE, though no longer associated with our museum, upholds the official proposal. On the other side are ranged those who value the entity of the collection, either politically or archæologically, because it is Indian, and consider that its redistribution "would annihilate a most valuable means of learning to understand Indian art, and, what is more important, something of India itself." This is a perfectly comprehensible view, and one can readily understand that it is held by such men as Lord CROMER, Lord CURZON, and Lord ROBERTS; nor is it surprising that Mr. ERNEST GEORGE, the President of the Royal Institute of British Architects, Professor SIMPSON, and Mr. R. PHENE SPIERS are signatories of the memorials in favour of the preservation of the Indian collection, for architecture embraces all arts, and views Indian art as a whole. We think, however, that the memorialists go too far when they say "that the distribution of the Indian collection as proposed would not further a sound principle of education." The grouping together of the art products of various countries according to "material" as a means of studying design in any particular material is a perfectly "sound principle of education," though not perhaps so favourable to that precise phase of education to which the memorialists incline. The adoption of the views of the memorialists with regard to the Indian collection would logically seem to entail a similar treatment of the remaining exhibits in the Museum, and the art of France, of Germany, of Italy, and every other country should be similarly grouped. The Museum would then be rather for the dilettante and the casual visitor than for the serious student, and would thus miss what, after all, must be allowed to be its principal sphere of usefulness. The obvious solution, if it be possible, is the adoption of the ideal arrangement of an exhibition into which an international character enters, the arrangement in concentric and radial sections—concentric according to material and radial according to nationality, or vice versâ, as may be more convenient.

THE Americans have had so much more experience than ourselves up to the present with reinforced concrete construction, that due weight must be given to the opinions of one so well situated to form a deliberate and cool judgment as Mr. JAMES KNOX TAYLOR, Supervising Architect of the Treasury Department of the United States Government. He is reported by the *Washington Herald* to have said:—"I would favour the further use of reinforced concrete in the construction of Government buildings if it were possible for us to get a sufficient number of expert superintendents to take charge of the work. It requires careful and expert watching. I am afraid that we shall always encounter—or for a long time, at least—the same difficulty that we find now in its use, namely, that while we can easily get superintendents, we cannot get a large enough number of them who are highly trained in the use of concrete. There is too much danger in the indiscriminate use of concrete to permit us to try to make it a common material in the construction of Government buildings, unless, or until, this danger can be in some way eliminated." This is indeed the crux of the whole question in respect of reinforced concrete; absolutely capable supervision to ensure absolutely correct workmanship is a primary essential for reliability and for safety. Both the mixing of the concrete and the placing of it in position must be carried out with perfect fidelity to the prescribed and theoretical arrangement, or failure will result.

THE ACROPOLIS OF ATHENS.*—II.

OUR author does not confine himself to the purely archæological questions relating to the architectural and sculptural remains of the Athenian Acropolis, but directs his readers' attention to some of the minutiæ that help to make its buildings pre-eminent in artistic merit. The first of these to which Professor D'OOGE alludes is the curvature of quasi-straight lines in the building of the Parthenon, and he rightly pays tribute to the painstaking and exceedingly careful investigations of the late Mr. PENROSE on this subject, the refutation of whose objectors is very ably and clearly stated. The Professor points out that the rule of curvature applies universally in the Parthenon, so that in the entire building there is not a single straight line of any great length; also that there is no vertical surface exactly plumb. The entasis of columns and the inclination of their axes are some of the results of fidelity to these principles. The effect of these refinements is well expressed by Professor D'OOGE when he says that they "produce in their totality an impression of elasticity and rhythm which every beholder feels as he looks with admiration upon this structure so full of life and grace." The difference in the point of view of the professional and the lay admirer of artistic work has seldom been more happily formulated. The lay beholder feels, the artist knows the effect of consummate artistic craft.

Professor D'OOGE has, however, missed two of the most important elements in the perfection of the Parthenon, and this although he instances so very small a point as the uniform depth of the flutings of the columns, which he tells us was maintained in order to produce as much shadow as possible at the top. The consequent effect of strength is undoubted. It is also to be found in the difference of character between Early English and Decorated mouldings, but practically it was also easier for the masons thus to maintain true alignment of the flutes as they were cut *in situ* from starting-points at top and bottom of the columns.

The elements that Professor D'OOGE has missed are, first, proportion, and, second, the contour of mouldings, both of which are more vitally important in producing the impression that every beholder feels than are the refinements to which the author refers. The systems of proportion that obtain amongst the best works of Greek architects have been excellently explained by Mr. PENROSE, and have probably more to do with the effect produced upon the beholder than any other element of the architectural design. Mr. PENROSE has also shown that, save—as we remarked in our former article—for the cymatium, every moulding in the Parthenon is a curve of conic section or a combination of such curves, and his extreme conscientiousness may be accepted as a warranty of the correctness of the facts that he discovered. This does not necessarily imply that ICTINUS and other Greek architects consciously observed the principles of proportion discovered by Mr. PENROSE, any more than that the principles of composition that RUSKIN pointed out as dominating the pictures of TURNER were consciously followed by the painter. A great artist may sub-consciously and instinctively embody in his work fidelity to great truths that are but faintly adumbrated in his active and conscious mentality.

The view has been advanced that the Greek architects drew the sections of their mouldings freehand, because it was not till after the completion of the Parthenon that mathematicians studied and described the parabola, the hyperbola, and the ellipse as sections of the cone. It is, however, comprehensible that curves of conic section were used by architects, because they are lines of constantly and regularly varying curvature, and hence give mouldings of exquisitely gradated chiaroscuro. They are besides perfectly easy to set out from the directrix and focus, and we venture to think that mathematicians would have been a long time discovering the importance of these determinants had they not been in practical use by architects. Our view that the Greek architects deliberately drew for the contours of their mouldings curves of conic section, without knowing that they were such, is strengthened by the fact that the parabola was earlier used than the hyperbola, and that in not a few instances of Doric capitals the vertical line through the plane of the abacus is the directrix of the curve of the echinus.

A most important factor in the work of Greek architects and sculptors that it is difficult for us nowadays to comprehend is their polychromatic treatment, and Professor D'OOGE appears to have adopted what we regard as the entirely correct view, that every particle of stonework, whether of Pentelic marble or less exquisite material, was coloured. There can be little doubt that the Greeks did not value marble as we moderns esteem it, for its surface texture, for if they had done so they would scarcely have covered it with stucco, as we know to have been their practice upon occasion. Crude and harsh as the primary colours used by the Greeks appear to our northern eyes, deadened to appreciation of polychromy by the practice of the eighteenth and nineteenth centuries, we must remember that in the powerful light of southern lands such brilliant colouring has a harmony that appeals even to us. In more northern latitudes bright colours, harmoniously used, are still pleasing to our untrained and atrophied senses. When FREIHERR VON HANSEN built the Parliament House at Vienna in pure Greek Doric style, he coloured a portion of one of his façades exactly on the lines of the Parthenon's polychromy, and the effect was decidedly satisfactory.

It is universally admitted that mouldings and projecting architectural members were coloured by the Greeks, as were also the backgrounds of sculpture in pediments and friezes. DÖRPFELD and some others hold that it was the custom of the ancient Greeks to leave plain surfaces of marble buildings untinted, but such a view is artistically unthinkable, and is, in our opinion, completely demolished by the recent experiments of some American investigators described by Professor D'OOGE, and particularly of Professor ALFRED EMERSON, who has arrived at the conclusion that the Parthenon and marble buildings generally, sculptures and all, were covered with a wash of calcareous matter—in other words, distempered—and that this artificial tinting is meant when VITRUVIUS says that the ochre quarries of Attica were exhausted by the old-time practice of painting the buildings with ochre. The patina of old Pentelic marble is far more likely to be due to such distempering with ochreous limewash than to the action of the atmosphere on any iron that may have been present in the marble. It is now beyond dispute that portions of the sculptures were coloured, and that accessory parts were of metal, in the form of weapons, wreaths, reins and bridles, sashes, sword-belts, &c., and it is therefore impossible to believe that in the best period of Greek art the whole of the sculpture was not coloured; the more so as we know for a certainty that this was the ordinary practice in earlier work.

The non-completion of the original designs of some of the great buildings of the Athenian Acropolis is well elucidated by Professor D'OOGE. Grand as it is, the Propylæa, "the brilliant jewel on the front of the rocky coronet of the Athenian Acropolis," is but a fragment of the original conception of MNESICLES, and the plan of the complete scheme, as very cleverly argued by Dr. DÖRPFELD, though necessarily largely a matter of conjecture and in some points open to objection, may at least be reasonably accepted as a legitimate speculation. Space does not permit us to fully discuss the line of argument followed by Dr. DÖRPFELD, and we must refer our readers to the very clear exposition by our author of the facts and the theories founded on those facts.

We are glad to find that Professor D'OOGE has placed before English readers the view now adopted by Dr. DÖRPFELD of the complete design of the Erechtheion. It is utter banality to describe this beautiful building in its incomplete realisation of its author's original design as an

* *The Acropolis of Athens.* By Martin L. d'Ooge, Professor of the Greek Language and Literature in the University of Michigan. (London: Macmillan & Co. 1908. 17*s.* net.)

Digitized by Google

example by Greek architects of unsymmetrical planning. Students at the Architectural Association have years ago heard the argument:—"No architect who was not a fool would design a portico extending beyond the end of his building. The Greek architects were not fools. Therefore the Erechtheion must have been intended to project westward beyond the north portico and probably as far as the eastern end." This is the view now adopted by DÖRPFELD, who, in his plan, illustrated by Professor D'OOGE, makes the north portico the central feature of a symmetrical plan. To an architect it is preposterous to suppose that any other intention ever entered the mind of the great Greek artists. Everything confirms the probability of such an intention, and even the slight eccentricity of the caryatide portico, explainable as we have already pointed out, is no argument against this view.

We must not close without expressing our high appreciation of the account given by Professor D'OOGE of the sculptured remains of various dates, of the temples and shrines on the southern slope of the Acropolis, and of its history in the Hellenistic and Roman periods. We may characterise the book as a most able and interesting epitome of all that is known or conjectured about the Acropolis of Athens.

ARCHITECTURE: ITS TRUE PRINCIPLES.—IV.

By R. OWEN ALLSOP.

THE NATURE OF ORIGINALITY IN ARCHITECTURAL DESIGN.

THE knowledge of detail acquired by the student of architecture should not be regarded as samples to be "worked in" to a composition. The acquired knowledge of form and arrangement must go through a milling process in the mind, and there must be besides corn gathering a sifting of the chaff. There must be a bottomless pit. So long as any one piece of design is a stencil copy of some precedent, the hand and brain of the designer will be more or less completely paralysed. If this is a true statement—and we see no reason to suspect any flaw in the premises—it once for all explodes the "Order" theory. The matter can be tested for oneself. Let a design be laid down, and as a commencement a most exact copy of a Grecian order, base, column, capital and entablature be set as a key note. If the architect is an artist—*i.e.* has a sense of æsthetics—the whole of the parts added to such a design will be cramped and bound by the key note thus struck His brain will be in leading strings. Contrary to the great necessity for original action, the sense of fettering will be complete. True design is an inspiration, an initiative born of we know not what. The mind must be absolutely free and untrammelled, or the muse will be invoked in vain. Recently in the competition for the new London County Council premises a sketch plan was put before the architects as a suggestion. No greater mistake could have been made by the promoters of the competition. It is encouraging to find that this was quickly appreciated by the intending competitors. The objection to the arrangement was well put in the round-robin signed by several competitors, "This arrangement tends to destroy the real architect's enthusiasm and initiative (and) damages his self-respect." Self-reliance would possibly have been a better term, but the intention and sense is clearly correct. If we are seeking the best of another brain's assistance this latter must be left free and uncontrolled. To attempt to dominate another mind results—if the attempt is successful—in a weakening of the powers of the subordinate brain in measure to somewhere between the extremes of rebellious concession and slavish service. It is the death blow to all imagination. Practically the effect is to get less value in work from the servant.

If then, it may be argued, the mind of the designer must be free and untrammelled, and least of all a copier of old forms, we should avoid—should be better without—the study of bygone architecture. This we know is a wrong assumption. Sir JOSHUA REYNOLDS observes:—"The greatest natural genius cannot subsist on its own stock. He who resolves never to ransack any mind but his own will be soon reduced from mere barrenness to the poorest of all imitation; he will be obliged to imitate himself, and to repeat what he has before repeated."

The system of sketching affords practice in pencil control, and enforces close observation of the thing sketched and interesting mementos and records; but it may be stated as a general rule that no architect should require to refer to note-books save but for "motive." An author does not refer to his predecessor to copy his sentences, except as a direct quoted reference. The memory must be the storehouse, and reason the threshing and winnowing machinery that separates the good and useful from the dross. Unknowingly the designer may reproduce line for line the conception of another, but so long as he was unaware of the fact he cannot be stigmatised as a copyist. In the case of limited study and experience the production of the designer would certainly be at best a very strong echo of some of his special studies; hence it comes about that the more study of the work of others the more original one's own work becomes. If we have read only one author's book on any given subject, and then endeavoured to essay on this subject, we may rest assured that strive as we may the spirit of whole sentences of that author will permeate our production.

FIG. 12.—KARNAK.

On the other hand, if we have read largely all we can lay hands on bearing on the subject, the several ideas of the writers may be passed through the fire of thought, and with the exercise of reason and comparison—a large component part of the faculty of reasoning—we are enabled to give original views based possibly to some extent on a selective process, whereby we cast out what reason refuses to accept and put down what reason acclaims as true and sound. These opinions will be partly a recombination of old ideas and novel ideas suggested by old, and "originality" arising from inductive reasoning. The essential part of the process is that there should be evidence of brainwork.

If design is the impress of the right use of the functions of a healthy brain the mind must be the master of the whole work. There must be no superstition—no "standing under" any other brain. The action of the mind upon the matter of an architectural composition may be compared to that of the bee in producing honey. The material—the various flowers—differ, but one and all contribute to the honey which is one substance, just as there is homogeneity of character in the product of the brain—that is, what comes out of it after the act of right reasoning. There can be no two ways in dealing with the question of Orders of architecture. The Order must go as such, unless indeed reason and the eye together working repro-

Digitized by Google

duce exactly the Doric, Ionic or Corinthian forms, proportions and details. Directly the brain ceases to work, as it does in a sense immediately we commence to transfer dimensions from old examples to new work, the artist dies and the machine-like copyist reigns in his stead. No logic can put the matter in any other light. It has been advanced that if we would reproduce an "Order" it should be correctly drawn. This may be so, but the question arises—of what value is the thing when reproduced?

Originality in architectural design, then, may be defined as the product of reason and knowledge. It assumes principle, and is the ultimate outcome of refinement and delicacy of the eye, the hand, and, indeed, also the heart. We have seen that originality should be sought in novel combination of old forms We do not sigh for some

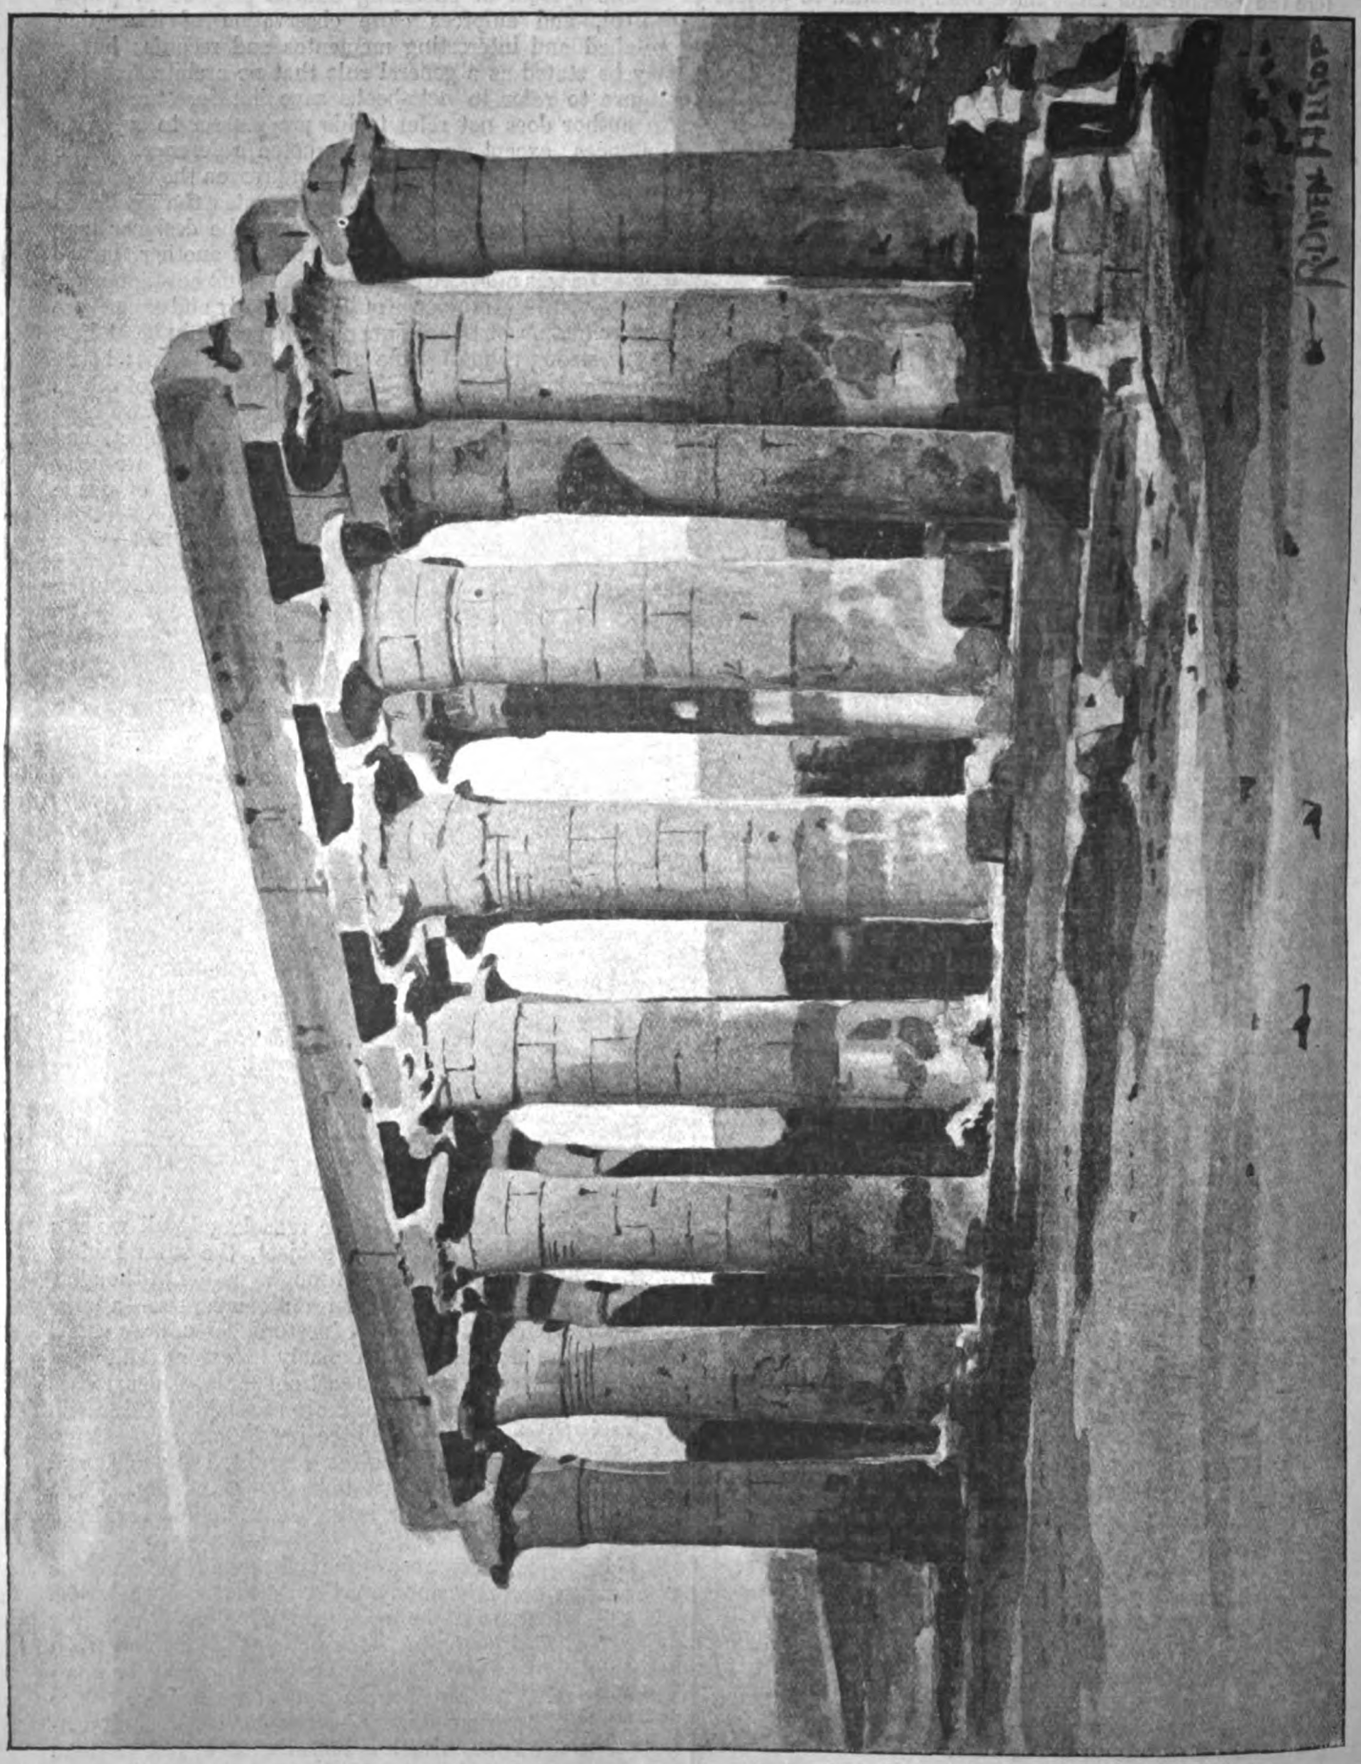

FIG. 13.—LUXOR

Digitized by Google

substitute for the sphere, the square, the equilateral triangle or the circle. We can infinitely vary the surface its proportions, the line its length, and the angle in its degree.

The kind of Order that should more concern the architect is that which has been termed "Heaven's first law." Ungainly building masses are, fundamentally, the expression of disorder. A row of equal-spaced columns seems to please primarily by the sense of order conveyed. All arise from the same base line, have axes on one plane, and are truly "plumb." Majesty of effect seems to be in direct ratio to geometrical simplicity of main mass; hence a group of columns, such as Luxor, cannot but powerfully impress us although the amount of actual design may be small. Conversely, a scene such as that at Karnak depresses by its impression of disorder, relieved only by the perpendicularity of the standing obelisk and the relentless geometry of that which has fallen.

(To be continued.)

THE CONCRETE INSTITUTE.

THE third general meeting of the Concrete Institute was held on Thursday, the 18th inst., at the Royal United Service Institution, Whitehall. Mr. Edwin O. Sachs, F.R.S., Ed., the chairman, in opening the proceedings said it had been the custom at previous meetings to make an announcement as to the increase in membership of the Institute. At the first meeting there were 300, at the second there were 401, and in the intervening period the numbers had increased to 551. Mr. Lucien Serraillier then read a paper dealing with "The Commercial Aspect of Reinforced Concrete." The lecturer began by stating that the relation which subsisted between (*a*) the client or principal, (*b*) his technical adviser, and (*c*) the contractor in ordinary civil engineering and architectural construction was more complex in reinforced concrete construction, while the recent advent in England of firms which were endeavouring to popularise this particular industry has further intensified the complexity of this relation. The present paper was an attempt to define the duties and responsibilities towards each other of the various parties engaged in this class of construction, to explain the conditions which govern its exploitation, and to determine between (*a*) the principal or engineer and architect, (*b*) the specialist firm which confines itself to this branch of construction, and (*c*) the contractor, an equitable relation which should as far as possible conciliate all interests and eliminate those injustices which now unfortunately arose, undoubtedly through ignorance of those peculiar conditions rather than through intention.

The principal, or his technical agent the engineer or architect, hereafter called the client, had two methods at his disposal under which reinforced concrete work could be undertaken:—(1) He might design the structure himself, and either confide the work to a contractor under his supervision or else carry it out himself with his own gang of men; (2) he might entrust the design to a specialist firm, and either carry it out himself with his own men, or with his own contractors, or else get the specialist firms to do it themselves or through contractors selected by them.

The first method was the usual practice adopted in general civil engineering and architectural construction, whereas the second method might be said to be peculiar to reinforced concrete, although sometimes adopted for steelwork. The technical and practical difficulties of the reinforced concrete industry were of such a special nature that the client generally preferred to employ a specialist firm, to whom he thus delegated his duties and responsibilities, contenting himself with a secondary control.

Division of the work.—Reinforced concrete work might be subdivided into (1) the design; (2) the execution; (3) the reinforcing material employed (as also other materials of construction which do not concern us in this paper). These were respectively contributed by the designer, the contractor, and the merchant. By designer the lecturer understood the engineer, the architect, or the specialist firm, as the case might be, who was the author of the design. The contractor was the one who executed the work, and was not necessarily distinct from the designer, whilst the merchant might be, and was in some cases, both designer and contractor. The work was carried out from start to finish through the separate agency of these three divisions, or by combinations of them, and it was precisely those combinations which introduced the complications to which he referred at the commencement of the paper. In ordinary construction, matters were simple enough, because the engineer or architect who was the designer of the work assumed control of its execution, and was responsible for such, although any mistake on his part affected his reputation, but never his pocket. In that case the designer not only controlled the contractor, but indirectly, through the latter, also controlled the merchants who supplied the material; he had the right of rejection, and in virtue of the fact that he held the purse-strings his power was supreme. In reinforced concrete, matters were not so simple, for where the designer was a specialist firm, it was the engineer or architect who then became the principal or client, and the specialist firm assumed his duties and responsibilities, and certain additional responsibilities into the bargain.

The intrusion of the specialist firm.—The point which concerned them in the paper was the case where the assistance of a specialist firm was called in either by the client direct or through his technical adviser. There were two categories of specialist firms (A) those which derived their profits from the exploitation of a patent system of construction, and (B) those which derived their profits from the exploitation of a patent form of reinforcing material. The firm which exploited a patent system of construction combined divisions 1 and 2 previously referred to—i.e., the supply of the design and its execution. The execution was generally carried out by contractors specially licensed by the specialist firm, whose work was approved by the latter. On the other hand, the firm which exploited a patent form of reinforcing material combined divisions 1 and 3—i.e., the supply of the design and of the necessary reinforcing material. In this case the execution was generally tendered upon by non-licensed contractors, with sometimes, however, a certain restriction in their selection. Where a specialist firm executed the work itself, it came within the category of a licensed contractor for that special contract. The logical method would doubtless be for specialist firms to combine all three divisions, and supply design, execution, and materials, thus doing the whole work throughout themselves. But it was obviously impossible, under present conditions, for any single firm to keep up the enormous organisation which would be necessary to carry out contracts simultaneously in all parts of the country. Each method of exploitation had its use and advantages, and the selection of method by the client would depend on circumstances and on local conditions. There was room in this country for all methods and systems, and no doubt in time these would settle down into specific grooves, so that certain classes of work would be carried out on certain lines, and some co-relation would be established between the various firms and systems which would apportion the work to the interests of all concerned.

Responsibilities.—It would be conceded as a general principle that responsibility should be confined to duties undertaken. It was illogical, for instance, to fasten responsibility of execution upon a specialist firm which was not afforded the opportunity of control and supervision of work. It was unfair to expect this firm to make good any mistakes in quantity of material which might arise in estimates; and yet this was continually occurring. The client, when ignorant of the method of construction he was about to adopt, naturally looked to the specialist firm for a guarantee. A refusal to accept this guarantee would frequently lose the work, because the client imagined that the firm had no confidence in its system. The real reason for refusal was that no provision was made for supervision, and, as so much depended upon the actual work upon the site, no specialist firm which valued its reputation would accept such responsibilities, unless it was in a position to supervise. Clearly responsibility in this case should be accepted by the contractor, but he would frequently refuse, under the impression that everything depended upon the system adopted; naturally, if he could avoid such liability he would do so. The ordinary responsibilities of a specialist firm should be limited to the design and to the quality of the reinforcing material, when the latter also was supplied. When a full guarantee involving construction was exacted, the firm should stipulate for proper supervision and control over the contractor by one of its staff appointed as resident engineer, with suitable remuneration for such service. The question of responsibility, therefore, should be clearly defined at the outset of every contract, and those specialist firms which did not carry out contracts themselves should stand together in resisting the imposition of guarantee for work which they could not control, or otherwise any resulting disaster would affect the reputation of all. In the case of

Digitized by Google

firms which exploited (A) systems of construction, the responsibilities were of course more clearly indicated. The firm guaranteed its design and the licensed contractor guaranteed its execution. The reinforcing material being purchased by the contractor, the latter was responsible for it, but had the right of rejection. In this case the specialist firm occupied the place of the technical adviser, and risked its reputation like the latter, but not its pocket, except as regarded the guarantee of design pure and simple.

Data.—The client, the lecturer thought, should remember that the more complete information he supplied to the specialist firm he employed the more expeditiously and intelligently would his plans be prepared. Particulars concerning the loads to be carried, nature of soil and foundations, materials available near site, were essential. Architects should say whether the specified loads included the dead load or not; the tendency to omit this information often placed reinforced concrete in unfair comparison with ordinary steel joist construction. The nature of the test load should be specified at the outset. Sufficient attention was not paid to the question of fire protection. The nature of the aggregate, whether sharp or smooth, a specification of the cement and its setting time, the breaking and elastic limits of the steel, whether concrete should be mixed wet or fairly dry, &c., should be stated. The height of the floor above ground when only one floor had to be supplied would materially affect the price, and even the scantlings of available timber for centring will, if known beforehand, enable the beams to be so designed as to utilise it without waste, and thereby effect a saving. So that no details were so insignificant as to be despised. A point on which confusion often arose was the factor of safety. A comparison of competitive designs on a large contract would frequently reveal an extraordinary diversity in the factors of safety when these were reduced to the same denominator. The client should at the outset clearly indicate whether designs were to be tendered upon by contractors selected by him or by contractors associated with and approved by the specialist firms. This saved time and useless correspondence, and would enable the latter to give detailed information to contractors with whom they were not associated when these were specified by the client, which was not necessary in the case of contractors with whom they worked together. Clients should, in justice to competitors, place them all on the same footing, and any deviation from this rule should be resisted by competing specialist firms, who should co-operate in refusing to submit designs under conditions which did not give all the same chance.

Preparation of designs.—When inviting competitive designs the client should not ask for too many details at the outset, but should be content with diagrammatic plans which indicated the system proposed sufficiently clearly to enable him to make a selection. He should remember that plans were generally prepared free of charge by specialist firms, and consideration should be shown by not throwing too much useless work upon them. The present tendency was to require too much detail before the selection of a specialist firm was made, and this was particularly irritating when schemes were only in their initial stage. It was a regrettable fact, to which attention must unfortunately be called, that designs obtained from one specialist firm were sometimes sent by the client to a competitive firm to see if the latter could improve upon them. A design was the property of the designing firm and should be respected as a privileged communication until the client had acquired it on the terms on which it is submitted. The communication to a rival was a breach of faith which the lecturer suggested should be met by a joint undertaking by specialist firms to refuse work offered under such conditions.

Estimates.—Generally the client was in a tremendous hurry for his plans. Hurry meant mistakes, and for these the specialist firm had to suffer. The modern system of bustle and strenuousness, so much admired in another hemisphere, was peculiarly unsuitable for reinforced concrete, for in this, more than in any other branch of construction, more haste meant less speed. Engineers and architects who took months to mature a plan expected very often full detailed plans by return of post. Specialist firms should resist such demands, and refuse work for which a proper time allowance was not made, rather than risk a disaster which may affect all concerned in the industry.

Differentiation of work.—There was a present tendency to lump all classes of work together, and to invite tenders on the whole contract, even in cases where the reinforced concrete portion is relatively insignificant as compared with the remainder of the contract. It could not be too strongly insisted upon that reinforced concrete was a separate subject altogether, and that the portion of a contract which concerned it should be scheduled apart from the other portions of the same contract, and separate tenders invited upon it. In the case where the reinforced concrete portion was the most considerable part of an important contract, the other portions might form sub-contracts. But it was essential to differentiate the reinforced concrete from the rest, so that the estimates from specialist firms might be compared together on their merits without being affected by other portions of the contract. A satisfactory tender would frequently be spoilt by the addition of excessive sums for other portions of the work with which the contractor was not familiar and for which he provided too large a sum to cover himself against possible loss. This occurred specially in cases where prices were sent in hurriedly and the specialist firm or the other contractor had no time to obtain sub-estimates from contractors versed in that class of work.

Payments.—It was desirable that specialist firms (B) which supplied reinforcing material should receive payment for this and for their designs, if these were charged for, direct from the client, and not from the contractor as at present. This would avoid the frequent unjust detention of moneys for materials supplied to the contractor by the withholding of the necessary certificate of payment when the contractor had failed to satisfy the engineer or architect.

Cheapest not always the best.—This was perhaps a trite saying, but in no case was it more applicable than in the case of reinforced concrete. The tendency in this country was to go for the lowest tender without reference to the status of the contracting firm or the quality of the design. The cheap tender which cut out the offers of good firms might frequently come from an unsatisfactory contractor or from one who was ignorant of the difficulties he had to encounter, or who desired to get the work at any cost as an advertisement. The carrying out of the work under these conditions became a source of expense and worry to the client, and he was likely to regret his selection.

Local Government Board loans.—The London Building Act now in course of revision would, it was hoped, be so amended as to give an impetus to construction in the Metropolis, which had hitherto been restricted by regulations which were drafted when reinforced concrete was an unknown method of construction: but unfortunately, difficulties were still experienced with the Local Government Board in respect to satisfactory loan periods for reinforced concrete structures, which it would not sanction on the same terms of repayment as other forms of construction such as brick, timber, &c.

Mr. F. E. Wentworth Shields, M.I.C.E., in opening the discussion said that reinforced concrete had brought into being its own specialists, who were of two kinds, viz.: the "designing" and the "merchant" specialist. They had done a great deal of good work in this country. The paper from its general tone might, he thought, be called the bitter cry of the specialist. A firm of architects who wished to design a reinforced concrete building and who had not a very intimate knowledge of the subject, put themselves in the hands of such a man. They referred contractors to him, and he told them how much the work would cost to execute. When the work was finished the contractor, says the story, discovered that the price he had been given was altogether too low, and he accordingly applied to the architects to make up the difference. The concrete specialist had done most magnificent work, but he was bound to disappear, at any rate as a mere designer. He was owed a debt of gratitude for the enormous lot that he had done to push forward this material. But he would go as surely as history repeats itself. When steel girders first came in, people were extremely suspicious as to whether they could carry such loads as were claimed for them. There arose a number of engineers who made a speciality of the practice and theory of their subject, and they were consulted by architects and contractors. But in course of a few years every young architect got familiar with girders, and the specialist died out. So in the same way the time will come when the architect and engineer will prepare his own design for reinforced concrete work. The fact that most systems are in the hands of patentees might seem to point against the accuracy of this anticipation; but that is really only a minor obstruction—some of the patents are already expiring, while others are being contested in the courts. The necessity for giving full information about failures was a most important point. Indeed the Concrete Institute should investigate all such cases, and should lay down rules which will prevent them, and in the light of which they could say that providing their rules were followed they could guarantee a life of thirty years.

Digitized by Google

Mr. A. ALBAN H. SCOTT said one would think from the author that the professional services of architects and consulting engineers would shortly be entirely dispensed with, as the concrete specialists will carry out all the duties formerly performed by them, excepting apparently the settling up of accounts and differences between the various people engaged upon any work. During the course of the paper the word "client" was used indiscriminately. A "client" is really the person who pays for professional services, and in all cases this must be the building owner. It is stated that the logical method would doubtless be for specialist firms to combine the three divisions of supplying the design and materials and executing the work; but this is surely illogical. It is against all accepted principles, and can never to any great degree come into force. A large number of the difficulties put forward in the paper are very easily overcome by adopting the simple process in use for all other kinds of work—namely, that the architect prepares the whole of the plans necessary for obtaining tenders and that the quantities are taken off by him or his quantity surveyor, and that he should calculate the whole of the reinforced concrete work, the same as for every other part of the work, and provide in the quantities for the necessary amount of steel and other materials required. Tenders should then be invited from any responsible builder in the usual way. In the bill of quantities an item should be inserted for the payment by the builder of the patentees' fees, and these should be treated exactly the same as the quantity surveyor's fees are treated when inserted in the bill of quantities. The patentee would then be in exactly the same relation to the client and architect as the quantity surveyor. After the tenders have been received and examined the architect or the surveyor should get into touch with the patentee whose system it is intended to adopt, and should at this stage, and not before, ask the specialist for detail drawings showing his exact suggestions for the adaptation of his system. The quantities can then, so far as the steelwork is concerned, be revised if found necessary. Under these conditions no question of deficient quantities can be raised, no unnecessary trouble is given to the patentees, and—perhaps the most important item of all—there is no competition between different systems, because immediately there is such competition it is the tendency of all patentees to reduce the amount of their steel and concrete to the very lowest point possible. Provided the calculations are made all on an identical basis the amount of steel required by the various systems is for all practical purposes the same, and this also applies to the labour required. This method had always been adopted by his firm, and, Mr. Scott said, had always, in both small and in very large works, proved eminently satisfactory. With regard to the question of responsibility, although under common law the responsibility is already clearly defined, yet in all forms of contract it is advantageous to have a special clause inserted for reinforced concrete work that the builder is entirely responsible for the materials and workmanship, and that the patentee or the designer of the reinforced concrete work is responsible also direct to the client for any faulty design. It is mentioned that it is not an unknown thing for a "client" to merely indicate four lines to scale on a plan and ask for a warehouse. Presumably it is meant that the so-called client wishes for plans and estimates for a warehouse. No architect would lower his dignity to do such a thing as this, and therefore the word "client" in this case is no doubt used to indicate the building owner. This only emphasises the point that a so-called specialist in reinforced concrete work should not act in the capacity of architect or engineer, as he is certainly not competent to put the windows, doors and other accessories in their proper place.

Mr. E. FIANDER ETCHELLS, Phys.S., remarked that the contractor who thinks to-day of strength alone not counting the cost would most probably find himself in the bankruptcy court. Everyone knows how often an order has been missed because some person less scrupulous or more daring has cut down his thickness and cut out some of his reinforcement, and so won the coveted order. Unrestricted competition and each man his own Concrete Institute does not make for sound construction or fair prices. At present the man who will take the most risks gets the most business. The Concrete Institute should consider whether the R.I.B.A. joint committee's report should not be adopted with such amendments as might prove to be necessary. The position of the engineer in the case of failure was of great importance. In France, he understood, they put the designer in prison. There was very ancient legal precedent for far more drastic measures in the case of bad building.

Mr. G. C. WORKMAN thought it was quite fair that the specialist designer should be held responsible. Often a specialist's work was handicapped by the meagreness of the data supplied. For instance it was sometimes necessary to guess at the floor loads, and they were rarely given the bearing capacity of the ground; in consequence there are wide differences in the estimates. Then such vital questions as the working stresses in the materials and the factor of safety are controlled to a great extent by personal opinion. Many architects fail to realise that they should allow the specialist reasonable time for preparing his work. They should understand that hurry means mistakes in the preparation of estimates, and other work.

Mr. J. MUNRO considered it was too early to formulate statistical data as to the value of reinforced concrete work in this country—another decade will have to elapse. The responsibility should, according to his view, be absolutely borne by the specialist, for an architect has not enough time to accept it. If specialists make too much fuss on this matter the architect will send them to perdition. Eventually no doubt the architect will have all the details at his fingers' end and will assume all the responsibility. In every specification, i.e. in every estimate given by a concrete firm, there ought to be a definite sum earmarked as discount for the builder, who has a lot of things to see to and who earned 5 per cent. If the total is not a serious one there is no reason why it should not be amalgamated in the general bill.

Mr. MORITZ KAHN stated an Englishman used a reinforced concrete type in 1831 when Moniet was a small boy. Reinforced concrete was indeed rocked in the cradle between the North Sea and the Irish Sea. Undoubtedly too much competition was prejudicial to the interests of the owner, for it was he that eventually had to pay for the loss incurred by firms in endeavouring to secure business. As to responsibility Mr. Kahn argued that if an engineer prepares a design he should be held responsible for it. If a contractor supplies the labour and materials he should be responsible for such portions. All the reinforcing steel could easily be tested before use. Any accident must result from faulty design or faulty labour and material. Drawings can always be checked, and if these are found correct the fault must lie with the execution. In his opinion Mr. Serraillier had asked too much in requesting the client to become liable for the payment of reinforcing steel supplied to the contractor. This, however, was a trade problem rather than a professional one. It was undoubtedly wise sometimes to investigate the standing of a contractor. If it proved unsatisfactory the refusal to supply him with reinforcement would probably have the twofold advantage of saving a possible financial loss and a future accident. One of the disadvantages which competent firms had to labour under was the way in which their designs were passed around.

Professor HENRY ADAMS thought that the greater part of the paper could not be gainsaid. On the subject of responsibility the law seemed to be that a person was not responsible for errors of judgment but that he is responsible for neglect. The differences in the factor of safety correspond to the differences on the Stock Exchange—taken as a whole the stocks average under 5 per cent. It is a factor against all possible contingencies, and therefore to some extent against the unknown. In practice it is impossible to rely implicitly on the workmanship. In the case of failure the fault is traceable to workmanship rather than to design.

Mr. EDWIN O. SACHS in summing up the discussion expressed his belief that certain abuses which are to be found at present would gradually disappear. He did not share the views expressed as to the impending extinction of the specialist. In his opinion it would be more in the nature of evolution. The architect will design more carefully; the specialists will get good specifications, and the makers of such things as bars will make them to standard specification. The architect will know exactly what he wants. In fact the specialist may look forward to enjoying an easier time. Everyone should be very grateful to the specialist for his pioneer work, though it ought really to have been done by the architect and engineer. In the case of failure publicity would be an advantage, for the unknown is always worse than the known. In Germany and Austria, he believed, unfair competition was treated as a criminal offence. In his opinion builders should receive a specific sum, say 5 per cent., for their trouble in connection with such work as reinforced concrete. But builders often tried to make considerably more out of the specialist.

Mr. SERRAILLIER then replied to the various points and the meeting closed.

NOTES AND COMMENTS.

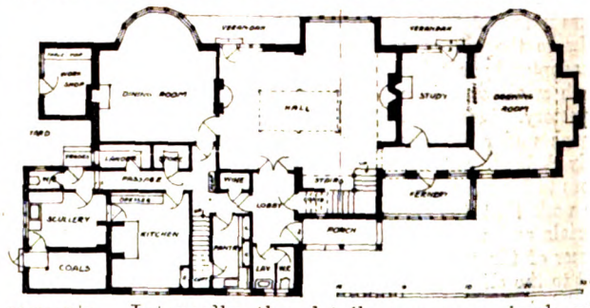
We have been asked to explain what is meant by the "zero-potential" system of ventilation to which we referred last week. The term, we believe, is somewhat new, having been coined—or rather transferred—from the language of electrical science by Dr. Shaw, to describe the system of ventilation in which both inlets and outlets are under control by the use of fans or other means of applying power to force in fresh air and extract foul air. If the air is being sucked out by the same amount of power that it is being pushed in, the system is neither plenum nor vacuum, but a combination of the two, and this Dr. Shaw christened "zero-potential." Although the name is new, the system is not, as it has been in use on the Continent for more than a quarter of a century. In this country, despite its excellence as a system, it has been very little used, chiefly because the British public has not yet learnt to pay sufficiently for really good ventilation.

The interesting church at Worth, in Sussex, is the subject of a monograph by W. P. B. Stebbing, F.G.S., recently issued by the Essex House Press, and giving a very full account of its architectural history, all the more valuable for the views included showing the appearance of the church before its restoration. There is no doubt that both from its plan and the character of its masonry, Worth Church is an example of later Anglo-Saxon architecture, and we agree with the author that it would be incorrect to assign to it an earlier date than A.D. 1050, the period when, although William of Normandy had not yet fought the Battle of Hastings, the influence of Norman architecture was making itself felt in the buildings of this country. It should not be forgotten that the Norman period in English architecture commenced before the year A.D. 1066, hence there is no reason to suppose that an apsidal east end and Anglo-Saxon masonry may not be contemporaneous.

The excellence of the illustrations in *Country Life* is so well known that the second half-yearly volume of 1908 needs no recommendation. To architects its chief interest and value lie in the continuation of the remarkable series of illustrations and descriptions of the country homes and gardens of Great Britain that has now been for some time in progress, and of which are included in the present volume Bamburgh Castle, Northumberland; Batemans, Sussex; Bridge House, Weybridge; Cefn Mably, Glamorganshire; Cirencester House, Gloucestershire; Clumber, Nottinghamshire; Dorfold Hall, Cheshire; Easton Neston, Northamptonshire; Fawsley Hall, Northamptonshire; Gilling Castle, Yorkshire; Haiswell Park, Somerset; Harrowden Hall, Northamptonshire; Hestercombe, Somerset; Kirklees Park, Yorkshire; Parnham House, Dorsetshire; Plas Mawr, Carnarvonshire; Rainham Hall, Norfolk; Studley Priory, Oxfordshire; Tredegar Park, Monmouthshire; Westbury Court, Gloucestershire; and Wolterton Hall, Norfolk.

Tariff Reform, when it comes, if it does come, may introduce British architects to a like mild excitement to that which is agitating our Canadian brethren at present. It seems that architectural plans and specifications are dutiable articles in Canada, and that there is going on a considerable amount of smuggling in such contraband from the United States, which is the matter of serious complaint on the part of Canadian architects against the indifference and neglect of the Government officials to enforce the payment of duty. The gravamen of the present discontent seems to be that there is no reciprocity; that Canadian plans never, by any fortunate chance, find their way into the United States, where the duty is high and those who have its enforcement in charge understand that the law is made to be enforced.

Protection by tariff is usually understood to be the weapon employed by States to defend their industries against stronger and abler competitors in foreign countries. We can hardly imagine that Canadian architects are so far inferior to their fellows in the United States as to render it necessary for a paternal Government to protect them by a high tariff—indeed, the fact that the United States places a high duty on Canadian plans is a tribute to the ability of Canadian architects.



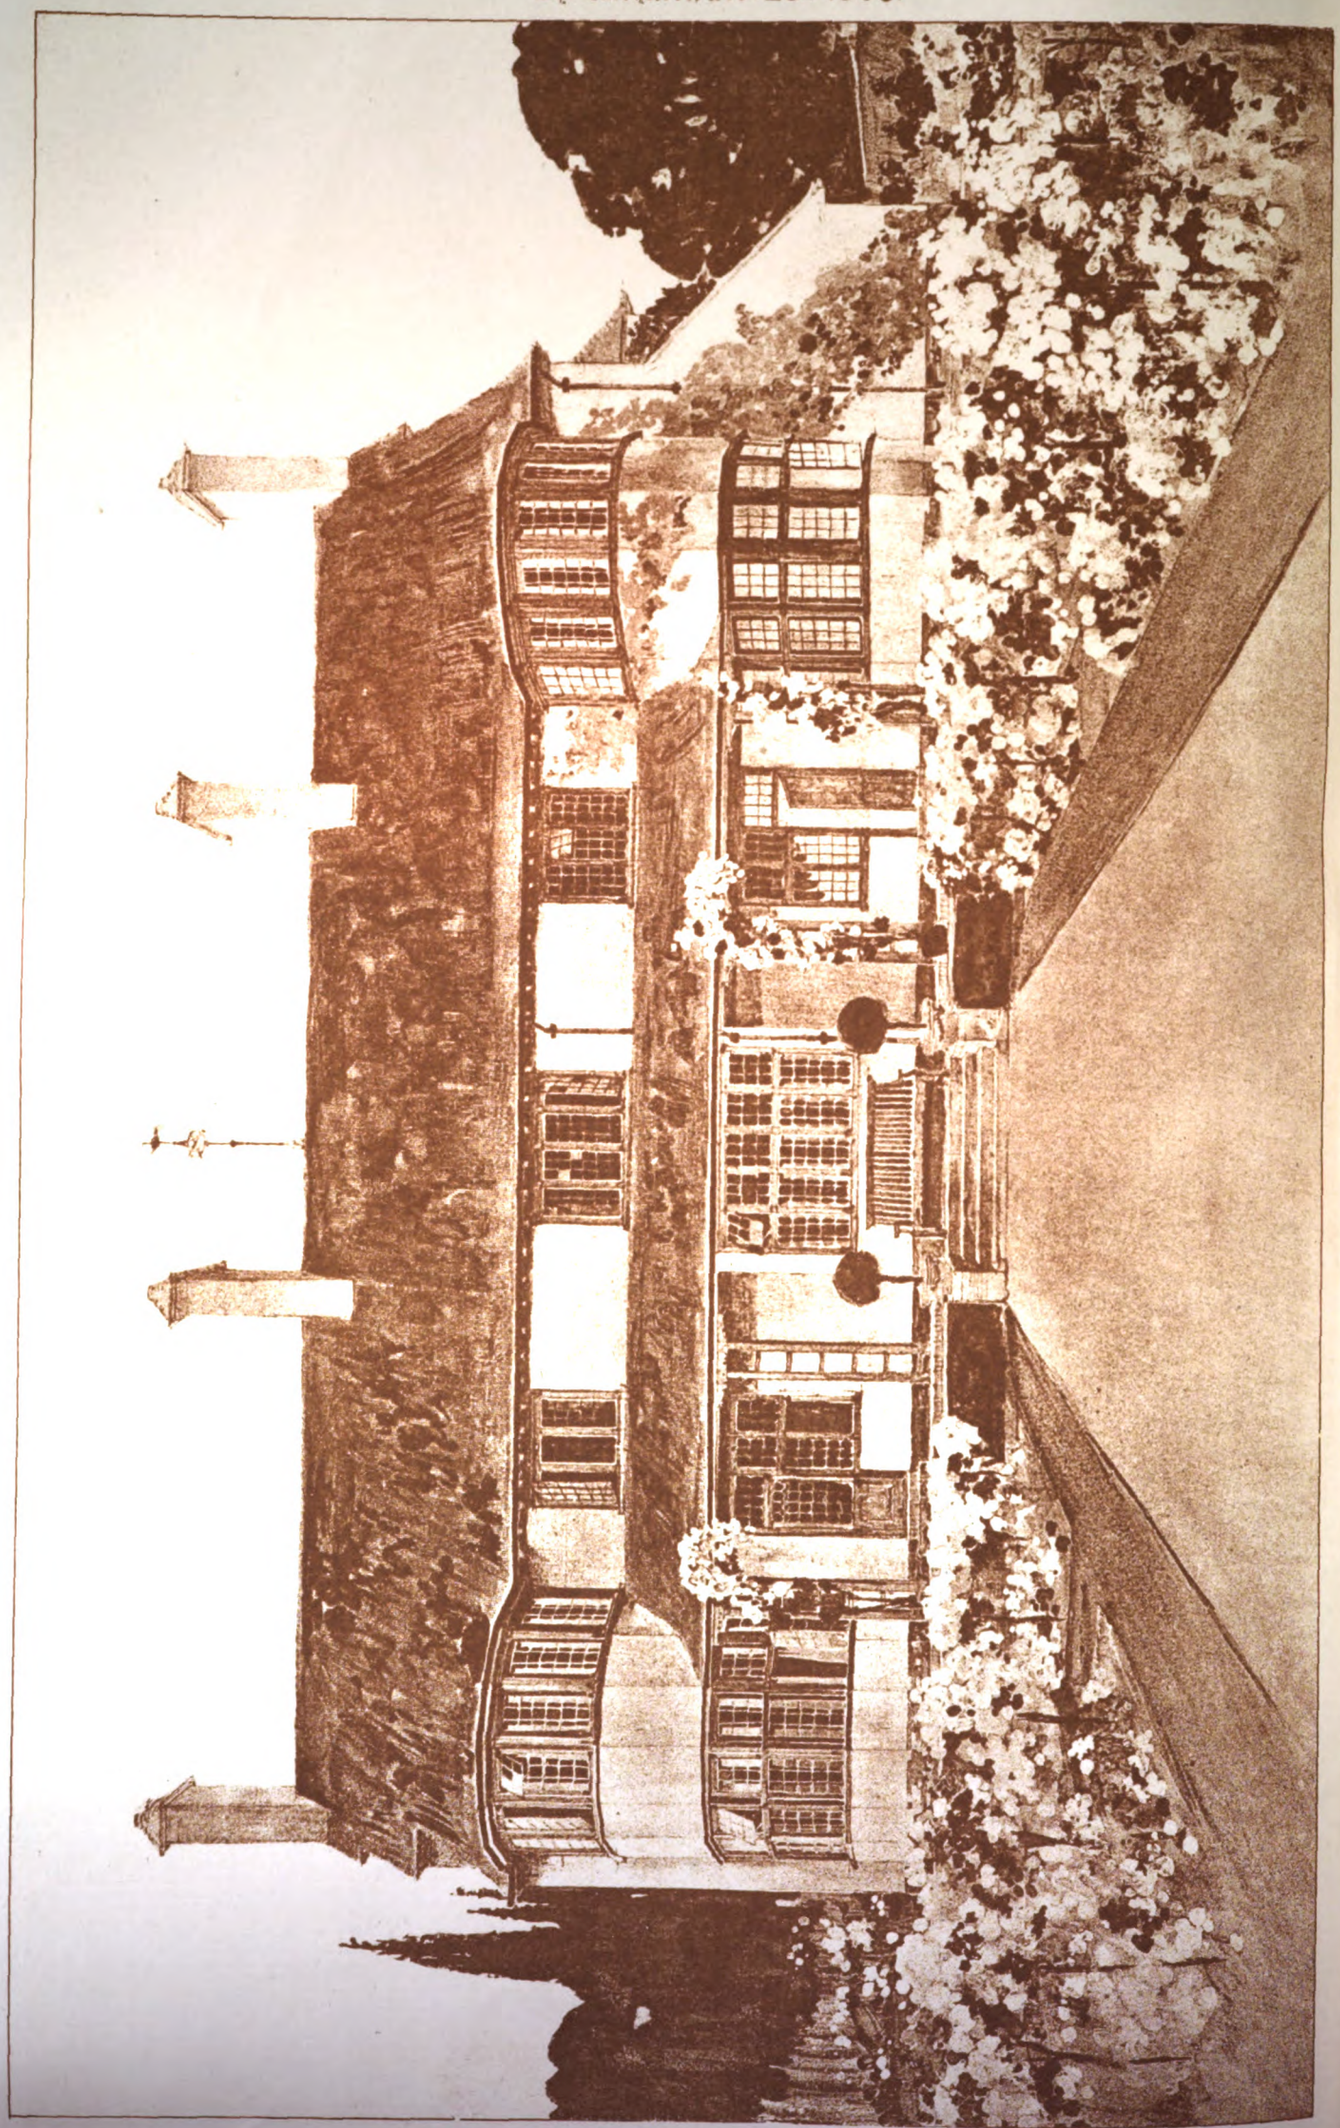
ILLUSTRATIONS.

DESIGN FOR GLAMORGAN COUNTY HALL, CARDIFF.—ELEVATIONS—DETAIL OF MAIN FRONT—PLANS.

This scheme shows a building well set back from the boundaries of the site, as it was felt that the buildings erected in this park should be seen from all sides. The Portland stone elevations are therefore carried round and treated in a simple manner, the enrichments being reserved for the façade to the avenue. The plan is arranged round a single area, which lights the corridors, the rooms being lit from the outside. The Council chamber, with its committee and members' rooms, is placed on the first floor, and is approached by means of the grand staircase and a lift near the entrance; this arrangement ensures the necessary privacy of this department. The office departments are placed on the ground floor, where they are readily accessible to the public and each other. The provision of the basement was a condition of the competition, and is utilised for the caretaker's apartments and for storage purposes. The features of the façades are suggested by the plan, and are designed to be in character with the municipal buildings in the same avenue, but are kept simple, as this building is of secondary importance. The architects are Messrs. Nicol & Nicol.

HOUSE AT SUNDRIDGE PARK.

The site for this house has its main interest in the rear, where the morning sun is, so the principal rooms all face the garden, excepting the drawing-room, which has windows to the front as well, to catch the last rays of the afternoon sun. One of the principal conditions imposed was that there should be a hall large enough to take a billiard-table, and so arranged that servants could go upstairs and answer the front door without crossing the hall. On the first floor are seven bedrooms and dressing room, two of the bedrooms being kept in a separate wing over kitchen and offices for the use of



servants. Internally the details are very simple with little enrichment except a Bankart ceiling to the hall. Externally the walls are rough-cast, with a hand-made tiled roof. The builders were Messrs. Pearce Brothers, of Bromley. The wrought-iron casements and glazing were supplied by Messrs. Henry Hope & Sons, Ltd. The woodwork internally and externally was finished with carbolineum, the architect being Mr. C. W. B. Quennell, F.R.I.B.A.

NEW CLUB HOUSE, MARKEATON.

This building is being erected in a commanding position upon the new links acquired by the Derbyshire Golf Club at Markeaton, near Derby, which will be opened in the spring this year. On reference to the plan it will be seen that in addition to the ample rooms to which the members have access, there are also the private quarters of the professional and an office for the secretary. All the main rooms have wood-block floors, with the exception of the lavatories, and will be heated by low-pressure hot-water system, which is in the hands of Mr. A. J. Brooks, of Derby. The principal elevations are covered with rough-cast above a brindled brick plinth, and the roofs covered with hand-made sand-faced tiles. The contractor is Mr. J. H. Fryer, of Derby, and the architects are Messrs. Thorpe & Fryer, of Derby.

SIR CHRISTOPHER WREN'S OFFICE.

OUR illustration of a now vanished corner of St. Paul's Churchyard shows the house which tradition says was at one time the office of Sir CHRISTOPHER WREN, and which is also interesting both as an example of our English version of Renaissance and from the peculiar rhythm of its composition. During part, at any rate, of the time that St. Paul's was in progress, WREN had an office in Scotland

[*Photo by Bolas, London.*

Yard, for his pupil's copy of "Vitruvius," published in 1684, contains the autograph signature, "NIC. HAWKESMOOR. At Sr. CHR. WREN's, in Scotland Yard." HAWKESMOOR went into Sir CHRISTOPHER WREN'S office in 1684, and probably purchased his "Vitruvius" soon after its publication. The photograph from which our block was made is an enlargement from a snapshot by Mr. S. B. BOLAS.

The Whittingham Asylum Competition has been decided in favour of Messrs. Sykes & Evans, 7 Chapel Walks, Manchester, to whom the first premium of 100*l.* has been awarded. The second premium of 50*l.* and the third of 25*l.* have been awarded to Mr. Percy D. Lodge, 34 John Dalton Street, Manchester, and Messrs. Appleyard & Quiggin, 67 Lord Street, Liverpool, respectively. There were eighteen sets of designs. The competition was for an annexe for about 700 pauper lunatics to be erected on the asylum estate at Whittingham, near Preston.

ROYAL ACADEMY LECTURES—SCULPTURE.

THE first of the four lectures delivered by Mr. W. R. Colton, A.R.A., Professor of Sculpture in the Royal Academy, was described as "Preliminary—to the Sculptors of To-morrow." In his opening remarks he deplored the fact that there was now a craze for the acquisition of wealth, while science, art and literature were held of little account. This must inevitably tend to the lowering of the mental standing of the nation. Our schools of art possess one of the most satisfactory systems of teaching in Europe. By it the retention of individuality in every student is fostered. Students of sculpture, however, were handicapped by the difficulty of instructing them in the large practical side of their work. Sincerely to be pitied was the dexterous young student who starts his career after being petted by his masters and assisted by encouragement. He has most likely gained numerous prizes, and (not unnaturally) has come to regard himself as something of a great man. He must now sweep all this on one side and stand once again lonely and deserted at the beginning of things.

The present day is a time full of promise for sculpture—perhaps, all things considered, the greatest time for sculpture that has ever existed. Nevertheless there was considerable danger in the tendency to go back to the archaic and to the barbaric. There is an impatience with those refinements of art that have ever increased since art began. The philosophic in art has been pushed on one side by the passionate and the sensual. It was deeply to be regretted that there are not half a dozen generous and sufficiently rich patrons of ideal sculpture in England. It was a reflection upon the nation to have to say that there was not at present a single artist living upon the production of ideal sculpture alone. There were certainly beautiful things to be seen in this country, but they were mostly to be found in museums where they become wearisome and are not sufficiently near for us to get to love them. What proclaims itself loudly or shouts is poor sculpture, poor both in taste and execution. The test of the real in art is an increase in appreciation; the greater the familiarity the more precious should an object become.

One of the great dangers besetting the path of the young sculptor was that he might be ensnared and enchanted by coloured figures. He may have more the feelings of a painter than of a sculptor, and thus lose the highest in both. As the head of Medusa turned flesh into stone by its gaze, so the true sculptor should turn clay into flesh by his touch. The use of colour seems rather to indicate that this high result has not been achieved. It was to be doubted whether the finest sculpture was ever coloured at the wish of the artist; it might be so treated at the command of an emperor or at the suggestion of an architect. No sculptor could ever be really willing to see his noblest work so used. With second-rate sculpture it would be different. It was common knowledge that coloured figures were employed by the Assyrians, Egyptians and Greeks, but this particular class of work was intended to impress the common people. The deity represented was the owner of the temple rather than an architectural part of it; the figure was so large as to be out of all proportion with the building. On the other hand, the absence of colour in a statue confers on it that quality by which it may be looked upon without arousing any of the sensual feelings that may be inspired by the nude on canvas. The temptation to indulge in colour has before now heralded decay. Its use distracts attention from the higher points.

Mr. Colton in his second lecture continued his remarks under the heading "Preliminary—to the Sculptors of To-morrow." He deplored the tendency nowadays to regard sculpture from an incorrect standpoint. Sculpture brutally executed is called power and passes for the highest in the art; all that is rough hewn is supreme. It is true a giant carved out of a mountain of living rock is, or ought to be, impressive by its sheer ruggedness; but to reduce this to life-size is to put to scorn the art and striving of the past centuries and is unthinkable. A very modern development is mutilation. It has been discovered that to lop off an arm or two arms, a leg or two legs, greatly enhances the value of the artistic production. Students must bear in mind that sculpture should never try to express the frivolous or domestic, nor descend to the absurd and grotesque; it should be an expression and realisation of an idea which should, as far as may be, be divorced from the matter of fact. In decorative work its most proper place is perhaps the fountain with its many beautiful and delicate associations.

The most important works in this country had been too curbed by committees, or sometimes instead of a committee

Digitized by Google

it is an architect that has to be faced. It was not realised by these people how important it is that the prime intention of the artist should not be frustrated and the whole thing be made of negative value. It is a case of each man to his craft, and the creation of a memorial should be left absolutely in the hands of its creator. But this, there was good reason to hope, would with passing years become less and less a difficulty. For the sculptor and architect are joining hands, as they should, in their endeavour to produce fine work. The architect who does not wish the sculptor to have anything to say as to the arrangement of the work will go to the architectural sculptor, a term that always sounds something of a misnomer.

There were many points in the practical side of his work that the young sculptor would only learn by experience. If possible, the sculptor should not undertake the foundations of his work, as they were such an unknown quantity. And it is better to put the responsibility on somebody else's shoulders, such as those of the contractor for the pedestal.

The Greek seems always to have had a desire for thoroughness. The figure or group that was to be placed prominently a long way from the eye was executed with the same conscientiousness as if it were to be seen close to. The modern European idea of scale of texture of surface is opposed to this. It is now thought sufficient if the surface is left rough hewn so that an effect of finish is given to it at a distance. More than this, the modern doctrine is that this roughness gives more power when seen from afar. It would be interesting to know of any case where the Greeks were satisfied with this. Their end seems to have been that their work should not only have the appearance of completeness, but as far as they could make it should be really so in fact. Our museums and galleries contain works which were originally placed a considerable distance from the eye, but their finish is absolutely perfect. The Parthenon frieze was never done justice to before it was placed in the British Museum. It was safe to assert that a completely rendered work need lose little from its position, provided that the sculptor has learnt from the old masters to execute broadly enough. No doubt the love for the rough-hewn in sculpture is partly to be accounted for by the diminishing payment which is made in inverse ratio to the height of the statue. Another reason is the urgent demands from architects and committees for rapid completion and delivery. There is one thing to be said in excuse, and it is that modern architectural work, especially in our great cities, will not live one fraction of the time that will be enjoyed by work in a purer climate.

These considerations should suggest many thoughts of interest regarding sculpture in conjunction with architecture and the beautifying of cities with sculpture in relief and in the round.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Henry Tanner, jun., vice-president, in the chair.

The HON. SECRETARY announced the fourth spring visit, fixed for February 27, to the National Society's Training College, West Hampstead, members to meet at the building at 2 P.M. A visit will afterwards be paid to the L.C.C. Board school at New End, Hampstead.

The following gentlemen were elected members:—Messrs. L. M. Yetts, G. H. N. Inman and E. V. West.

Mr. A. L. N. Russell was presented with a book prize, value 3*l.* 3*s.*, gained in connection with the A.A. photographic competition.

Mr. A. NEEDHAM WILSON read the following paper, entitled

The Press and Architecture.

I confess that I approach the subject of this paper with a very considerable amount of diffidence and under conditions of more than usual difficulty. For one thing, I feel that it would have been infinitely more advantageous to have had the views of a Pressman, and one intimately acquainted with that portion of the Press which is accustomed to gauge the tastes of the vast reading public; not to pander to the tastes that are vitiated, but strong enough to lead, to guide and to instruct. For another thing, I feel that latterly we have witnessed a vast change in the attitude of the Press to our profession and its productions, and the present moment is one of such paramount importance, a moment so pregnant with great possibilities, that since it was ordered that the subject should be dealt with by an architect it should be handled by one who had greater influence and whose words would carry greater weight in our profession.'

I am so convinced that the moment is fraught with big events for architecture, in this awakening of the powerful English Press. I am so anxious that the impulse should be well directed. I am so desirous that the opportunity should be favourably seized upon, and without false modesty am so conscious of *my* incapacity to deal favourably with it, that I can only express the hope that the question may receive more capable attention at other hands than mine.

Before I proceed I think it is advisable to clear the ground somewhat, and I wish it to be understood that I do not include the professional Press in my remarks. We architects, in my opinion, cannot overrate the debt of gratitude owed to the professional Press, which has done so much to promote the best interests of our art, to foster its appreciation, and to advance its progress in the best channels. It would be an ungracious act on my part if I did not pause to acknowledge the help and assistance which we as an Association have received from the professional Press and all those connected with it, from the editors to those gentlemen who report what are only too frequently, I fear, dull, lame and halting speeches in this room. No, we have little to complain of in our professional Press, which indeed does not come within the scope of my paper.

I am fully aware of another serious difficulty which I see looming ahead. In advocating the acknowledgment of architecture I shall be accused of advocating the acknowledgment of architects. I plead guilty, for that is precisely what I shall do, holding that the one is a necessary corollary of the other. If I am to be accused of advocating the advertising of architecture and architects, I shall not plead guilty, holding, as I do, that such exhibitions in the daily Press are not conducive to the best interests of our profession, and are open to justifiably caustic comment. I have no doubt several instances will occur to the mind, and I leave it to others to say whether such published interviews are calculated to promote either the dignity or the best interest of our art.

My difficulty to-night is accentuated by the impression that the daily Press has a tendency to rush from indifference to the other extreme, and thereby offer a temptation to the young and struggling man to make a desperate attempt to escape from the trammels of obscurity, and to launch himself on a career of fame. The process is simple. Hatch up a wild cat scheme, preferably connected with a public building, dish it up in as splashy a drawing as you can, and send it to the—well, a daily paper. Do you think a dome would look well on Westminster Abbey? Send it to the Press. Why not rebuild the Bank of England as a skyscraper? Send it to the daily Press. Cover in Trafalgar Square with steel and glass—send it to the daily Press. Cannot you find a site for an unnecessary public building? Then put it on an artificial island in the river and send it to the Press. Presumably these perpetrations are forwarded to the journals by their authors, for it is difficult to believe that editors themselves search out these things with the idea of interesting their readers.

This suddenly awakened zeal in architecture has taken another strange phase of recent years, partly accentuated by the garden city and cheap cottage craze, and such incidents as the settlements in St. Paul's Cathedral. So much public attention was drawn to these matters that the reading public realised for the first time that there existed a class of individuals known as architects, and the doubtful privilege of the "interview" was extended to members of the profession. If I remember rightly, one of the first of these appearing in a pushful morning paper was not unwarrantably made the occasion of some extremely severe comments by brother architects. Then when three men who were legitimately entitled to be consulted upon the condition of St. Paul's came so prominently before the public eye, there seemed to be quite an unseemly rush to express an opinion, not only on this subject, but on many others. The number of unknown men with opinions of no value whatever whose names appeared in print at the time was rather astonishing. The public read with awe of the opinion of Mr. Brown, the "well-known architect," of Mr. Jones, "the celebrated architect," of Mr. Robinson, the "famous" architect—read and was none the wiser. Shade of Vincent Crummles, how do these things get into the papers?

It is unnecessary to take you through the subsequent stages, but it seems to me that this Press period culminated recently in a sort of symposium in an evening paper following on a series of articles by a certain professor, and sup-

Digitized by Google

posed to aim at the discovery of the finest building in London. The result must have been somewhat bewildering to the reading public if they read the opinions at all. And if they came to any conclusion, it must have been one of contempt. Still the attempt was on the whole commendable, as it probably led many to realise for the first time that fine buildings did actually exist in London. This is something achieved by the Press, though whether as a result architecture has been advanced is open to question, and for architects there seems only a step between this kind of thing and the advertisement columns.

This tardy recognition of the architect by the Press is but a bare act of justice long delayed, and in its inception naturally ill-expressed. Hitherto he has been consistently ignored. The painter who executes in pigments the creation of his brain, and the sculptor who puts in concrete form his fancies, are recognised as the authors of their creations, and are open to adulation or criticism according to the fad of the moment. Indeed, a Press warfare may rage around their work if the Press, that stern guardian of public morals, decrees so. An amazing amount of prurient rubbish is put in the minds of the reading public by these sticklers for purity, who do not hesitate to publish the nauseating details from the Divorce Court or the criminal courts. A notorious instance will be fresh in your minds, where the merits or demerits of the building were ignored, and the architect only came into prominence in connection with the decorative features which were the subject of the censure.

The painter and the sculptor who adorn the building, and whose work is enshrined in the architect's conception, come in for their full meed of recognition, while the obscure individual who provided a fitting home for such decorations, allotting with care and skill the right place and proportion to each, is ignored and buried under a deluge of statistics. The editors consider that the public are far more interested in the exact number of bricks used, or the precise quantity of cement employed, or the number of men engaged, and how many were killed or injured, and how many gallons of beer they drank. They hardly go far enough. Why do they not add the age of the contractor, a brief family history of the quantity surveyor, the weight of the clerk of works, and such interesting details? Why does it not occur to these editors to give the number of drawings made, the aggregate of hours spent upon them, and the quantity of pencils used? Why not detail the time occupied in party-wall disputes, struggles with innumerable authorities, and other engrossing matters? But hitherto no one has been interested either in the method by which a building is produced or in the man who produces it. But now that the public have discovered that a building does not rise spontaneously, and that there is a directing and controlling force known as the architect, there is a tendency to rush to the opposite extreme and advertise the architect at the expense of the architecture. This tendency has been aggravated by the result of the competition for the County Council Hall, where the picture of a young man, rising suddenly into prominence and fame, appealed strongly to the Press, and through it to the public. But what appealed more strongly still was the remuneration. You all saw it—in heavy leaded type—"A Fortune at Thirty-two!" Such minor points as that the receipts would spread over many years and be subject to heavy deductions for expenses were absolutely ignored. The impression conveyed was that the successful author had done his work, had received so many thousand pounds, and there his interest ceased. Not one of the papers, so far as I know, took pains to present the facts of the case, and how many presented a serious and authoritative criticism of the designs? Still, there is the salient fact that the architect has been discovered and has received a certain amount of recognition. How different from the time when the Imperial Institute was opened amid circumstances of unusual public interest and extreme pomp and ceremony. The papers were full of it, and devoted column after column to the event, but I cannot remember one which even hinted at the existence of an architect. Certainly, views of the building were published, but it is significant that the name of the author should be considered of insufficient interest to demand publication. There is no need to multiply instances. They will occur only too readily. But the prominent fact remains that only recently has it dawned upon Press writers that some man is responsible for a building which attracts public attention.

This is no plea for advertisement; it is hardly a plea for recognition. It is something more. It is a plea for the recognition of an art essential to the community, on the efficiency of which depends that community's well-being. It is an art which should appeal deeply to the artistic sense of the community (if it has any) just as surely as it should meet the demands of comfort and hygiene. The men who produce it should be subject to public recognition as benefactors. The painter and the sculptor receive that recognition to a limited degree as contributors to the artistic requirements of the nation. The engineer receives his meed of recognition as meeting the utilitarian demand. And these three rightly and yet inadequately. But the man who in his own person meets all three requirements after a prolonged period of obscurity, working beneath the surface, so to speak, producing art for art's sake, is just beginning to creep into the light of the Press, and is here and there receiving public recognition in the shape of well-deserved honours. In honouring them the profession as a whole has been honoured, and in honouring the profession our art has been honoured. This lack of recognition for benefits conferred upon the community—and again I must emphasise that point—has been due to a variety of causes. Partly the indifference and ignorance of the public, partly the lassitude of the profession, and partly the attitude of the Press.

It has been the custom of the Press to give undue prominence to law-suits in which architects have been involved, often to their undoing, and I have felt that the Press has taken almost a malevolent delight in holding up the unfortunate man to the jeers of the unsympathetic. For long years, whenever the architect has appeared in the pages of our journals, he has served as a butt for the shafts of somewhat clumsy ridicule. Occasionally I confess the ridicule has been deserved. More often it has not, and the daily Press, taking its cue from the pages of *Punch*, has continued a campaign of satire, which I submit has now become pointless and ill-deserved. I do not think as a profession we are more thin-skinned than other professions, or that we are free from foibles, and we do not claim immunity from the cheap sarcasm which passes for wit.

What we want, and what we do not get, is intelligent criticism from persons qualified to criticise. Here, I again submit, we have a genuine grievance against our otherwise excellent Press. If the editor of a newspaper requires a special criticism upon an exhibition of paintings, presumably he does not entrust it to the hands of a reporter whose speciality, we will say, may be writing a *précis* of Divorce Court proceedings. Not at all. The task is given to a man who is a reputed critic at any rate, though his criticisms may be, and too often are, valueless, and invite only the derision of the artist. Of course the public is no wiser, and meekly accepts the dictum of the great man. Again, does an editor depute the criticism of a new play to a reporter whose speciality is the sensational writing-up of murder cases? On the contrary, the task is entrusted to a recognised and frequently well-known dramatic critic. Now both these critics—the art and dramatic—are supposed to be well versed in their particular lines; the one, to know all about the old masters, colour, chiaroscuro, grouping, drawing, perspective, and the rest of it; the other, a sort of play-writer encyclopædia, ready to convict the unwary author of plagiarism at short notice, a judge of elocution, of stage-craft, and goodness knows what else. If the intelligent editor desires a special article upon an army matter, does he follow the example of our Governmental system and put it in the hands of a civilian? He surely goes to the man with the special knowledge—the army man himself. If a naval subject has to be written up, is a novelist the proper authority to deal with it? And yet, on the rare occasions when an architectural article is required, how often is an architect employed to write it? Not long ago I was staggered to see in a sober evening journal, and not one of the sensational journals either, this very unfamiliar heading:—"Architecture in the West End. By an Architect." And a very good and well-written article it was, to my mind. I make the editor my compliments. Too often, I fear, if a building has to be "written up," it is the custom to apply to the architect for a written description, and probably the fearsome "specification" English disclosed puts the average editor in wholesome terror of an architect's literary accomplishments. And yet I venture to think a perusal of our professional journals and proceedings will show that the architect can more than hold his own in the literary field.

For long years the profession has endured slight, calumny, misrepresentation and distortion in the Press, and endured it "lying down." Not that there has been no opportunity for retort. Within my recollection scarcely a newspaper article, description, criticism, or witticism, scarcely a magazine article, scarcely a story or novel, but has contained some glaring solecism or inaccuracy which has excited the derision of the architect. But then the reader does not know in his blessed ignorance, and the architect

Digitized by Google

has left him to wallow in it. Is there any other conceivable subject under the sun as to which a writer would take no trouble to verify his facts? Is there any other direction in which the reader or the critic would not pounce on inaccuracy and take care to correct it? Why, the correspondence columns of our newspapers thrive on this sort of thing. How is it that we never see corrections of architectural inaccuracies? Do we as a profession consider such things beneath contempt, or do editors reject such communications as "not being of sufficient public interest"? It would be interesting to know indeed. I do not want to bore you with examples which must be only too fresh in your minds, and one or two only must serve to illustrate my point. In a novel by an extremely well-known and popular living writer is a description of an invalid's bath-chair being wheeled down the steps of the house by means of planks laid from the lintel of the door to the ground. Having gone out of his way to indulge in detail, he perpetuates a gross technical absurdity by a confusion of terms which a little trouble would have obviated. Why, the translators of the authorised version of the Bible had a better technical knowledge, as those who remember their twelfth chapter of Genesis may know. But this is not the point. The distressing fact is that as far as I am aware not one critic seized upon the solecism. Was the author who wrote of the "stone gargoyles which grinned down upon the passers-by from each stone mullion" held up to public derision as a person with a little dangerous knowledge? Not at all. Was the lady who wove a novel round one of our English cathedrals, a novel full of gushing and fulsome anachronisms, pulled up for references to cloisters which simply do not exist? Never to my knowledge. Are any of the newspapers with their turgid descriptions of buildings ever pilloried for their wilful ignorance? Again, I ask, whose fault is it?

We architects bleat glibly of "educating the public," and yet we do not take the means readiest to hand for doing so. It is no use holding up these erring ones to the derision of architects in the professional Press. They should be taught through the columns of the general papers to take the same care with architectural technicalities that they would take with any others. Almost a worse type of offender is the one who has a nodding acquaintance with technical terms and showers them upon the long-suffering reader as proof positive of his superior knowledge—a blatant assertion of his real ignorance. I venture to think, however, that this state of things is passing away and the colossal ignorance hitherto shown will no longer be tolerated by a better educated public. I suggest that the Press is lagging behind and but slowly following the public demand, instead of exercising its true function in leading and developing.

It is not realised how intimately the daily life of the community is associated with the buildings in which it dwells, worships, conducts its business, works, amuses itself, houses its museums, its works of art, its learned societies, its law courts, its vast system of government. The very necessities of life are bound up in the edifices which meet the eye everywhere.

(To be concluded.)

IDEAS IN THINGS.

On Wednesday evening last Mr. C. F. A. Voysey delivered at Carpenters' Hall, London Wall, the first of his lectures on "Ideas in Things," in connection with design as applied to completed work. The age we live in, he said, is intensely material; it has witnessed a mighty development in things material. The steam engine and electricity have transformed the world; our minds have been engrossed by material ideas to such an extent that we have scarcely devoted that attention to the spiritual side of our natures which that side deserves. It is for us to kindle the thought and feeling that shall form the motive power by which material forces are to be turned to good account. It is lamentable when men's minds are so absorbed by material conditions that they lose all sensibility to the higher forms of usefulness and happiness. Materialism alone is a demon of unrighteousness; one of its commonest effects is to belittle the faculty of reason, and allow the will to follow the dictates of the emotions. We are content to be pleased with anything, without asking ourselves why. Things said to be charming are often accepted without question. Artists have been heard to openly affirm that art has nothing to do with reason They say they are led in a mysterious way in their work, and never reason about it, although they talk reasonably enough about material qualities. The presence of so much ugliness in life to-day is largely due to the materialistic habit of mind. We love ease far more than beauty, utility far more than inspiration, and consequently "ideas in things" are not readily recognised.

All art is the expression or manifestation of thought and feeling, therefore a technical knowledge of any craft by itself is but a language with which to express thought and feeling. And such qualities of mind as accuracy, order, neatness, precision, frankness, love of truth, and above all reverence, are some of the qualities we call spiritual, because they minister to our characters far more than to bodily comfort. We may make doors and windows, chairs and tables with mechanical exactness, and be paid in coin in exchange, but neither we nor those who pay for them will gain any spiritual benefit from our labour unless we have put our hearts and minds into the work, anxiously seeking to impart some good thought and healthy feeling. Whether or not the workman be seeking to gain praise for himself, or express praise of lovely qualities, will make all the difference to his influence through his productions. It will be vain and frivolous, or dignified, simple and restrained. A thousand subtle feelings may be suggested by it according to the earnestness and purity of the man. It is base materialism to shut our eyes to the spiritual character given by man to matter. Materialism has given rise to a thirst for artificial excitement. For in proportion to man's loss of interest in spiritual ideas, and in the manifestation of moral qualities, he loses enjoyment in his work, and cries out for amusement by itself. A workman to whom his work is a feast of reason and a flow of soul does not want to waste much time in watching football matches; he is not hungry for the excitement of gambling; his joy is more constant and less spasmodic. The old carpenters derived deeper pleasure from their work than we derive from ours, because they read less and thought more; putting more thought into their work, more thought was got out of it. Their ideas were fostered and stimulated by the thoughts and feelings in the things around them. The capital or doorknocker were eloquent in their appeal to their fancy. But now the idea that a chair or table can be made to express thought and feeling seems to the carpenter quite ridiculous. Once let it be recognised that the spiritual verities are of primary importance, and that we can help on our own as well as our neighbours' growth in virtue by trying to put thought and feeling into our work, we shall then find an added joy in labour far more precious than any material reward. Many of the schools teach that in certain past ages very beautiful work was done, and that such beauty is not possible to this dark age. We are all miserable sinners, so they say in effect; we must go on hands and knees and measure up, and draw and learn like parrots to imitate with technical excellence what the ancient and good have showed us. This is false teaching. There is as much capacity for goodness to-day as there ever was in any age. Men can turn out work as perfect in all material qualities as the world has yet seen.

The human quality in familiar objects has in many cases been driven out by the machine, and the lack of spirituality makes many content with mechanical things, and lose their taste for the subtlety and charm of human work. Nevertheless the machine has come to liberate man's mind for more intellectual work than was provided for him by the sawpit. Conscientiousness and a love of truth and hatred of all forms of deception will help us to make the hidden parts of our work as good as those that are seen. What carpenter would not enjoy making articles of furniture of one quality throughout instead of oak in front and deal behind? And patrons, if they too felt the same, would be glad to pay for the absence of sham. If we would frankly acknowledge the structural necessity of nailing down floor-boards, we should not strain our ingenuity in devising methods of secret nailing. The age is far too keen on mechanical perfection. The modern builder will have the arrises of his stones drafted and made mechanically square and true, so that the mason can set them with plumb-rule and little or no thought, preferring that mechanical exactness to the work of the painstaking human eye. And alas! many a mason prefers to use a tool rather than have to think. All have observed the soft yet massive effect in old buildings, when the angles were put up by human eye. Compare them with the hard, unsympathetic, mechanical effect of the modern drafted angles. It would be inadvisable, of course, to go back to all methods of hand labour and to neglect the aid of the machine. All we need is to recognise its material value and its spiritual imperfection, and put into all our hand work that thought and feeling which is the breath of life. All the beautiful human work that has been bequeathed by the ages was the outcome of sincere and honest thought and feeling. Let us

Digitized by Google

then see to it that our work is palpitating with sincere and noble thought, and feeling. The frame of mind of the joiner in mitreing his architraves is destined to have its effect, whether he be followed by the painter or not. Faithfulness in little things builds up the strong character and makes work enjoyable to the worker, and lays the foundation of that sense of beauty which all need. If work is to be fit and beautiful, it must express some good thought or healthy emotion. Whatever we make, be it only a chair, can record our honest endeavour to serve a useful purpose and stimulate kind feeling.

Students think to ease their labours with the polish of Greece and crumbs of knowledge from Italy. When asked to design anything, they immediately inquire how someone else did it; having no reverence for contemporaries they look to the dead and buried and find the museums crowded with lovely examples. Every inducement is held out to use the wits of others rather than their own. If we would go humbly to nature more, we should have a juster reverence for man's work. We should not be content to copy his successes and his failures, without exercising our own faculties. It is much more healthy for a student to be told the conditions and requirements necessary to provide any given object of use than to set him to copy the best example of the same in existence. The process of thought in the classification of requirements and conditions is immensely valuable. It stimulates the faculties and warms the heart and encourages the feeling that there is always room for improvement. But the general method of procedure is to fix on existing human productions as more or less perfect and final, and at any rate superior to our own, and then copy without having a full knowledge of all the circumstances and conditions that give rise to the object of our admiration. The student's faculties are in this way cramped and petrified.

It is quite easy to see when articles of daily use are made by loving hands and thoughtful heads, and when they are made by human drudges working for wage alone. To impart this human spirit to anything, we must not imitate blindly; no feeling can be imparted until it has been truly felt by the workmen.

One of the chief reasons why we should evolve our creations out of a due consideration of conditions and requirements instead of imitating tradition or well-beloved examples, is that our conditions and requirements are always changing; new methods and new materials are constantly being evolved, and men's habits and tastes are for ever developing.

Think what a keen love of cleanliness could do if applied to our architecture in dirty towns. How much so-called ornamental enrichment collects dirt and depresses us by harbouring all that is unclean and repulsive, producing feelings the very reverse of pleasure. The very proper pleasure we feel in dexterity is often sacrificed for the sake of elaborate ornamentation that is hopelessly meaningless and sometimes used to hide bad workmanship and bad material. This kind of enrichment gives no pleasure and cannot stimulate any nice feeling or healthy thought.

Often a feeling of generosity is expressed by making the parts of a building or object larger than may be actually required on structural grounds. For instance, the old roofs were composed of massive timbers, it being in old time often cheaper to use a whole tree than to cut it up. There is a certain satisfaction to the eye to be gained by proportions which are in excess of mathematical requirements. We call the architect's work an art, but the engineer's work a profession, and the difference may be traced to just that addition of the spiritual quality of generosity, just that thought and feeling which humanises the work.

In conclusion Mr. Voysey said a little more love of peace and quietness and a greater readiness to take a seat behind nature instead of crushing her under foot will help to make our buildings more pleasing and restful. Greater spirituality, in fact, shall blot out all material vulgarities. The wonderful resources for gaining knowledge and culture have not made our work more beautiful. The most intimate knowledge of the history of Greece and Rome, what has it done for our buildings? It has failed hideously and stimulated pride in scholarship. It has made us vain but not thoughtful, arrogant but not emotional. Better to have sought out the immortal thoughts and feelings that guided the spirits of ancient times. Materialism has been the seed so sown and we have only tares to reap. Or rather say we are at the end of a hideous night, and are now awaking to the necessity of sowing living seed. All around are signs of renewed spiritual activity and a reaction from materialism.

DEVON AND EXETER ARCHITECTURAL SOCIETY.

THE annual meeting of the Devon and Exeter Architectural Society (embracing the counties of Devon and Cornwall) was held at Plymouth, the President, Mr. James Crocker, F.R.I.B.A., of Exeter, being in the chair. The twenty-second annual report stated that the roll of members now stands at eighty-five. The Council still regret there has been no response from the younger members, whereby students of the society may join the school of design of the London Architectural Association. Therefore the guinea book prize offered by the society to the competitor whose design is placed first has not been awarded. It is also noted with regret that the attendances of members at the general meetings continue to be small; and that when papers are read, the benefit they are intended to supply is not gained. For the two guinea prize (in books) offered by the society for measured drawings for 1908, only one set was submitted; but, being deemed worthy, it was awarded to Mr. W. W. Hitchins, of Plymouth. The balance-sheet was of a satisfactory character and with the report was unanimously adopted.

The retiring president, Mr. James Crocker, then read his address. After some introductory remarks, in the course of which he expressed his belief that architects would soon see a return of the wave of prosperity, Mr. Crocker said in an address of this kind, however brief, some reference should perhaps be made to the present position of the profession, and of architecture generally; the former thought divides itself under one or two headings. It is true that the services of an architect are now almost invariably called in, or rather the work, whatever it may be, is carried out upon some sort of definite plan prepared by somebody; and this takes us at once to the subject of "The Architects' Registration Bill" or "Architectural Registration," which I have now advocated for many years.

Something more than merely "marking time" has taken place during the last decade, but the wheels of the coach run very slowly, and meanwhile there has been an addition to that ever expanding army of those who take on architecture with an audacious flippancy, and with no necessary qualifications beyond the ability to plan four square walls and cover them with a roof. I am not going to recount all the evils of the present system because you all know them, and have mostly made up your minds about them, but the extraordinary thing is the gullibility of the public. It vainly hopes for what it has no right to expect, and is disappointed because it does not get it; but if the architects of this country were to put into practice what an enormous majority of them are perfectly agreed upon, they might bring this measure off without delay. Notwithstanding the almost feverish anxiety which has been displayed within the past few years for the teaching of drawing in all its branches in our schools and colleges, and even the establishment of chairs of architecture, it amounts almost to a national reproach that in the particular way to which I am referring, architecture is found in the condition in which it now is, and allowed to "limp along" on its own.

I feel strongly that this official indifference is one of the gravest things we have to think of. Those of us who have to look back over more years than we can possibly look forward to will have little to gain by the passing of this Bill, but we shall, by using every legitimate effort, be doing what every corporate body is bound to do, viz., that which is for the best interests of those whom we mutually serve.

There is another subject which is constantly being pressed upon us, and that is the overcrowded state of the profession. It is a condition not singular to the profession of the architect, but it is none the less serious, and the remedy if there be one ought to be discovered. This state of things exists from two or three causes; one is that of which I have been complaining, and which the Registration Bill through closing the open door would partially cure. Another is the great facilities granted for learning drawing and architecture in the various schools and colleges, creating draughtsmen by machinery; and a third evil is to be attributed to the natural but oftentimes disastrous ambition on the part of parents to make their boys what they were never destined for. A large number of boys enter the ranks of architecture who would be much better in a trade or business, for they only get intermittent employment, and when it is too late to find out that their choice has been a mistake. This serious state of things was referred to at some length by the President of the Architectural Association in his address in October last, in which he stated that some members had sent in their resignation through inability to meet their subscriptions.

Digitized by Google

I should like also to make a suggestion or two, more especially to the younger members, on the subject of sketching and tradition. As to the former, I have for years constantly expressed a fear that there is a great risk of its being neglected in favour of the camera; and let mé say the one can never take the place of the other without serious loss to the student. My thought on the second subject is a plea for the carrying on of the traditions of a county or a district both in the matter of materials and treatment. This is a sound principle to work upon, and although Devon and Cornwall are not so rich as some others in examples, we need proceed in no uncertainty. We cannot take a walk or a short journey without noting the incongruities arising from a transgression of this principle.

And now to make a few observations upon the position of architecture as we find it. In doing so one is met with the initial difficulty that it requires the perspective of years to fairly judge of the past, and that we have to hand on our works to those who come after us without final answer, and with the note of interrogation still standing. This is only expressing a platitude, but nevertheless he who runs may read, and it is impossible to look upon the brilliant work of the past fifteen or twenty years without feeling that we are living in a great age, and probably making a history according to its kind, almost if not quite equal to that handed down through the middle ages, and by the influence of Inigo Jones and Wren. But what a revolution has taken place within the last sixty or seventy years! The Gothic had spent itself, as it has now done again, and the later Renaissance, in the midst of great wealth, had reached a period of decadence which found its worst expression in the hideous country mansion. Ecclesiastical restoration was invariably ecclesiastical desecration, and early Nonconformist architecture, in its struggles for existence in any form, has been aptly described as "the barnic order," with the inside like a sawpit, and galleries all round.

We live in times of greater inspiration; times in which the public taste is alert to the things that are best, and if not always technically safe is mostly easily guided; times of great public and private ambition in which there is some joy in living, and in which we have some opportunities here and there of not merely working for a living, but leaving a memorial; and if in the fulfilment of this object we constantly look back and live in the company of those who have gone before us, maintaining the traditions they have handed down, and gathering up all that is best in their works, and welding them with our own ideals, we shall by so doing best realise that which is the highest object of the artist—not the mere making of money, although I hold no Quixotic notions about that; nor the winning of popularity if it is to reach us through the avenues of vulgarism; but the enhancement of the art we have espoused.

The following members constitute the officers and council for the ensuing year, viz.:—Mr. W. H. May, M.S.A. (Plymouth), president; Mr. Charles Cole, M.S.A. (Exeter), vice-president; Messrs. M. Alfon Bazeley (Plymouth), James Crocker, F.R.I.B.A., John M. Pinn, T. A. Andrews, J. A. Lucas, A.R.I.B.A., O. Ralling (Exeter), C. Cheverton, M.S.A. (Devonport), J. C. Southcombe (Barnstaple), Mr. S. Dobell, hon. treasurer (Exeter), and Allan J. Pinn, A.R.I.B.A., hon. secretary (Exeter).

ANOMALIES IN BY-LAWS AND REGULATIONS WHICH AFFECT SANITATION.*

(*Continued from page* 118.)

IT is not my intention to enter into the much debated question of *iron versus* earthenware for domestic fouled water drains, beyond that my own experience is entirely in favour of iron.

There are considerable variations in the practice of providing foundations for drains, as also in the thickness and peculiarity of form, but the omission of these from the by-laws of many districts where earthenware or even stoneware pipes are used is wrong, as with pipes of this material no ground is free from the probability of movement that will either disturb the joint or break the pipe.

In regard to depth of drain or inclination of fall, little attention is paid, except that there is no limit to the depth they are buried, providing there is fall to the outlet and the fall steep enough, the latter not always a desirable condition, especially in a drain too large for its work.

In most provincial towns the work of laying domestic drains is done by the excavator, or, as his bill of quantities describes him, excavator and drainer, a practice which should be universally condemned for the reason that there ought to be no divided responsibility in this part of the work between the plumber or technically-trained man and what is often an unskilled labourer.

It is quite obvious that as great, if not greater, necessity exists that drains which are out of sight and may create irreparable damage before the cause is apparent should require a knowledge and expert training equal to that of drains above ground, when defects are more easily apparent and have the additional advantages of free circulation of air and sunlight to counteract the effects of their leakage.

In the matter of testing drains the same inconsistency of practice obtains, although the method is not so often defined by the by-laws, but rather depends upon the selection of the official for whose information the test is made.

Most authorities are content with a smoke test either before or after the drain is covered; some insist on the test being applied in both conditions. It is, however, quite obvious that this method of testing is very unreliable after the earth is replaced in the trench, and a drain that may have answered to this test when exposed and which is disturbed in the process of filling in and consolidating the earth may easily be defective without the possibility of discovery by the smoke test when applied afterwards.

It would appear much more reasonable to submit the drains to a test of the elements they are intended to convey and made with air and water under a pressure slightly greater than they would normally be required to withstand. In some districts junctions and bends are permitted, and but a few (unfortunately) insist upon inspection chambers at all junctions and bends with air-tight covers. In these latter and favoured districts there is, however, little attention paid to the designing of a general scheme for the domestic drains which will limit to the minimum of necessity these inspection openings.

It is again unnecessary to point out that no variation of local conditions can require such a numerous variety in either material or practice in so simple a matter as domestic drains; the object sought cannot be equally well secured by all these methods, or, if so, some of them are unnecessarily costly.

The elementary principles taught, and which govern this particular work, require that a drain shall be laid to regular falls on straight lines and accessible from point to point, for the purpose of periodical cleansing or removing of any obstruction which may occur; and it is further admitted that no ground is absolutely free under all conditions from the movement or shrinkage which is liable to injuriously affect the rigid joint or material of a drain not strong enough to resist such conditions, causing consequent leakage not easy of detection, with potentialities of danger and discomfort. The drain and its joints should therefore be strong enough to resist all adjacent movement or be laid on a foundation which will secure a like result.

Of gullies and traps there are an infinite selection of shapes and sizes, not a few of which are distinguished by the name of the town or district, whilst others stand as a permanent record of some fad or fancy of the official or sanitary expert who conceived their peculiar necessity of form; but few are designed to secure the most efficient results in their use, and in these are by no means included the examples of misdirected ingenuity for which the sanitary official or expert was responsible.

There is also an absence of regulations which limit the number of these intended safeguards, thus ignoring the principle that one trap may effect its purpose, but that a multiplication of traps may provide a number of dangers greater than the one they are intended to minimise, not least of which are the impediment they provide to the flow and force of the irrigant upon which depends the progression of the solids or flocculent matter to the point of discharge into the sewer and the decomposing sediment they retain owing to defects in their form and capacity.

In these appliances occur the same wide divergencies of approval or rejection by different authorities.

Some will be found to insist upon the provision of a huge 6-inch gully, with a capacity of some four gallons or more, to receive the discharge from a bay-window pipe of 1½-inch diameter that may discharge at most a gallon of water during the period of an occasionally severe rain storm, the doubtful advantage being that it does not often completely stop for want of cleaning out and does not soon lose its water (or more likely mud) seal by evaporation. In all gullies at present used there are several defects, one of the

* A paper by Mr. William Challoner, president of the Institution of Plumbers, read before the Midland Association of Local Government Officials on February 8.

Digitized by Google

most usual being the form of the outgo spigot, which precludes the possibility of a tight joint, except by accident or the use of an unnecessary bend in the drain.

The common practice of fixing the gully "square off" the building and inserting a bend to regain the direction of the drain cannot be too strongly condemned.

The provision of guards to prevent the gully from receiving any undesirable substance are usually of a most unstable character, as is also the convenience for a necessary periodical cleaning.

The general trend of regulations which affect underground domestic drains, through a disregard of common-sense principles (such as suggested when dealing with earthenware drains), tend to create elements of danger, and in the guily or trap is provided a belated expedient to safeguard these often unnecessary conditions, but instead of doing so these in their turn provide a greater certainty of danger than the one they are intended to counteract.

Almost every district in its own peculiar way imposes some regulation which illustrates this tendency to provide a series of lines of defence against possible dangers which can only arise through defective construction in the drainage system itself, and which permits the retention of originally innocuous matter until it becomes disagreeable, if not dangerous, by the process of putrefaction.

One illustration of this is provided by the 18-inch long open channel from all sink pipes to the gully, which is insisted upon by most of the authorities within the metropolitan area and by some in the provinces.

Whilst it would appear that the original purpose of this expedient was to cool any hot water before it should enter the drain, for which purpose it was both unnecessary and useless, its main purpose at present is alleged to be a means of disconnection to prevent the possibility of bad air entering into the house up the sink pipe.

It may be of interest to consider how far the defects for which this safeguard is the intended antidote are preventable and in what degree the disconnecting channel contributes to its own necessity.

The absence or provision of this channel cannot affect the usually filthy 1½-inch lead sink pipe and its trap under the sink, which will neither gain nor lose effluvia by this precaution, but it will so disperse the slight force of the discharge from the waste pipe as to render it useless to disturb the contents of the enormous gully, on to the grating of which it eventually delivers it.

After being further dispersed over the grating it trickles down the sides of the rough brick eye, which bungs up the earthenware grating or clumsy dishstone to the level of the yard or area.

There is usually a waterway of about 1 inch beneath the dip of the gully, just kept clear by the trickling of the water in manner as described. The rest of the inside of the gully is a miniature anerobic tank, seldom cleaned out except when some case of zymotic disease has occurred and the drain-testers come along or the drains are up for repairs.

We may safely anticipate that the 4-inch drain from the sink gully to the outgo is more or less fouled with putrefactive matter at every joint and over two-thirds its internal area, and that the air in the same space is never displaced until the gases generated are in sufficient volume to force themselves out at the only open end, which is at the lowest point and quite opposed to their natural direction. It is apparent that this multiplication of defective conditions could be easily prevented, and that they are aggravated to some extent by the provision of this channel.

The whole arrangement is a double or treble precaution to deal with an easily preventable contingency. This is a typical illustration of how in this work provision is made for contingencies that seldom occur and which at other times provides a source of danger greater than the nuisance it is designed to prevent, and that, given common-sense principles in the construction and design of the work, the result would be the simplicity of action and economy on area upon which the safe reception and conveyance of putrefactive matter depends. *(To be concluded.)*

Mr. W. Birnie Rhind, sculptor, recently wrote to the streets and buildings committee of Edinburgh Town Council asking permission to erect the proposed Black Watch Memorial in the centre of the Princes Street end of Castle Street, but the committee delayed the matter in order to have before them a sketch. It had been previously decided to erect the memorial on ground belonging to the Bank of Scotland at the Mound, but it is understood that so many restrictions were imposed that it was decided to abandon that site.

Correspondence

Steelwork.

SIR,—I appear to have aroused the lion of the reinforced concrete camp, and what is more he is attacking me with tooth and talon for daring to utter a note of warning in regard to the use, or rather abuse, of this form of construction. I may say this is not the first time I have endeavoured to point out the danger of employing this combination of material under certain conditions; some time ago I sent a similar article to a journal that discourses freely on ferro-concrete work, but apparently this kind of communication was not wanted.

Here let me assure Mr. Twelvetrees that I am dealing with this matter purely and solely from the standpoint of a consulting engineer; my remarks about commercialism I will postpone until the end, so that your readers may omit that portion if they feel so inclined.

Mr. Twelvetrees would, however, do well to remember that it is generally the counsel that has a poor brief who tries to discredit the standing of a witness. Now to the point in question, which is whether reinforced concrete is a safe form of construction for beams, where they are exposed to moisture or other corrosive agents.

Unfortunately for simplicity's sake, Mr. Twelvetrees has expressed his calculations in the ratio of elongation to length; this naturally involves a long string of decimal figures. He, however, admits that the limit I stated, to which concrete would stretch under tension, may be taken at 1/10,000th of its length; that is to say, for a 2-foot length (I ask pardon for my temporarily returning to this length, assumed for the sake of making the figures less intricate) the elongation would amount to 24/10,000ths of an inch, or approximately 1/400th of an inch; this is quite near enough, considering the wide variations in the quality of concrete, and it has the advantage of stating the amount in round figures. When the concrete has stretched under tension 1/400th of an inch, it cannot stretch any farther, but must crack. Whether it still retains its additional length is doubtful, the probability is that it returns almost to its original length of 2 feet; otherwise how can the fact be accounted for, that a tested reinforced concrete beam will return practically to its original position after deflection? I wish to make this point clear, as Mr. Twelvetrees deducts the elongation of the concrete from that of the steel in order to determine the widths of the cracks; personally I think this is wrong, but it does not affect my argument to any vast extent.

Now as regards the elongation of a steel bar, subjected to a tensile stress of 7 tons per square inch, my figures and those of Mr. Twelvetrees do not vary very much. The elongation is inversely proportional to the modulus of elasticity of the steel; for my calculations I assumed the ordinary value of 12,000 tons per square inch (vide Messrs. Dorman, Long & Co.'s handbook); this gives an elongation of 1/1,700th of its length. Mr. Twelvetrees puts it at 1/1,900th of its length, based on the assumption of a modulus of elasticity of 30,000,000 lb., or 13,393 tons per square inch. Accepting his figures for a 2-foot length of a steel bar, the elongation would amount to 1/80th of an inch.

Again accepting his statement that the concrete retains its elongation after cracking, the difference in elongation between the steel and the concrete is 1/80th − 1/400th = 1/100th of an inch, as against my former statement of 1/70th of an inch. In any case, the total width of the cracks in a 2-foot length of a reinforced concrete beam, when the steel is stressed at 7 tons per square inch, would aggregate between 1/70th and 1/100th of an inch. If the steel is stressed up to 10 tons per square inch, the widths of the cracks would aggregate between 1/49th and 1/70th of an inch.

Now as regards the assumption of a 2-foot length Mr. Twelvetrees sarcastically remarks, "Mr. Childs probably knows, but omits to say, that the maximum tensile stress due to bending moment obtains only at the middle of the beam and progressively diminishes towards the ends, where the value is zero." I certainly omitted to say so, because the veriest tyro in constructional design knows that this is not true in many cases; as for example a beam carrying two concentrated loads of equal amounts, placed equally distant from the ends, such as a main girder carrying bearer girders. Here the maximum stress may extend over many feet; for

Digitized by Google

a supposed case, it may be taken at 15 feet, then the total width of the cracks would amount to, at the least computation, 1/13th of an inch. Perhaps Mr. Twelvetrees' mind is obsessed by the beam that carries an equally distributed load; for such a beam of 20 feet span, the minimum stress in a central 2-foot length would be 6.93 tons, if the stress at the centre were 7 tons; so that the mean stress is 6.965 tons. Surely this is near enough to 7 tons for the sake of demonstration.

When once a hair crack has started in the concrete, which as previously shown would occur when the steel is stressed at about 1 1/5 tons per square inch, additional stress would naturally tend to widen that same crack, this being the line of least resistance; the only thing that opposes this is the grip of the concrete on the steel bar; if this is sufficient to prevent the first crack from widening, then only will other cracks open in preference. I can assure Mr. Twelvetrees that "no unhappy contretemps" has led me to these conclusions, but I must say that my experience in tests is that cracks do become visible, and that too without the aid of a microscope.

Turning from the abstract to a concrete example, such as the Post Office buildings in Newgate Street, the practice in such cases is to form the bases of the stanchions of a comparatively shallow slab of reinforced concrete, the reinforcements being within a few inches of the ground, these slabs being subjected to a considerable bending moment. Presuming that the steel is calculated on a basis of 7 tons stress, and that only the minute hair cracks, as admitted by Mr. Twelvetrees, exist, is it not possible that these may so expose the steel bars as to endanger their corrosion from the moisture arising from the ground?

The result may happen that in the course of time the stanchions may take their bearing on the ground over an area more nearly approaching that of their shafts than of their bases. At any rate is it wise to trust the entire safety of an important building to the hope that such a state of affairs will not happen?

Why should concrete in itself when reinforced become more ductile than when in its plain state? Can Mr. Twelvetrees mention any other material whose properties are altered by its physical, and not chemical, combination with another material?

The early theories of Considère, Hatt and others, who claimed that concrete would stretch without cracking ten times more when reinforced than as plain concrete, are now generally admitted to be as much in error as their theory in regard to the tensional stresses to be allowed in the concrete for reinforced beams.

In an article by Professor Hatt, after he had commented on and accepted M. Considère's elastic theory, he goes on to state:—

"The point to notice is that we can count on very large deformations in the material of the *tension* flange. The stress in the steel reinforcing material may be near its elastic limit and yet the concrete in *tension* may still be carrying load without cracking. This element of strength may then be included in the analysis." (Re strength of beams.)

Professor Hatt would probably repudiate both these claims at the present time; certainly all building regulations state that concrete shall be considered as incapable of resisting any tension.

Passing on to Mr. Twelvetrees' statement that "The presence of an alkaline compound will prevent the process of rusting," he here states as a fact what is only a theory; a very plausible one it is true; some theory had to be devised to account for what I admit is a fact, viz., that steel as long as it is not stressed and is thoroughly embedded in the concrete remains rust proof. He has, however, stated the theory in such a way that it becomes misleading. The alkalis of course neutralise acids, whose presence, by the way, is not absolutely necessary for the formation of oxide of iron or rust.

In the formation of an alkali, which takes place during the making of concrete, as soon as the water is added its alkaline properties are neutralised by the radicals, with which it immediately combines; so that before the concrete is brought in contact with the steel, it is almost a certainty that these alkaline compounds are fixed and stable, and no further free action can take place amongst the alkaloids; this is a certainty, after the concrete has set. These alkaline compounds, one of which is water glass, exist too in very minute amounts capable of neutralising a very small amount of acid; probably all are more brittle than the concrete. What is more, the better the cement, the less amount of alkaline compounds it contains, and these have been accused of being responsible for the minute hair cracks that appear in perfectly plain concrete.

Mr. Twelvetrees' statement would lead a casual reader to believe that free alkalis exist in concrete after it has set, ready at any time to attack any acid that may be assisting in the "process of rusting." After the concrete has set the alkaline compounds can only prevent rusting, not by any chemical action, but by providing a minute protective coating to the steel, which is in all probability less ductile than the main body of the concrete.

Even steelwork in exposed positions receives different treatment from that used in buildings; it is of the utmost importance that all its members should be open to inspection whenever desired; it is not safe to trust to theories that all is well, and the same should certainly apply to reinforced concrete work.

A word in self-defence. I will confess my sins. I am somewhat interested in a reinforced concrete firm, one of the very few that can claim to be English. I am even a shareholder in two others; but if I were dependent on these alone I should take a great personal interest in the proposed Poor Law Reform.

For the last ten years I have been consulting engineer to reinforced concrete firms; had I not been so I should have been entirely dependent for my knowledge on the makers of books, and my practical experience would have been nil. My experience is (I hope Mr. Twelvetrees' is otherwise) that clients or architects, I know of no exception, go direct to the commercial firms, not only for the material, but for the design itself. If they would confine themselves to one firm, they would get a fine design and the firm a fine price, but to put work which includes the design out to competition puts a premium on scamped work. I may say that of late I have used what influence I have had with the firms for whom I have acted as consulting engineer, to restrain them from using reinforced concrete in such classes of work mentioned above, because I conscientiously believe it is to their interest, and to that of reinforced concrete work generally, to abstain from anything that involves an element of risk.

Finally I might ask Mr. Twelvetrees why it is that, if what he states is such a foregone conclusion, the Concrete Institute is circularising its members, asking them to give their experience in regard to the corrosion of steel in reinforced concrete work?

Your space, Mr. Editor, is of more value than a long apology.

C. V. Childs

Suffolk House, E.C.

Fire Risks in Public Buildings.

Sir,—With reference to your article in *The Architect* of February 12, the arrangements in Westminster Abbey are antiquated and deficient. The water supply for the hydrants in the triforium comes from a tank in the south-west tower, which has to be kept filled by a manual pump worked by, say, a dozen men, and, with the relief, eighteen would be required.

Suppose a fire was to take place in the night, there is probably not more than an hour's supply in the tank, and how the men are to be quickly assembled at a short notice is problematical.

I pointed this out to the assistant architect last autumn when I was making my inspection of the lightning-conductors, and asked to be allowed to embody the subject in my report, but was told "that the fire department of the London County Council are responsible"; but they certainly cannot throw a jet from the street level.—Yours faithfully,

Killingworth Hedges, M.I.C.E.,
Hon. Sec. Lightning Research Committee.

10 Cranley Place, S.W.: February 21, 1909.

Architectural Drawings intended for exhibition at the Royal Academy must be delivered unpacked at Burlington Gardens entrance on Friday, March 26; oil-paintings on March 27 and 29; sculpture on March 30. No artist is allowed to send or exhibit more than three different works.

The Wexford County Council have decided that the county should be divided into two portions, and to appoint two surveyors, at a salary of 400*l.* a year each, this sum to cover allowance for travelling and clerical assistance. The County Council offered Mr. Henry Webster, M.Inst.C.E., the county surveyor, the county surveyorship of half the county at a salary of 400*l.* per annum. This he at once refused, and handed in his resignation.

The Architect.

THE WEEK.

THE latest point relating to competitions taken up by Mr. K. GAMMELL is of considerable importance. It is of little use for the Council of the Royal Institute to boycott a competition whose conditions are unfair or undesirable, unless the members of the Institute loyally support their representatives. The class of promoters whose particulars and conditions need correction, though sometimes erring by ignorance rather than by intent, are most often just the people who will not swerve from their own course except under the persuasion of the mailed fist or the big stick. The mild remonstrance of the Institute will by them be treated with contumely and ordered to lie on the table, but the intimation of a taboo universally respected by the members will often bring the recalcitrants to a more reasonable frame of mind. The Council, however, can scarcely expect ready compliance with their decision when they are so exceedingly slow in making announcement that a certain competition is under their ban. It is no uncommon thing for members of the Institute to receive the first intimation of the Council's disapproval of the conditions of a competition when half the time allowed for the preparation of drawings has elapsed. When architects have not only planked down their one or two guineas for particulars, but have spent much time, thought, and expense on a well-advanced design, they want to have a run for their money, and to ask them to throw away all chance of recoupment is to put too great a strain on their loyalty. It is a comparatively small matter personally to the big-wigs at Conduit Street whether a particular competition is barred or not; but to the small fry, who are hoping by the ladder of competitions to mount to the seats of the mighty, it is of vital importance, and these are the men who make up the bulk of participants in all competitions and who can least afford to throw anything away, even the return of the sum they have paid for particulars.

WE are glad to note that in the House of Commons on Monday last Mr. W. REDMOND, rather dramatically, perhaps, furnished the First Lord of the Admiralty with the name of an Irish quarry owner who would undertake to supply the Admiralty with stone for the works at Rosyth of as good a quality and as cheaply as Norwegian granite is obtained. Norwegian granite, by reason of its usually excellent quality, its pleasant appearance, and its cheapness, has hit our home quarry owners very hard, but we have long felt that if the Irish stone industry, not only in granite but in marble and other building stones, were properly developed, there would be little need to go abroad either on the score of excellence of material or of cost.

THE report has been issued of the Departmental Committee on Humidity and Ventilation in Cotton-weaving Sheds appointed by Mr. HERBERT GLADSTONE in November 1907. For fine cotton-weaving it is essential, as in the fine lace-making industry of Belgium, that the atmosphere be kept moist; and one reason why Lancashire is the home of the English cotton industry is that its climate is naturally humid; but the Committee's opinion that it has been clearly proved that work in moist atmospheres at high temperatures is really and seriously uncomfortable for the workers, and probably, in the long run, injurious to their health. It scarcely needed a Departmental Committee to find this out. One would hardly select the atmosphere of a Russian bath as a pleasant and healthy condition for prolonged work. The Committee seem to be astonished that in dry sheds natural ventilation is considered sufficient, and that where such ventilation is in use the atmosphere, especially in winter, does not show worse results than they found. Even in the few instances when plenum and exhaust fans are installed, they are seldom used in winter. As most of our hospital wards have natural ventilation only—and this is preferred by the majority of their medical officers—it is clear that it does not necessarily follow that the atmosphere of a weaving-shed must be unhealthy because it has no mechanical ventilation. The Committee, however, is of opinion that regulations are required enforcing that arrangements shall be made that no person employed shall be exposed to a direct draught, and that the incoming air shall be sufficiently warmed to make the workers comfortable and prevent them from catching cold.

THE universal acceptance of the lowest tender is a practice far from capable of being always defensible. The possibility is ever present of a low price being offered by a cut-and-run contractor of doubtful stability or even an impending bankrupt, who, in desperation, is prepared to take his chance of a smash if he cannot by means of scamping or extras screw a profit out of the most unlikely contract. The result in such a case is misery to the architect and dissatisfaction or even loss to the employer, for if the latter signs a contract apparently giving him something for less than it is worth he usually gets less value than he pays for. Nothing for nothing and very little for sixpence holds good in building as in other mercantile affairs. The employer who wants a "bargain" in bricks and mortar generally gets a bad one. Various suggestions have been made to overcome the inherent weakness of competitive tendering. The selection of a limited list of contractors has long been in vogue, and, given the possibility of wise selection, has usually led to satisfactory results. There have been cases where a limited number of contractors have arranged who of them should be lowest, with a douceur to the others, but the occasions have been rare. A suggestion has been lately made that the lowest tender but one should be that for acceptance, so that no contractor would be tempted to cut his price too fine; but this method is obviously open to the chance of collusion, and needs only two scamps to form a confederacy. A far better suggestion in modification of this is that the tender to be accepted should be that nearest the average of the lowest half-dozen, or of the lowest half or even of the whole. We should not support the suggestion that the average of the whole list should be taken, as it nearly always happens that there are some tenderers who do not want the job, and purposely put their price high enough to escape getting it. But the average of a reasonable number of the lower prices will sometimes be nearer to a fair price than the absolute lowest. Not always, for, if so, it would follow necessarily that the lowest price is invariably too low to allow a contractor to give good workmanship and materials to the employer with a fair profit to himself. On the contrary, it not infrequently occurs that the lowest tenderer is able, quite honestly, to make a larger profit than some of his competitors would have done had their higher prices been accepted. Those who have had the opportunity of analysing competitive prices know that the lowest tender is very often such by reason not of a generally lower scale, but of some particular section of the work as to which the lowest tenderer is in a peculiarly fortunate position.

RECENT discoveries at Sparta have considerably increased our knowledge of Greek history and life. From a number of inscriptions of the second century—to be precise, dating between A.D. 170 and 190—it seems clear that at this period of the Roman domination, with its tendency to luxury and enervation, there was a recrudescence of the old Spartan spirit, an effort to revive the simplicity and austerity of which LYCURGUS was the traditional founder. It appears that during this time "the divine LYCURGUS" was at least eleven times elected Patronomos of Sparta—an office corresponding to that of Archon at Athens. Nor was this office a mere sinecure, for the deified LYCURGUS, being unable to take an active part in the government of the city, a deputy was appointed to maintain the observance of the old-time customs and traditions of the Lycurgean era, including the peculiar ritual associated with the cult of ARTEMIS ORTHIA. This is the only instance at present known of a deified legendary hero with an acting deputy occupying the position of magistrate on the mainland of Greece, although it was not at all an uncommon arrangement in Asia Minor.

FRESCO PAINTING.*

FRESCO painting is in this country rather under a cloud at present, principally, if not entirely, no doubt, from the failures of mid-Victorian essays in this department of art work. The most important of these failures and the most influential in their deterrent effect upon its further employment are without doubt the examples in the Houses of Parliament. This failure has been ascribed to the dampness of our climate and the argument advanced that under such climatic condition fresco is necessarily incapable of durability and entirely unsuited for our country. The more truthful explanation is that the mid-Victorian artists did not sufficiently understand the limitations, physical and chemical, of true or buon-fresco and the necessity for a properly prepared wall surface and limited palette of colours. It is well, therefore, that we should have, in the volume now before us, the essential conditions for permanency in fresco painting clearly and succinctly laid down by an expert.

It is idle to gainsay the permanency of fresco painting in view of the examples recently discovered at Tiryns, at Thera and at Cnossus, none of which can possibly be of later date than 1500 B.C., whilst some may be as early as the nineteenth century B.C. Mr. Ward gives in his book an illustration of a fragment of ancient fresco from Tiryns.

We should note that there are several methods of applying colour decoration to plastered wall surfaces that have been loosely described as fresco painting; true or buon-fresco, spirit fresco, encaustic, fresco-secco, water glass, tempera and a combination of buon-fresco and tempera. With the possible exception of spirit fresco, whose introduction has been of too recent date to allow of full comparison, none of these can hold a place in durability with buon-fresco properly carried out.

Buon-fresco may also be rightly regarded as the most architectonic of all methods of colour decoration or painting, both because the colour becomes physically as much part of the building as stone, brick and plaster, and because the limitations of technique impose a restraint upon the painter, both in colours and in handling, that ensure his work being decorative rather than pictorial, so that it appears, as it should be, part of the wall and not a window through which an extraneous view is to be seen.

Though fresco has in the past been mainly concerned with subject-painting, so that we associate it with the idea of a more or less conventionalised picture, there is no reason why the methods of buon-fresco should not be utilised for pure ornament within the scope of an ordinary journeyman decorator down to the simplest arrangement of line or pattern with far greater permanency than that of oil-paint on Keene's cement, or any other medium at present commonly in use. The public is not prepared at all times to pay for the services of a great artist to decorate the walls of a building; it cannot afford always to employ a Leighton, a Poynter or a Richmond, but it is, so far as our experience goes, ready to accept colour decoration, even if it be only stencilling. It would be possible to use stencilling in buon-fresco, but the process is not the most suitable and is by no means necessary on the score of economy. It is one of the advantages of fresco that it is applicable to any surface whatever that can be plastered, and the methods of buon-fresco followed by the greatest artist in the most elevated work can equally be adopted by a journeyman decorator in the rendering of the simplest and most conventionalised ornament. It is not requisite that the architect should provide panels in which the fresco painting shall be, as it were, framed. The entire wall may be covered with fresco, partly pictorial to any extent that funds will permit, and partly decorative ornament, unity of effect ensuing that makes—given, of course, artistic skill and judgment—an architectural character to the whole scheme of decoration. The adoption of the methods of buon-fresco by architects would familiarise the public with its advantages and lead to the further and more general employment of pictorial artists for the purposes of wall decoration.

Where buon-fresco is to be applied, the first duty of the architect is to provide a dry wall, and Mr. Ward recommends that this should be of good brick, or if of stone, that it should be lined with brick, or, better still, a hollow brick wall. To this we would add that the architect should not attempt to ensure dryness by the use of Portland cement. Our modern Portland cement has in it so much of sulphur compounds and is so greatly given to effloresce that its use would be fatal to the durability of fresco. The joints being properly raked out for a sufficient key, the first coat of plaster may be applied, and this Mr. Ward advises should consist of "old lime" and coarse, gritty, well-washed river sand, mixed with ox-hair or white asbestos cut into small bits, the proportions being one of lime to two of sand and the coating about three-quarters of an inch in thickness. By "old lime" we opine that the author means lime that has been long slaked under water in the manner adopted for centuries by the Italian stuccatori and by the use of which they produce not only in their own country, but elsewhere on the Continent, and particularly in Austria, stucco that, used externally, is as lasting as the majority of building stones and more so than many. It is the universal custom of the Italians to keep the lime for at least twelve months under water so that it becomes completely hydrated, but not at all carbonated. Air slaked or carbonated dry "old lime" would be useless. The first or pricking-up coat of plaster, roughened to form a key, should be left for the best part of a year to harden, and is then ready for the final coat or intonaco, to which the painting is applied. The technique of this coat is quite simple, but strict adherence to details is essential, and these are clearly explained by the author.

In the actual painting the most important consideration is quickness, so that the colour may be all laid on before the plaster dries. The painter must therefore completely make up his mind before the plasterer starts on the intonaco what he is going to do, and must do it. There is no time for experiment and very little for touching up or amendment. Hence a finished coloured drawing of the design and a full-size cartoon are imperative. It is the provision of this full-size cartoon that renders the methods of buon-fresco applicable, as we have pointed out, to decoration by means of conventionalised ornament. From the cartoon the drawing is transferred to the wet plaster by pouncing or tracing, and a journeyman decorator of quite ordinary capacity could do this and apply the colour. The palette of colour is limited in range, but sufficient for a fairly rich and luminous colour scheme, and Mr. Ward gives a complete list of the pigments whose permanency may safely be relied upon, as well as an account of those of a more dubious character.

With a strict observance of the very simple methods of buon-fresco, its absolute permanence is certain as long as the plaster lasts; but if this is attacked by damp or sulphurous gases, its destruction entails that of the fresco painting chemically incorporated with it.

Spirit fresco as invented by Mr. Gambier Parry does not possess that peculiar quality of monumental dignity nor the undoubted luminosity characteristic of buon-fresco, but, as far as experience goes, appears equally permanent. The basis of the process is the employment of a solution of wax and gum elemi in copal varnish and volatile oil of spike, and it has the advantage of permitting over-painting and retouching at any interval of time after the original work. It is thus more in accord with the usual practice of painting in oil, and hence, no doubt, appeals more powerfully to the pictorial artist, but, to our mind, is, by reason of the latitude it affords, far less likely than buon-fresco to produce wall decoration that is part of the architecture of the building. Paintings in spirit fresco may be and are executed on canvas in a studio and then stuck on to the walls of a building as in the case of some of the pictures in the Royal Exchange, so that except as a curiosity it is hardly worth while to paint in the medium on plaster in situ, and the resulting decoration is no more part of the building than an ordinary oil-painting on canvas. Mr. Ward gives a full account

* *Fresco Painting: Its Art and Technique, with Special Reference to the Buono and Spirit Fresco Methods.* By James Ward. (London: Chapman & Hall. 1909 10*s.* 6*d.* net.)

Digitized by Google

of the technique of spirit fresco illustrated by precise details of Lord LEIGHTON'S work at the Victoria and Albert Museum.

Encaustic painting receives but a bare mention in Mr. WARD'S book, but is far older even amongst moderns than spirit fresco, having been described in a paper by Miss E. J. GREENLAND, read before the Society of Arts in 1786, and we know that it was used by the Greeks, though their precise method is lost. In Miss GREENLAND'S process the medium was a mixture of gum arabic, gum mastic and wax dissolved in water, and the work was therefore always liable to be injuriously affected by damp air or moisture on the surface, in which respect it was inferior to spirit fresco, which is impervious from the front and affected only by damage to the plaster.

The latter half of Mr. WARD'S book consists of technical notes on the composition, colour and present state of some Italian frescoes, copiously illustrated by admirable illustrations, both in monotint and colour, so that we have an interesting account of some of the best old work as well as valuable instruction in technique sufficient to enable anyone to practise painting in either buon-fresco or spirit fresco.

STEELWORK.—VI.

By C. V. CHILDS, A.M.I.C.E.

Girders.

THE greater the number of stanchions the less the weight of the steelwork, may be laid down as an axiom in steel design. The weight of the stanchions is little affected by increasing their number; they have, in any case, to carry the total dead and live floor loads, which are practically constant quantities, independent of the number of stanchions which support them. The total load of a floor is a certain quantity of tons, whatever the number of the stanchions may be; the only difference that affects these is due to, the greater the number, the smaller the sections will be, and consequently their carrying capacity; or in other words the allowable stress will be slightly less than for fewer stanchions of larger area; the difference would affect the cost but slightly. With the girders however it is a very different matter; the farther the stanchions are placed apart, the greater the spans, and to an even greater extent is the steel increased that is required to span them.

Taking the case of girders carrying a uniformly distributed floor load, their strength and consequently weight is dependent on the product of their span and the total load, which again depends on the span; that is to say, the requisite moment of resistance of the girders is proportional to the square of the spans. Their weight, however, will not follow this rule, owing to the fact that the longer the span the greater depth of girder will be required to give it the necessary stiffness. The nearest approach that can be made for a general rule, governing the weight of the girders, is that this is proportional directly as the square of the spans and indirectly, to a certain extent, as the depth of the girders. As an example, to carry a load of 15 tons on a 10 foot span, a 10 inch by 5 inch rolled-steel joist weighing 30 lb. per foot run would be required; by doubling the span the load would be 30 tons (the width of the floor bay remaining the same) on 20 feet, requiring an 18 inch by 7 inch joist at 75 lb. per foot run, thereby increasing the weight of the girder two and a half times. To produce equal strength (the question of stiffness being neglected) for an equal depth of girder, viz., 10 inches, would increase the weight fourfold. In all probability neither of these two girders would be employed in actual practice, the former on account of the loss of headroom, owing to its depth, and the latter for want of stiffness for the opposite reason. Two joists 14 inches by 6 inches, weighing together 92 lb. per foot run would probably be selected, so that in doubling the span the weight of the girder has been trebled; at the same time the loads to be carried by the stanchions, whether two or three in number, remain the same.

Another most important point to be considered in regard to making the girders of long spans is that not only the weight, but in almost all cases the cost, of the steelwork is increased. Where for short spans plain joists would serve as the girders, for long spans compound girders would become a necessity; the weight is thus not only increased, but the cost per ton of the latter would exceed that of the former by at least twenty per cent. Take a similar case to that stated above, but for 14 and 28 feet spans carrying 21 and 42 tons respectively. For the two 14 feet spans, a 14 inch by 6 inch R.S.J. 46 lb. per foot would cost about 4*l.* 6*s.*; whereas for the 28-foot span a compound girder, composed of one 16-inch by 6-inch R.S.J. and cover plates, weighing 143 lb. per foot run, would be required costing 16*l.* 2*s.*; which shows that the cost has been increased nearly fourfold; from this it is apparent that the luxury of having but few stanchions can only be attained by paying heavily in excess of what the steelwork would cost in the case of stanchions placed closer together.

Architects should give this point especial consideration. The first thing that is necessary to be done in the steelwork design (and in the majority of cases this is settled before the engineer appears on the scene) is locating the positions of the stanchions, which are dependent on the general planning of the building, and therefore taken into consideration in the architect's design. The chief difficulty usually lies with the ground floor plan, where shops, banqueting halls and the like occur, in which an open space free from all obstructions is the chief desideratum.

These large areas necessitate large girders over them and advantage may be taken of this, and the increased number of internal walls and partitions, to augment the number of stanchions in the upper storeys. A comparatively small amount of extra material in the flanges of the large girders will, by enabling an additional stanchion to be carried, save a considerable amount of steel by reducing the spans of the girders for the upper floors. This is again on the principle that one large girder is more economical than many smaller ones of the same span. By this means, too, the depth of the girders in the upper floors may be considerably reduced, a very important consideration when it comes to the matter of the internal decoration and the plastering.

Frequently there is a wide difference of opinion between the architect and the steelwork designer in regard to what the depth of the girders should be. Naturally the architect is desirous of keeping the joists and girders as shallow as possible, in order to avoid having to case these in, where they would project below the ceilings, as well as for the sake of the appearance of the ceilings; also in order to reduce the depth of the floor to a minimum. Increasing the thickness of the floors may mean losing a course or more of brickwork in the heights of the rooms. Against this must be placed the points the designer has to consider; apart from the economy gained by using joists of greater depth, the most important consideration is the question of stiffness. A spring-board is strong enough for its own purpose, but this is hardly the principle on which to design floor girders. The depth of the main girders should be at least, unless in exceptional circumstances, one-twentieth of the span; 1 foot in depth for 20 feet in span is a convenient proportion to remember. It would be better if the rule could be adhered to for the cross joists as well; but in their case, when the concrete is filled in between them, this helps to give them rigidity.

One instance that frequently occurs may be mentioned, where the temptation is great to use too shallow girders; and that is, where they carry a flat roof over a long span with a skylight in the roof. As regards strength the girders may be comparatively small, but where glass is concerned, rigidity is essential. It is no uncommon thing for trouble to occur by reason of the glass cracking—it may be purpose-made panes for curved skylights—owing to a little false economy or want of sufficient depth in the steel girders.

Talking of purpose-made goods, this term is specially applicable to girders; they are requisitioned to bridge the gulf under every kind of condition. There is the roof truss in all its various forms; the lattice girder; the plate girder; the compound, composed of joists and flange-plates; even the bridge truss, built up of its component members, is occasionally required in architectural steel construction.

The bridge truss may be disposed of in a few words, because it is seldom that this type is economical in building work. One is tempted sometimes to use it where it might be buried in a partition wall at the first floor level, in order to avoid the equivalent plate girder, or compound, breaking down too far into the ceiling of an important room in the ground floor. But, as a rule, it will be found more economical to relieve the first floor girder by carrying up the stanchions and placing an additional girder at a higher level.

The reason of this is the high cost per ton of the bridge truss; also the assembling of the members and the large amount of rivetting to be done on the site. Even in a case, as stated above, it is a difficult matter to design, owing to the openings for the doors interfering with the proper arrangement of the diagonal or vertical bracing.

Digitized by Google

Undoubtedly the best design for roof trusses is to make each members, whether ties or struts, of two steel angles, and to avoid the use of flat bars; this not only makes a more rigid truss, and less liable to damage during transit and erection, but the jointing of the members, by means of gusset plates is made simple and symmetrical. The use of flat bars always gives a meagre and flimsy appearance to the trusses; where they are used it would be an advantage to join the bottom tie at its centre by means of a union nut, for the sake of adjusting any inaccuracies of workmanship. It frequently happens that when the trusses are first erected, the flat bar tie appears to be flapping about and not settling down to its work, until the weight of the roof comes on the truss. Very slight inaccuracies in the length, which are not adjustable, may cause considerable unevenness in the line of the ridge.

The use of the union nut might with advantage be introduced more freely into English work. In America the sleeve nut, or turnbuckle as it is termed there, holds a recognised position in steel design; it is drop forged to standard sizes and the works are equipped for upsetting and tapping the ends of bars or rods to be connected and adjusted by the sleeve nut. Unfortunately, but few constructional works in England are so equipped, consequently this useful member has to be avoided by the designer. Where appearances count, the most graceful looking trusses are those whose tension members are round rods with forged eyes, but this unfortunately adds considerably to their cost. One point requires attention, and that is to see that the purlins take their bearings as nearly as possible over the joints of the bracing members to the main rafters; unless the rafters are increased in size to withstand the bending, caused by the purlins being placed intermediately between the joints, an unsightly appearance may be given to the roof, owing to the rafters sagging.

Purlins are frequently troublesome to design. Architects are almost always in favour of spacing the trusses far apart; this means long purlins, the loads are usually light and the difficulty is to secure enough stiffness in the purlin section. In an ordinary roof the worst that can happen is an uneven surface, due to the sagging of the purlins; but when there is glazed work in the roof, it becomes a serious matter, owing to the danger of the glass continually breaking. One means of overcoming the difficulty is to truss the purlins, but this gives the interior an unsightly appearance; the better way is not to space the trusses unduly apart.

Lattice girders are but seldom used in the steelwork for buildings; they are more adapted for carrying light loads over long spans. In building work the loads are as a general rule too heavy for this form of girder. Heavy loads mean heavy cross-bracing members, and consequently large gusset plates at the joints, so that there shall be a sufficiency of rivets to transmit the strains. This destroys the effect of what it is desired to gain by using lattice, in place of plate, girders, viz., lightness in appearance. In fact, in almost all cases it is for the sake of appearances, and where the girder is exposed to view, that the lattice girder is used, in order to avoid the solid and heavy effect produced by the plate girder.

The chief purposes for which lattice girders are employed in buildings, are for carrying roof trusses over long spans, also it is frequently used to carry foot bridges between separate parts of a building; in some cases, too, it may be used for the purpose of obtaining borrowed light, the external side of the girder being protected by vertical glazing.

THE SOCIETY OF ARCHITECTS.*

IT may be taken as an axiom that the Romanesque style developed almost entirely, if not entirely, in the districts which, some 700 years before the period now under consideration, had been under the dominion of Rome. There had been at an earlier period, and there were again in the eleventh century, two principal trade routes throughout Europe, one of these lying along the Rhine Valley, while the other traversed the Riviera and the South of France. From each of these main arteries trade and culture spread like a fan over the land, until the intermingling of influences in Mid France and Northern France was so complete that they became well-nigh indistinguishable. Speaking generally, the detail of this time throughout the whole Romanesque period now remaining along the Rhenish route is of a Roman type. Of mouldings there are scarcely any. A capital, from Soissons, gives a fair idea of what might be expected to be found throughout the whole district in which the Roman influence was in predominance, having a certain amount of Byzantine feeling in the shape of the acanthus leaves. The work is essentially Classic, with acanthus foliage and suggestions of volutes in the cap, and the use of all the ordinarily understood Classic enrichments, debased but recognisable. In this district the carving is Roman; it is true carving, in which, as a rule, the foliage projects well from the background.

Along the southern trade route, although it was a district where Roman remains must at that time have existed in innumerable quantities, the character is much more Byzantine. The surface of the stone which is carved is clearly discernible, the enrichments being obtained by sinking the background beneath it and by the use of the drill, as in much of the Byzantine work; while the cushion capital, itself a Byzantine feature in its enriched form, is found rather than the Corinthianesque.

This Byzantine stream of influence, as it neared the coast and travelled northwards, was subjected to another, an apparently Scandinavian influence, due, it may be supposed, to the fact that the coast-line of Western Europe was invaded by the same northern pirates as overran England and founded the Anglo-Saxon race. The result is seen in perfection in Poitiers. One of the capitals from the richly carved west front of the church of Notre Dame in that town consists of a cubical block of stone which has been roughly shaped into the cushion form so as to fit upon the semi-circular shaft, and has then been carved by cutting in the background so as to represent grotesque birds of an undoubtedly Scandinavian character, while the abacus above is enriched with a crude Byzantine interpretation of the anthemion.

Further north, particularly in Normandy, the Scandinavian influence is even more apparent, the details being almost identical with those commonly found in England during the same Norman period, their origin being in many cases easy to trace back to the forms of twisted wirework or to embroidery.

Detail of this description is, however, never found in connection with what we know as Gothic architecture; but the Gothic foliage, as it occurs in France, appears to have developed almost directly from the pseudo-Corinthian capital found in the Western districts under Rhenish influence. In the example already referred to at Soissons the acanthus is overshadowed by a broad leaf, and from this combination it is easy to recognise the source of the rich broad-leaved capital in very common use. In an example in the choir arcade of Lisieux Cathedral the leaves are arranged in tiers one above another as in a Corinthian capital, curling over at their tips much in the same manner as do acanthus leaves in Classic work, but without serration and more resembling the terminations of the fronds of the hart's-tongue fern.

At this date there is a general consensus of opinion that the carvers, whether in England or on the Continent, were beginning to obtain their inspiration from Nature. It is not so generally recognised that it was undoubtedly the spring foliage from which this inspiration was taken. Examination of a large number of examples must drive any careful observer to this conclusion. The first leaves were broad, certainly, but they were not fully developed leaves, as the curled-over tip indicates; and as the thirteenth century proceeded, the leaf became more narrow and the tip developed to a half-open series of leaf-buds known as the "Crochet" (or hook) capital. There is almost invariably an indication of Corinthianesque origin in the formal arrangement round the shallow bell cap, which is also of Corinthianesque type; but the fact that the foliage is natural and that of spring is incontestable, just as much as it is in England.

Gradually, too, as time went on, the foliage opens, as it does in Nature, when spring merges by imperceptible degrees into summer. A certain formality of arrangement is still retained, though in some of the grandest examples the foliage now occurs in the form of a scroll serving as a horizontal string. The use of foliage is, however, not exuberant as it is in England, except in crockets.

Strangely enough, as the thirteenth century merges into the fourteenth, the foliage became more and more like that of summer, until a perfectly summer foliage was developed; for instance, in a capital in the apse of St. Alpin, Chalons-sur-Marne, which shows vine leaves growing as a wreath round the capital and young grapes among the leaves. The capital has entirely lost the bell form and has reverted to that of the cushion, while, as in the earlier times, the carving no longer stands out, but effect is obtained by inci-

sion of the background. As a general rule the foliage of this period is flat in effect in France; in England, while it also here represents summer at the same date, it is crisp and fully undercut.

It may be remarked that of this time there is no great amount of Gothic detail to be found in France, nor in fact much Gothic building either, for the country was overrun during the early part of the fourteenth century with English troops, who ravaged and pillaged wherever they went, preventing all attempt at building operations, and immediately on their departure the "black death" came, leaving utter ruin in its train. When it was desired to enrich the porches of Bourges towards the end of the fourteenth century, the Portuguese were called in to do the work, with the effect of extraordinary cusping and the introduction of a large amount of small enrichment, both of foliage and figures.

During the whole of the thirteenth and fourteenth centuries figure carving and sculpture were developed in France as nowhere else, with extraordinary breadth and dignity and extreme simplicity. They are mostly to be found in the great cathedral doorways, as majestic figures of Our Lord and the Apostles, as groups of angels, and illustrating scenes from Bible history and the lives of the saints. They are also to be found in many unexpected places, notably upon buttresses and pinnacles. Human grotesques are also common, and animal grotesques are more so, occurring sometimes as gargoyles, but quite as often as mere ornamental groups, say, of scampering rabbits, mice, or other animals, all crisply and clearly cut, indicative of close observation and an intimate knowledge of field life.

During all this period the mouldings changed scarcely at all, in this way differing widely from those in England. Romanesque work, where based upon the Roman, was perfectly plain, the arches, in receding planes, being usually rectangular in sectional outline, enriched with some carving possibly, but rarely moulded at all; while in Western France, and subsequently throughout the whole district under consideration, the angle roll and the slight surface hollow, which are associated in England with Norman work, became common, if not universal. The strange thing is that this extreme simplicity was retained throughout the whole of the thirteenth century, being only modified on the lines of our Early English mouldings in rare instances, when the English influence can generally be traced, as in the cloisters of Mont St. Michel.

Recognising this, that what we call Gothic mouldings were in the thirteenth century not fashionable on the Continent, it is not astonishing to find that the development in the fourteenth century was only such as would naturally follow out of the Romanesque angle roll. It may be thrown out as a suggestion that it is largely due to the simplicity of the mouldings that we have such exceedingly dignified pointed work in France in comparison with the delicately beautiful English arcades.

In the fifteenth century, when English mouldings were flattening and deteriorating, those of France developed in an entirely fresh and Gothic spirit of great freedom; with long and narrow bowtells projecting in many directions apparently without rule; with deep hollows sometimes narrow and sometimes wide, and with a general avoidance of all symmetry. The effect is wiry, but it is frequently extremely beautiful, the narrow mouldings being allowed to interpenetrate as circumstances might require, and each having its own independent base, which dies into a greater base belonging to a group. There is a theory abroad that when the art of building revived in the fifteenth century the detail of tracery, at any rate, was evolved out of that of the English flowing Decorated style, owing to the influence exercised by Englishmen who had remained after the wars. This may be true of the tracery, but the mouldings and the carvings are essentially distinct. They seem rather to indicate that the French character revived when war and plague had passed, with the energy of a species of false youth, impetuous to recklessness, but captivating all the same.

The foliage suddenly lost the flatness of the period before the English invasion and took on the clean undercut character and crispness of that of England in the fourteenth century, giving to it, however, the effect of autumn leaves instead of those of summer-time. Nothing could exceed the brilliance both of execution and design of such work as the thistle scroll round the north door of the west front of Tours Cathedral. The leaves are unquestionably autumnal in character, fruit and nuts growing among the leaves, while the stem is knotted and gnarled. There is much of this late work at Abbeville, at St. Maclou, at Rouen, and in the south doorway of Beauvais Cathedral, where an example occurs of the bare boughs without foliage being utilised as cusps, the leaves having fallen entirely away, and the indication being that the winter of Gothic architecture has arrived.

CHICHESTER CATHEDRAL.

SOME interesting particulars concerning the work of restoration needed to be carried out at Chichester Cathedral were given at a meeting of the executive committee of the Restoration Fund.

The financial report showed that of the 1,651*l.* 2*s.* 11*d.* promised in connection with the restoration of the campanile, only about 60*l.* remained to be collected by instalments. Of this sum 1,415*l.* had been made to Messrs. Vick on account of their total claim of 1,880*l.* 17*s.*, so that with other expenses the amount now at the bank was 40*l.* 17*s.* 7*d.*, which with the unpaid instalments left the balance in hand to the present of 94*l.* 10*s.* 5*d.*

The condition of the cathedral was reported upon by Mr. Gordon Hills, the surveyor, who suggested that priority of action be taken in the following matters:—(1) The completion of the general repair and pointing of the walls, including dealing with the various cracks and settlements; (2) the west front and south-west tower; (3) the general repair of the vaulting; and (4) the repair to the leadwork of the cathedral roof. With regard to the first item Mr. Hills pointed out that the general repair and pointing to the walls had been steadily carried out since 1902, and that the whole of such repairs and pointing had been completed with the exception of the west front and the space between the south-west tower of the south transept.

Reporting upon the vaulting of the cathedral Mr. Hills said his father had as long ago as 1892 called attention to certain old cracks in the nave vaulting, originating at least 300 years since. As they had recently shown symptoms of instability he had caused a scaffolding to be erected, and was at the moment engaged in examining the condition of the vaulting. In view of the doubtful condition of the vaulting he advised the postponement of the work on the leaden roof, as the jarring or disturbance might tend to upset the equilibrium of the portions of the vaulting now under examination. Mr. Hills, however, was emphatic in his opinion that no danger whatever was to be apprehended to the public by the condition of the vaulting.

The urgency of the work to the roof was not so great as was apprehended, although no doubt it would be necessary to prepare for it in the near future. Constant care and attention had rendered the roof water and weather proof beyond expectation, and with continued care the roof might fairly be expected to remain in watertight condition for another ten years at the least. The roof had been materially strengthened by the rebuilding of the north-west tower and the recent repairs at the west gable and adjoining roof truss, and he felt certain there was no urgency for dealing with the lead work at present. But when once taken in hand the releading must be completed, whatever might happen, whereas, on the other hand, the repair of the vaulting could be done a bay at a time, and he thought it would be a great advantage to the appearance of the interior to be rid of some of the cracks, and loose and patchy plastering on the vaulting, besides being a work which the subscribers could see and appreciate.

After some discussion it was agreed, on the proposition of the Bishop, "That the repair of (*a*) the west front and south-west tower should first be taken in hand; then (*b*) the remainder of the pointing; and afterwards (*c*) the bay of the vaulting, which is at present receiving attention, should be properly dealt with. It is understood that a further appeal for subscriptions will be made shortly to the diocese.

The Henry Saxon Snell Prize was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is to be awarded by the Council of the Royal Sanitary Institute at intervals of three years, the funds being provided by the legacy left by the late Henry Saxon Snell, F.R.I.B.A. The prize will consist of 50*l.* and a medal of the Institute, and is offered in the year 1909 for an essay on "The Principles of Heating and Ventilating Public Buildings, with descriptive details and illustrations of the best systems." The essay is to consist of not more than 5,000 words. Two competitors of different professions or crafts may join in sending in an essay and plans. Essays must be delivered before 4 P.M. by August 31, 1909, addressed to the Secretary of the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.

ANOMALIES IN BY-LAWS AND REGULATIONS WHICH AFFECT SANITATION.*

(Concluded from last week.)

AMONGST the enormous variety of regulations and practice in connection with all matters concerning house drainage, the provision or deletion of the intercepting trap finds prominence, and the inquiry at present in progress as to its advantage or otherwise under all conditions, provides probably the only necessary exception which may be required to vary owing to local conditions in all that concerns the subject under notice.

There is, however, no room for a variety of form or size in this appliance, nor any exception required in condemnation of all the various forms of this trap at present in common use.

The necessity of the intercepting trap exists in its being the junction between two separate and distinct responsibilities, i.e., the public sewer and the domestic drain, and its trap is against the foul air or gases from the public sewer side of the connection.

To consider this trap as a last line of defence against the misuse of the domestic drain is as unnecessary in argument as it is useless to effect that object with either convenience or safety.

It is clearly wrong to anticipate and make provision for misuse of the domestic drain at any point so far removed from those at which the different pipes or fittings discharge into it. These are (or should be) already provided with gratings or contractions which will indicate the presence of any total or partial obstruction at the earliest possible moment, at points where they or their effects can be easily seen and removed.

That the usual form of these primary safeguards is not to be depended upon does not in the least warrant the provision of an enormous receptacle at the other end of the system, but rather reminds us that they should be made to efficiently do their work at a more convenient point, and one at which there will be less ultimate danger.

A domestic drain cannot be constructed to take scrubbing brushes, bunches of flowers, underclothing, mop rags, fat, &c., and at the same time to fulfil the necessary conditions to ensure effective sanitation; any attempt to serve the dual purpose must be fraught with disaster, and bring about the maze of complications which the duplication of unnecessary safeguards has been shown to involve.

If the purpose of the intercepting trap as a last line of defence to the misuse of the domestic drain is disregarded, the capacity and form may then be limited on the house side of the drain to ensure the whole of its contents being entirely displaced under normal conditions of use, and as the most frequent volume suitable for this purpose is from the discharge of a water-closet, the calculation of the correct capacity may start below a limit of 3 gallons.

For obvious reasons, it is not advisable that the diameter of the full way through the intercepting trap for an ordinary dwelling-house should be less than 3½ inches or more than 4 inches, and this diameter and the desired limit of capacity will fix the depth of seal available.

Although rather a general omission than an anomaly, the absence of any restriction in the number of gullies which may be provided is a matter intimately associated with all that concerns effective sanitation.

This would dictate the necessity of a provision limiting the number of gullies, and each to a minimum capacity for its purpose, as also to ensure that the volume of water will be concentrated with the double object of flushing thoroughly the gully and the drain to which it is connected.

Except in the case of traps which are required for special purposes, such as the retention of grease, all gullies and traps should be of such a form and capacity to ensure that their whole contents are displaced every time when normally used, and the water should be delivered in such volumes and in such a position as to secure this object.

It will be found in practice that with the detached or semi-detached type of dwelling-house one, or at most two, gullies can be made to suffice if all the unfouled water is collected and made to discharge at one point.

To do this it is advisable to collect all the unfouled water on shallow drains without traps or gullies from the rain pipes, and deliver the whole of the water over one or (as pointed out) at most two gullies.

This system would also secure another and most important condition in regard to gullies, which is not dealt with by any by-laws.

Unless for reasons quite impossible to avoid, no gully should be left dependent upon rainfall alone to secure its seal, but should always receive the discharge of some pipe that will ensure its being continually charged and its contents displaced, as instance the discharge of sink, bath or lavatory wastes.

In the matter of soil or fouled water pipes above ground, similar objections can be quoted to those applied to underground drains.

The regulations controlling these vary in different though adjacent districts from light iron or rain-water pipe strength to strong iron, and are for soil pipes usually 4 inches diameter, whether for a number of closets or a single one only, sometimes wholly of iron, or the portion above the top discharge inlet which forms the vent, made of drawn lead pipe.

In jointing these pipes and their fittings the practice embraces putty and paint, with or without spun yarn, lead wire or molten lead, stemmed in with a caulking tool, Portland cement, sulphur and iron fillings rusted in, but where it is necessary to join iron or lead to earthenware the putty and paint joint is the most usual practice.

It is unnecessary to prove that all these methods cannot be right, and that only one, or at most two, will under any conditions effect the desired object, and that in general practice the weakest form of joint is usually found in the most inaccessible and consequently most dangerous positions.

The infinite variety in forms of w.c.'s, sinks, lavatories and baths is open to criticism in an equal degree, and in all cases it would appear that the first object of their use has been made subservient to other conditions. Although in these there may be permitted greater limits of variation without impairing their efficiency than in the case of drains, there is no apparent room for this enormous variety of forms to provide what is in all cases a common object.

Whilst forms of connection or disconnection and the provision of traps may be within the scope of some by-laws, much that appertains to these accessories is usually confined to the particular fancy of the official, but this is not guided by any connected standard or principle which obtains beyond his own district.

To deal only with the most common of these fittings, the w.c. apparatus, and which is directly connected with the drain, will serve as an illustration of the discomfort, if not danger, which attends a departure from principles which direct that simplicity in design and action and economy in area (to be fouled or flushed) should form the chief aims if these fittings are to fulfil their several objects efficiently.

There is no w.c. apparatus on the market which fulfils these conditions, either alone or in association with its several parts.

Some forms depend upon the water area in the pan (a necessary attribute), but not defined by any general acceptance of standard by local authorities. (I have been approached by officials who are members of the Association of Sanitary Inspectors to advise them upon this point.) The water seal is of a variety of depths, but not governed by head of flush or type of flushing tank, quantity of water, capacity of outgo and conditions of soil pipe or drain, all of which must have the most intimate relations one to the other in order to secure the objects of by-laws and regulations. Further, with these conditions correctly adjusted, not only will the operation of flushing the closet be assured, but the cleansing of the drain and its mechanical ventilation made a frequent certainty. Although not so immediately relevant to the subject of the paper, the regulations of the water authority impinge upon those of the building and sanitary authorities over the quantity of water allowed to flush out the w.c. apparatus, but whilst the volume will be usually defined and is often a point of contention between the different officials, its effect will be to some extent controlled by conditions that do not receive the attention of any official or department.

The value of the water to perform its object will depend upon the height of the flushing tank above the closet, and also the diameter of the flushing pipe and the number and radius of the bends in same.

Beyond this the external shape and size of the closet, pot or pan will also materially affect the attainment of its objects. After this the form and size of the outgo trap and the size of the pipes will influence the value of the flush in carrying the contents of the water-closet to its ultimate destination at the end of the branch or into the disconnecting chamber, and also to effect the necessary displacement of air in the drain or soil pipes.

* A paper by Mr. William Challoner, president of the Institution of Plumbers, read before the Midland Association of Local Government Officials on February 8.

Digitized by Google

The jointing of the earthenware of the closet pan to the lead or iron is always a weak point, and added to the difficulty of joining such dissimilar materials is the awkward position in which this junction always occurs and the liability to slight movement to which the closet pan is subject by the shrinkage of the floor upon which it stands, which is most commonly of wood.

The omission from the by-laws in many districts of regulations providing anti-syphonage pipes, and the variety of opinions held of their necessity by sanitary or building inspectors, will further affect the action of the w.c. apparatus (similarly, the absence of provision to supply displacements of air affects traps which may occur in other parts of the drainage system).

These are but a few instances which serve to illustrate the anomalies and variation of interpretation to which local by-laws are subject, as also to show that the different appliances, owing to their faulty design and combination, give little or no evidence of that practical knowledge which can only be acquired by an intimate association with all the circumstances of position and conditions which will ultimately test their utility.

In the same way the form and design of such fittings in common use as baths, urinals, slop-sinks, lavatories, are each in their way open to the same criticism as the accessories described, and all leave ample opportunity for revision on common-sense lines of simplicity. There is no room for originality or fads in this matter; in all there is a minimum of size and form which will best secure the object permanently. Certain materials are suitable under all conditions, and the choice of these should not be subordinate to fads or fashion created by those who have the least practical knowledge of their ultimate conditions in use.

It requires little argument to prove that the value of teaching technical subjects which include the principles of plumbing, sanitation and building construction is discounted by the contradiction which the generally prevailing want of standard in everyday actual practice involves and for which anomalies in by-laws are in great measure responsible.

It is easy to imagine the position of a workman or his directing head who has at the technical classes been taught certain principles which, if carried out in actual practice, would be condemned by the official whose duty it is to inspect and approve the work. The common result of this position is that the plumber puts aside the knowledge which he has been at some considerable pains to acquire and which also represents not a little cost to educational authorities and waits to be directed and inspected.

Some of us for the past few years have been intimately associated with technical education, and our efforts have been directed to the object of perfecting the knowledge of the working plumber and directing heads of plumbing firms, instead of relying (as was somewhat the practice in the past) upon the training of the inspector, realising that no amount of official inspection could produce good work from an indifferent workman, but we have not gone far before coming face to face with the anomalies which exist between principles and practice many by-laws embody and the unsuitability of appliances and material obtainable to carry out the work. The drawing up of a standard specification embodying the principles to which allusion has been made would present little difficulty, as in the case of determining the size or capacity of drains. Most by-laws appear to assume that a drain or its accessories cannot be of too great a capacity, which is an entirely wrong principle, and from this fundamental error arises most of the complications which appertain to the subject of sanitation in the conveyance of polluted matter or elements within the curtilage of the domestic drains and often beyond it.

These capacities and sizes should be determined in relation to the work they are intended to perform, instead of, as at present, creating a series of possible dangers by providing for emergencies that may be more easily dealt with by other means. The common practice of providing for abnormal rainfall and carelessness in use in and about the domestic drainage system is to be condemned for obvious reasons. It is far better to leave the risk of the latter to a salutary lesson that will prevent its recurrence than to make provision for emergencies which will themselves all the time constitute a source of hidden danger.

Most sanitary fittings and appliances may be designed to prevent the passage of any complete or partial obstruction beyond a point when it might be easily removed; at present it is often a case of digging up the drain or almost pulling down the house when a stoppage occurs.

In many instances means of warning might be provided (much on the lines of the safety points in an electrical installation) whereby a condition of ultimate discomfort or danger would become at once so apparent as to compel attention.

Under present conditions the warning depends upon a more or less chance visit of the sanitary inspector, or the belated one which is conveyed by the notification form of infectious disease sent by the medical attendant after the damage is done.

In conclusion, I beg to convey my appreciation of the honour conferred upon me by your request to read a paper, and venture to express the hope that some means of co-operation may be found between the important public bodies which are here represented and the craftsmen I have the honour to represent.

IDEAS IN THINGS.

MR. C. F. A. VOYSEY'S second lecture on "Ideas in Things," in connection with design as applied to completed work, was delivered at Carpenters' Hall, on Wednesday last, the 3rd inst. In the building of a home, he said, if the money at disposal would not pay for oak joinery everywhere, he would have it nowhere, as to have the entrance and reception rooms in oak and the rest deal at once suggests the "whited sepulchre." As Augustus Welby Pugin remarked of the dissenting chapel-builders of his day, "And then they thought the Lord to cheat by building the back parts shabby." The same material for entrance hall and lavatory floors will avoid the sensation of the change and loss of repose. Oak that was once the most durable and plentiful building wood in England can now be obtained from Austria better seasoned and much softer to work. It is more quickly grown than English oak, but not so beautiful. In old times when the carriage of materials was more costly, local material was more used, and only the vain rich made use of imported material. A charm attaches to the characteristic colour and texture in the old buildings of different districts, and there is a harmony in nature's materials. After alluding to the many trivial details of home and domestic life, in the belief that great ends have small beginnings, and that if the thin end of the wedge of spiritual significance can be driven in among the common objects of life, it will lead to noble thought and feeling, by which one may hope to advance in character and conduct, the lecturer concluded his interesting address, of which we can only give the above short abstract owing to pressure of space, by saying that the only instruction he had to give was to think of the needs of the spirit more than the needs of the flesh; then, and then only, would there be witnessed really good and great architecture, really good carpentry, and really good work of any kind.

The Design Club, which was formed a few months ago for the purpose of bringing together artists concerned in practical design, has made good progress, and its new premises were recently opened at No. 22 Newman Street, Oxford Street, by Mr. Lewis F. Day and Mr. A. Lasenby Liberty. The new premises are well equipped for the social requirements of the members. It is intended to open a "life" room and further develop the practical side of the work of the club.

The Cambridge University Senate recently considered the plans for proposed literary and mathematical lecture-rooms and departmental library. It is proposed to erect the building on what is left of the Mortlock site, next to the new examination halls. The suggested building will contain eleven lecture-rooms—the largest of these will have seating accommodation for nearly 300 students—a common room for professors, readers and lecturers, and three small rooms for classes and interviews. The departmental library has a floor space of 2,250 square feet. Some of the speakers expressed a hope that no expense would be incurred on architectural features.

A Blue Book recently issued gives statistics as to the cost of public education in England and Wales. The principal amounts include contributions towards local science and art scholarships held in secondary schools, 42,219*l.*; technical institutions, schools of art, day technical classes, art classes, and other schools and classes for further education, 456,573*l.*; scholarships, exhibitions and prizes, 10,252*l.*; Royal College of Science, London, 24,843*l.*; Imperial College of Science and Technology, 5,783*l.*; Royal College of Art, 11,312*l.*; museums and circulation of objects for exhibition, 60,069*l.*; works and furniture (museums, Royal College of Science and Art, Solar Physics Observatory, &c.), 22,484*l.*; Geological Museum and Geological Survey, 21,255*l.*

NOTES AND COMMENTS.

MR. H. STUART JONES, formerly Director of the British School at Rome, claims to have established certain definite facts about the "Ara Pacis," the famous altar erected by CÆSAR AUGUSTUS in 9 B.C. Mr. JONES regards it as certain that no discoveries were really made on the site of the altar till 1568, when several slabs and the relief of Tellus and the Aurae, now in Florence, were found. He disputes the view that the reliefs, originally belonging to the Della Valle collection and now walled up in the garden-front of the Villa Medici, belonged to the Ara Pacis. He believes that the figure usually identified as that of AUGUSTUS was intended for the *rex sacrorum*, and allocates the relief of Tellus and the Aurae to the east face of the altar and the Lupercal with the fig-tree to the north side.

THE value of the ozone process for the sterilisation of water appears to have been established by the experiments made last year by M. COLMET DAAGE, the chief engineer of the technical branch of the water supply and drainage department of the city of Paris. In these experiments, the results of which have been recently published, DE FRISE sterilisers were used with ozonisers of the Siemens de Frise type. With sand-filtered water from the Ivry waterworks containing 255 bacteria per cubic centimetre, sterilisation reduced the number of bacteria to about 2 per cubic centimetre. With water experimentally contaminated to the extent of 11,000 bacilli coli per cubic centimetre, only one of these germs escaped out of 110,725. When muddy river water from the Marne was added to the extent of about 15 per cent. to the drinking water, producing a mixture containing 10,735 bacteria per cubic centimetre, the ozonised water gave 35 bacteria per cubic centimetre without a single example of colon bacillus. The cost of purification in the experimental installations treating 100 cubic metres of water per hour with electricity at .11 franc per kilowatt averaged .0184 franc per cubic metre of treated water, but M. DAAGE estimates that treating 300 cubic metres per hour with cheaper electricity at .055 franc per kilowatt, the expense would be only .0072 franc per cubic metre of water treated.

VOLUME III. of *The Architects' Law Reports and Review*, by ARTHUR CROW, F.R.I.B.A., and A. J. JENKIN, barrister-at-law, has now been issued, and deals with the more important cases affecting architectural practice and decided in the year 1906-7. As in the preceding volumes, value is given to the reports by the inclusion of photographs and drawings used in various cases. Amongst the most important cases reported are those of ANKERSON *v.* CONNELLEY and ANDREWS *v.* WAITE, both dealing with the effect upon the rights of ancient light brought about by alterations of the dominant tenement; and Attorney-General *v.* METCALF & GREIG, determining the application of certain sections of the London Building Act, 1894. The text is given of the Public Health Acts Amendment Act, 1907, with useful notes on various sections by the legal editor. Critical notes are also included of clause 45 of the Housing, Town Planning, &c., Bill of 1908, and of Part III. of the London County Council (General Powers) Bill of 1908.

ILLUSTRATIONS.

HARCOURT HOUSE, CAVENDISH SQUARE, W.

THIS new building has been erected in Cavendish Square on the site of the old Harcourt House (the residence of the Duke of PORTLAND), and is divided into twenty-eight flats. The main elevation is carried out in Portland stone supplied from the quarries of the Bath Stone Firms, Ltd. The floors of hall, dining-room, and drawing-room are laid with parquetry. The entrance vestibule, main hall, and staircase are carried out in white Pentelic marble with mahogany dado. The roof is covered with green Westmorland slates. The hot water for heating and domestic supply is derived from a central heating chamber. There are service and passenger lifts, supplied by R. WAYGOOD & Co., LTD. The architects are Messrs. GILBERT & CONSTANDUROS, Finsbury Square, E.C.

SMALL COUNTRY HOUSE AT POTTER'S BAR.

THE small house illustrated to-day has been erected on an estate at Potter's Bar, Middlesex, which is being developed in order to provide detached houses of an economical description on half-acre plots within easy access of town. The accommodation provided is shown on the plans, a feature being made of the square staircase hall. The ground floor rooms are panelled to a height of 7 feet with Oregon pine. The house is solidly erected with 14-inch external walls, rough cast, and the roof is covered with red tiling. There are no plaster ceilings to the ground storey, the joists being stained, and supporting two layers of floor boards with felting between. The architects are Messrs. BANISTER FLETCHER & SONS.

CHURCH OF ST. JOHN BAPTIST, HOLLAND ROAD, KENSINGTON.—REREDOS IN CHANCEL.

THE original reredos was erected by the late JAMES BROOKS in 1892, and was then separated from the walls of the apse by an ambulatory. Subsequently it was surmounted by a statuette of the Good Shepherd and twelve figures of angels, and the arcades were filled with painted panels of saints and angels given as memorials. As it was found that in its first arrangement it encroached too much on the floor space of the sanctuary, it was in 1899 re-erected with considerable modification close to the apse walls, the height was reduced, and four of the angels were relegated to the western gallery. These changes resulted in the reredos appearing too flat and ineffective, and it was determined to again re-erect it, with increased height and as much relief as could be obtained without unduly reducing the floor space. With this object in view the three sides have been separated by projecting piers carried up above the general line, and the whole has been raised on a new arcade, which has been extended beyond the line of the reredos on either side to carry on the lines of the screens in the side arcades of the chancel. These wings were intended to be left in plain stone to correspond with the screens, and the result of the painting and gilding which has been applied to them has been to separate them too much from the walls of which they should have appeared to form a part. The work has been carried out by Messrs. H. H. MARTYN & Co., of Cheltenham, from the design of Mr. J. STANDEN ADKINS, of the firm of JAS. BROOKS, SON & ADKINS. It is intended to fill the arcades in base of reredos and in wings with panels of coloured marble presented as memorials. The first three sections of this work are being prepared by Messrs. DYKE & SON, of Highgate Road.

CHURCH OF ST. JOHN BAPTIST, HOLLAND ROAD, KENSINGTON.—REREDOS IN LADY CHAPEL.

THIS reredos, the benediction of which took place on Christmas Eve, has been executed by Messrs. H. H. MARTYN & Co., of Cheltenham, from the design of Mr. J. STANDEN ADKINS. The wall arcade shown on the south side, which has not yet been carried out, is intended to receive small marble memorial tablets, of which a considerable number have already been temporarily attached to the wall of the chapel.

PREMIATED DESIGN FOR PRIMITIVE METHODIST CHURCH AND HALL, CONSETT, DURHAM.

THE design published herewith was awarded first place out of thirty-five submitted for the above competition. The assessor in his report remarks that a number of the designs indicate considerable ability in planning and knowledge of the class of buildings required. Of the winning design, the assessor says:—"It will need some amendment to meet requirements, which I consider the author will be able to make within the limits of the stipulated cost." The successful architect is Mr. J. W. F. PHILLIPSON, Newcastle-on-Tyne.

DESIGN FOR A TOWN RESIDENCE.

THIS shows the detail of front entrance to a town house suitable for a professional man. The materials proposed to be used are red brick, with Portland stone dressings, together with wrought-iron railings.

THE PRESS AND ARCHITECTURE.*

(*Concluded from last week.*)

THE influence of environment upon the development of the community, as affecting not only its health, but its moral welfare, has received but scant attention in the daily Press, though the awakening knowledge of hygienic necessities has developed more interest in the matters of housing. Even now I suggest that so important a subject as this has not received the attention it demands. As evidence of this I would mention Mr. John Burns's Town-planning Bill, which seems to have been considered more from the point of view of making political capital than any other. Plenty has been written about the slums of our big towns and cities. Plenty has been written about our villages, but who has dealt adequately with our suburbs? I do not mean the suburbs with their detached or semi-detached residences nestling amid greenery and trim gardens, but the drab, gloomy, interminable streets of dull and sordid houses—all ground out of the same mill—with little to relieve the monotony of sooty bricks and mortar, save utilitarian lamp-posts and untidy back yards. Has it been realised what drab, gloomy and monotonous existences are led by the unfortunate individuals who are compelled to inhabit these grey and colourless vistas of miserable *monotony*? Has it been fully realised what effect this environment has upon the lives of these people? Is it saying too much to assert that if the Press had done its duty these acres of dreary monotony would have been an absolute impossibility?

Our cities and towns should have been girdled with garden cities. Our pretty suburbs should have been safe from ruin by the brick and mortar fiend, who devours all be told that the "masses" do not know and do not appreciate the difference, that they are content to drag along dull and sordid lives in dull and sordid surroundings. It may be so. But why? Because they have been bred in the atmosphere and have never known any other, because they have never been taught that there can be any other environment than the drabness they have been accustomed to. Teach them that their hard lives can be cheered and brightened by different surroundings; teach them what those new surroundings can be, and I will warrant the difference will be appreciated, and quickly, too.

Surely it is a matter of education, and the Press could raise its powerful voice to urge so necessary a reform. Why should our land be blotted and spoilt by ugly towns and villages for lack of the necessary teaching? We architects cannot do it for fear of the accusation of "touting" for work; but the great Press can and should. The Press has the power to mould public opinion for good towards the betterment of the community. It has done it before, and now that it has discovered that such beings as architects actually exist, and that there is such a thing as architecture as distinct from building, let it cease from jibing and deal with great issues. At present it is tempted to revile architects because speculative houses do not consist mainly of cupboards, or because a little lack of common-sense is responsible for burst water-pipes. Still, it is something to be thankful for that architects are credited with the control of these things. Hitherto the builder got the credit—or discredit. A daily paper recently published an article on cupboards, holding architects up to derision for their neglect in this particular. It was not a good article, and the criticism was unjust. We architects are not perfect, and no one is more aware of our failings than ourselves, and that is why we ask for criticism, for fair, well-judged criticism written by men competent to criticise. We suffer because we are compelled to look upon our work from our point of view only, and we want to see the other side. And that is why this paper should have been read by a Pressman. As an architect, I want to know my architectural faults, but I want to have them pointed out by those most affected by my failings, and not by my brothers in the profession.

things that are green and beautiful. Absolute lack of intelligence and consideration has governed the laying-out of innumerable estates, simply owing to the absence of any guiding authority. We study the people's health by hedging them around with innumerable sanitary and building regulations, and rightly so. But these regulations might actually have been framed to stifle the development of the beautiful which, I suggest, is as essential to the health of the community as the hygienic restrictions that have been more or less the outcome of public opinion. Curiously enough, two days after the foregoing was written, an article appeared in an evening paper dealing with this very drabness and dreariness of suburban life in these ill-laid-out estates, and emphasising the deadly monotony of the existence led by the inhabitants. The cause was attributed rather to the Englishman's inborn love of privacy, and the suggested remedy was towards a communal state of existence leavened with a dash of privacy. The idea is by no means a new one, and several serious attempts have been made to develop estates on the principle, but so far as I know with poor success. Possibly the crushing weight of the servant problem will lead to a revival of the idea, and in the future the clerk or artisan, and, for the matter of that, the workman, will live in a quadrangle of well-designed dwellings around a trim and well-kept garden, his food supplied from a common kitchen, and his washing done in a common laundry, and with a common room for his relaxation with his fellows, and maybe a crèche for his babies. I do not suggest the common dining hall, which will never succeed until the Englishman changes his nature.

Compare the vision with the maddening uniformity of the parallel streets, destitute of verdure, endless vistas of dreary dulness, the houses of the same deadly pattern with no outlook but bricks and mortar at the front, and bricks and mortar at the back over the rubbish heap of a back yard called by courtesy a garden—each house having less individuality than a numbered convict. What sort of race are we breeding in these howling brick-and-mortar wildernesses? Why has our great and powerful Press been dumb? I may

Now I turn to another phase, which I think has received no attention at all. It is wonderful to me that the Press has been so long in discovering the human nature in architecture—human nature as expressed in every feature, every moulding, every piece of timber, every worked stone. Does not the Press see the history written or unwritten in architecture? Has it not dreamt of the romance wrapped in every ancient building? Its view of architecture has generally been from a hard, matter of fact, bricks and mortar, money-grubbing, utilitarian point of view, tempered by occasional articles from unusually well-informed contributors who have drifted abroad, and dish up hashed epitomes of the guide-book with a flavouring of sentiment. Occasionally an English town, which has achieved temporary notoriety through some event, will have a maudlin outpouring over its picturesqueness. How rarely are we favoured with a really instructive and pleasantly attractive article that would create enthusiasm and bring out the human interest underlying the picturesqueness? Some of the best it has been my lot to read dealt with Bruges at the time of the great pageant a few years ago.

It is a pity that the pageant craze has not drawn more attention to the analogy between architecture and history. Would that our Press could see how history has written itself in architecture. A new vista would open, now narrowed to the belief that Cromwell and his Ironsides were responsible for all visible iconoclasm. And the unwritten history, if it could only be revealed! What a mine of interesting facts awaits those who will dig beneath the surface! And the romance of it all! What a storehouse of fascination for those who can tear the secrets and even the sermons from the grey stones. Why, I know a little church on our English coast nestling in the greenery of a coombe amid the downs, a quiet and charming spot, with no special architectural merit, but notable for its picturesqueness, and as being typically English. That is how it would appeal to the average Pressman. But what does it tell those who can read its history as they would read an open book? It tells of a sleeping village surprised by French raiders, of battle, murder and sudden death, of women and children taking refuge in the old church tower, of fire and a dreadful holocaust, and of the slow repairing of the loved building by an impoverished little community of survivors. What a tale could be woven round these facts—for facts they are without reasonable doubt.

If the Pressman wishes to make use of this material, to place it on record for all time, he must make haste, for the modernising spirit of the age is laying heavy hands upon the open pages which are being obliterated one by one so that none may read them, and the book, once closed, is closed for ever. I have wondered if ever a Pressman visits Westminster Abbey and views with astonishment the vast crowds who throng the great building, gazing with veneration and awe on the vast storehouse of history before their eyes, and gazing ignorantly for the most part because no one enlightens them, and guide-books are a weariness to the soul. It is not as if they did not want to know. They do, as many can testify, and the Press does not help them.

* A paper by Mr. A. Needham Wilson, read at the last meeting of the Architectural Association.

The pity of it! Well, I do not want to labour the point, and I admit readily that much of the sting of my criticism has been blunted by the awakening of the Press, and by one journal in particular, whose efforts in promoting a well-conducted competition met, I think, with due appreciation from the profession.

Again I disclaim any advocacy of advertisement for architects, merely pleading that since the eyes of the Press and public are opened the knowledge of the latter may be intelligently guided. I am only desirous that the efforts of the Press should be directed in the right way for the furtherance of an art so intimately associated with the life of the people, and the perfection of which both artistically and practically is essential to the well-being of the nation.

It is not as if we architects had stood still. We have made great efforts to advance our profession, and, I think, with success, for surely modern architecture never stood on so high a level as it does now. That being so, we can appeal with confidence to the great power of the Press to lead in the further advancement and development of our art in the public interest. We are prepared to collaborate. Then in due time we may see our land no longer seared and defiled with all the hideousness of bald utilitarianism, hardly regardful of the bodies, certainly not of the intellects of the people. We may see created a public opinion born of knowledge which will demand as a right that the lives of dwellers in houses may be brightened by an artistic atmosphere, produced unconsciously, and not as a result of forced effort. It is a brave ideal, which much misunderstood men have devoted their lives to, and mostly in vain, because they had not the support of the Press. But their example lives with us, and at last we can welcome the signs that the long looked for support will be forthcoming.

An architect's career is scarcely one to be envied. It is a severe struggle to most of us, and hitherto has been embittered by the indifference of the public. But the era of obloquy and oblivion seems to be passing away, and perhaps the mighty hand of the Press will lift us into the embarrassing splendour of full recognition, with weightier responsibilities for ourselves and our art. Let us take care how we use the opportunity, and let us set our house in order against that day, for with increasing knowledge comes increasing criticism, and we shall be judged by results. It will be our fault if we are weighed in the balance and found wanting.

Mr. EDWARD SALMON, of the *Saturday Review*, who proposed a vote of thanks to Mr. Wilson for his paper, said that as a Pressman he thought he ought to say that the treatise had been delivered to the wrong audience. It really seemed to him that the lecturer had been preaching to the converted, and it must have occurred to the meeting that the proper audience should have been composed of Pressmen. They were not however altogether unused to that sort of criticism. They had their art critics, political writers, legal writers and gossipers of high society, and whenever they met anyone who knew something about a particular subject under review it was perfectly certain they would be informed that the writer was all wrong. They had Mr. Wilson's high authority that the Press was well informed, "our otherwise excellent Press" were the words used, on all matters except architecture, and after hearing the paper he was convinced the Press knew absolutely nothing on that subject. He derived nevertheless some comfort, in spite of all the criticism, from the fact that Mr. Wilson had adduced his evidence of ignorance, not from daily or weekly papers, but from novels. The novelist was privileged in this respect, and could take liberties even with their lives and destinies, and if that liberty was denied him his profession was gone. The purpose of the paper, however, he took quite seriously, and agreed that something should be done to remove the abysmal ignorance which had been exposed, but the Press could only hope to accomplish such a task by having the assistance of experts, the architects themselves.

Mr. LOUIS AMBLER seconded the vote of thanks, and said Mr. Wilson had mentioned amongst other things that young architects were apt to seize on almost impossible opportunities for displaying their knowledge, or perhaps, in some cases the want of it by rushing into print and going in for what had been called wild cat schemes. An imaginary dome on St. Paul's or the Bank of England, with additions as a sky-scraper, had been referred to. As a matter of fact he knew of one such instance. A young architect with whom he was acquainted, and who was an assistant at the time, was approached by one of the editorial staff of a newspaper who wanted to write on the subject of the possibilities of showing how the utilitarian qualities of a certain building might be increased. The young architect was asked to make a drawing setting out the arrangement, and this he did, the drawing afterwards being paid for and published. He believed the Press could do much towards the enlightenment of the people in the need for artistic and healthy homes. Buildings should be regarded as works of art and described as such, and he hoped the paper would induce the Press to adopt that view and so help the architectural profession more than it had done in the past.

Mr. F. D. CLAPHAM attributed the indifference of the public and the Press in architectural matters to the spirit of commercialism which prevailed at the present time. Architecture was not popular, the profession was not recognised at all, and no interest was taken in a building until it was noised abroad that royalty was going to open it. They had heard that there were art critics, and he asked therefore why did they not criticise architecture? The Press, he thought, did not know quite what to make of architects as a profession, and to the ordinary everyday person the architect was looked upon as a sort of glorified plumber. That want of recognition was entirely due to the profession itself, which still had no status. Why was it that the painter and the sculptor should get all the credit in the Press for what they did on a building when the architect of it was not even mentioned?

Mr. A. E. MUNBY said there were two sides to the question of responsibility. He did not think the Press were entirely to blame for its attitude towards architecture, because architects themselves often differed in the sense of what was good and bad in their art. If there was this divergence of opinion among themselves it must necessarily be very difficult for the Press to adequately express any views. He thought the absence of registration had something to do with the lack of recognition, and until the profession was embodied by a status of that kind it would be very difficult for them to call attention to the want of appreciation of architecture as an art because of the enormous number of men who practised in an unauthorised way. When they had a consensus of opinion on the subject of registration general views on architecture could be formulated, and then the profession could intimate to the Press the merit they should look for in their work.

Mr. ALAN POTTER questioned whether the architectural societies were not to a great extent to blame for the lack of interest taken in architecture by the public in that they seemed to treat themselves as bodies existing entirely for the benefit of architects, and not for public benefit. What trouble was taken to bring their proceedings before the public or the Press?

The CHAIRMAN in some concluding remarks to the discussion said he did not think architects would be properly recognised until they were a closed profession. How could they expect it to be otherwise when they were not registered, and anyone could call himself an architect?

ARCHITECTURAL EDUCATION.

DR. HONEYMAN, in the course of a paper read at a meeting of the Architectural Section of the Royal Glasgow Philosophical Society recently, first referred to the works in Glasgow in the earlier half of last century, and also, more particularly, to those designed by architects who were in practice there when he commenced business himself more than fifty years ago. He submitted that they compared favourably with the work of their successors, although they had to depend for their professional training on the old-fashioned apprenticeship system, when masters still recognised the fact that an indenture imposed certain obligations on them as well as on their pupils. In those old days, although masters were comparatively few, apprentices were also scarce; now competent and conscientious masters were scarce and pupils were superabundant. There was no doubt that apprenticeship had outlived its day, and ought, along with premiums, to be abolished. It had become a mere farce, and, in offices where the staff was large, little better than an economical method of providing principal draughtsmen with fags; hence our concern about a substitute. He thought it would be difficult to improve on the course proposed by the Liverpool School of Architecture, or on that recommended by the Educational Board of the R.I.B.A. The Glasgow School of Architecture and several others had adopted similar courses of study, but the weak point, he thought, in the Liverpool scheme was the too intimate association of the school with the University. He thought

Digitized by Google

they could not expect Universities generally to amalgamate in such a manner with schools. He thought they should maintain their distinctive character and help in the scientific side of architectural education only. Glasgow has shown how this may be done by recognising the value of the teaching in the evening classes of the Technical College and allowing them to be taken into account pro tanto in their course for the B.Sc. degree. This, he thought, was about all we could expect. Universities should have nothing to do with art or anything which cannot be made a subject of examination on clearly defined and identical lines in the case of all co-operating Universities, so that their degrees may all be rightly regarded as of equal value. He thought that obligatory examinations were only required, up to a certain point, to prove the acquisition of those branches of science now deemed essential for an architect. At that point all would be on an equality, whether members of the Institute or not. The point he referred to was this: Having passed the intermediate examination, or what the Institute had agreed to accept as its equivalent, or having taken a University degree, from these no further evidence of fitness to practise should be required. Of course, it would remain for the Institute and other associations to impose any special conditions they pleased to qualify for admission to their membership, but he thought such requirement should partake more of a voluntary character than hitherto. Uniformity in art examinations would have a prejudicial effect. He thought it hardly possible to specify hard-and-fast rules for examinations in art subjects. In the Institute's final examination each candidate for membership should be left free to define the scope of his examination and encouraged to "profess" as much as he chose, so that the examiners should get, not a mere knowledge of his qualifications up to a certain point, but, it might be, a long way beyond any point they would, according to the usual course, have thought of prescribing. This, he thought, would stimulate emulation and impart elasticity to the final examinations. Speaking generally, his view was that a broad line of distinction should be drawn between the scientific and the artistic sides of the architectural student's education. He would advise that the Institute's Educational Board should define exactly to what point in the civil engineer's course the architectural student should go, and a universally applicable and rigid examination would then test his knowledge. But the test of his artistic ability should be somewhat variable and elastic. They would observe that his intention was to warn rather than to advise. All were probably at one in the opinion that architects in future should have more systematic scientific training than hitherto. Such training would only conduce to freedom in designing and would do no harm, although all had reached exactly the same standard. But we cannot speak of the same standard in art training in the same way. For example, if we suppose a hundred young men finishing their course in one of our excellent schools of architecture on equal terms, and the same number (having identical scientific attainments) finishing their course in the old-fashioned apprenticeship way, from which lot should we expect the best architecture? From the second lot, he had no hesitation in predicting. It might be objected that their taste might be warped by mannerisms. But would it be better to have a hundred architects with a hundred different mannerisms (which would be modified or obliterated according to individual idiosyncrasies), or, in the other case, only one mannerism, but that indelibly stamped on each of the hundred? The difficulties he had referred to in the way of returning to the old apprenticeship system were not insuperable. Nevertheless, the scholastic was destined to be the method of the future. He had no difficulty in predicting that this would result in the production of a great many superfluous architects and a corresponding increase in the intensity of the scramble for employment. What the effect on our twentieth-century architecture would be he must leave time to tell.

The Edinburgh Architectural Association have made the following changes in the Associate Section Prize Scheme:—Competition A 1: Design for a public hall for a country town. The handing-in day has been altered to March 15. First prize, 3*l.* 3*s.*; second prize, 1*l.* 1*s.* Competition A 2: Design for the terminations of the western towers of a large town church. The handing-in day has been altered to March 31. First prize, 2*l.* 2*s.*; second prize, 1*l.* 1*s.* Competitors are not now obliged to submit drawings for both designs. The handing-in day for apprentices' competition remains as before.

ART APPLIED TO DECORATION.*

THE impulse to decorate a useful object is one common to all mankind. It is merely to continue a little further the labour of simple manufacture. With this instinct is involved the equally natural impulse which drives men to imitate those objects about them by which they are chiefly interested. Decoration must not interfere with the utility of the object decorated, but must rather express, or at all events be conformable (in spirit as in shape) to that utility. As long as an object is only intended for use, it is not a work of art, though it may indeed be beautiful. Some of the world's best decorative art has been in the decoration of walls and ceilings. Raphael's best work is the wall colouring of a suite of apartments in the Vatican; many of his cartoons were made for tapestry. Michel Angelo's best work is the decoration of a ceiling in the Pope's private chapel; while Titian and Veronese put some of their best work on the outside of the walls of houses in Venice.

Very few architects or decorators give enough thought to colour or design. In the past there has been a great gulf between the architect and the decorator, but it is generally recognised now that the artist and the craftsman cannot rightly be parted from one another without serious injury to both. "Decoration" is the most natural expresion of an artist's feeling for his material, it is vitalised by the energy which is behind the tool, and is addressed to the senses of "seeing and feeling." It tells of a man's impressions, of his environments, of his susceptibility or dulness of nerve in the receiving and imparting of impressions of sense. Constructive design has a mission to fulfil, a purpose to serve apart from ornament. Ornament is a matter quite apart from constructive design, and is excusable and allowable only so far as it fulfils its own mission of being beautiful. This quality of beauty is again only to be considered in its suitability to the material from which it springs, to the place it is to occupy and the purpose it is intended for.

Applying these principles to our houses, &c., it may be said that as much as possible the windows of houses should be glazed in a style suitable to the architecture of the building or its surroundings. For instance, one often sees leaded glass panels of a very ornate design put into windows of houses that were built only about eighty to a hundred years ago, and large squares of glass put into so-called modern Queen Anne villas. It is a great pity that such mistakes should be made to-day by both architects and decorators.

This also applies to decoration. For instance, in an old house in Queen Anne's Gate, the interior of which has the original Adam ceilings, cornices, and friezes, the decorator who did up the house some few years ago thought it correct to cover the walls of the principal rooms above the surbase moulding with a raised Tynecastle paper, and covered the dado with a Japanese paper, and in most of the rooms removed all the good old marble mantelpieces and put wood ones of a very wooden un-Adamlike design instead. All the big London landlords should stop tenants removing valuable mantelpieces and making alterations and so-called improvements without their consent. In a house which is to let on one of the big London estates the late tenants removed a valuable mantelpiece and they propose allowing a sum of money to replace it.

Too much pattern is used by the ordinary architect or decorator, he overloads the ceilings and walls with pattern; then the upholsterer comes in and puts more pattern on the curtains; after that, the carpet man steps in with a big design for the carpet, and then the climax is reached when the lady of the house chooses her big flowery chintz loose covers. The result is a nightmare, no rest anywhere. If we have enriched or decorated ceilings and cornices, we should have plain or panelled walls; or if a simple ceiling and cornice, we should have a good frieze with a self-coloured wall under it, with curtains of a bold design and of a colour to harmonise with the walls, and a carpet almost if not quite plain, of the same tone as the curtains.

There is every reason to believe and hope that with the present reawakening of the handicrafts connected with our technical schools throughout Great Britain design and colouring will improve if design is properly taught, and that at some future date we shall have beautifully decorated houses; also that the art of decoration may not be despised by men of education and refinement, and that the public may understand and appreciate colour and design in its simplest and in its most elaborate forms, according to the possibilities and requirements of the particular style of house they occupy.

* Abstract of a paper entitled "Art Applied to Decoration," by Mr. W. Stewart-Greene, read before the Incorporated Institute of British Decorators at Painters' Hall, E.C.

Digitized by Google

With regard to wall-papers it may be mentioned that what is known as flock wall-paper was invented about 1634, and was probably used on the walls of the picture galleries at Hampton Court Palace in the reign of Charles I. There is little doubt that Chinese wall-papers were used in the time of Queen Anne. Some writers are of opinion that we copied the Chinese wall-papers about 150 years ago. In 1786 a Mr. Sherringham of London employed a number of artists, who turned out some very fine wall decorations. Machine-made papers are first mentioned as being made about 1837, but it was some years later, after much trouble and money had been expended, that they became a success, and to-day it is very wonderful what an effect can be produced. The sale of hand-printed wall-papers during the last few years has suffered through customers being able to get cheap machine-printed wall-papers.

In conclusion it may be asked what is art? Everybody from the big stores to the art student is talking about it, writing about it, and more or less interested in it, and it is sincerely to be hoped that we shall in the near future arrive at a solution of the problem.

THE TECHNOLOGY OF DECORATIVE AND PROTECTIVE PAINTS.

TWO well-attended lectures on the above subject were recently given by Mr. J. Cruickshank Smith, B.Sc., F.C.S., to the Architectural School of the Polytechnic, Regent Street.

The lecturer said that no words of his were necessary to impress the importance of paint from the standpoint of the architect and the property owner. It is obviously to the interest of the property owner that his property should be protected in an efficient and tasteful manner from the various destructive influences to which it is exposed, and it is plainly the business of his professional adviser, the architect, to be in a position to advise his client in the best manner as to the proper materials to use under given conditions.

A distinction is to be drawn between decorative and protective paints. The latter class, being used with the special object of protecting the surfaces on which they are applied, they have to be manufactured with the greatest care, and the choice of materials used in them is more limited than is the case when merely decorative paints are in question.

The Component Parts of Paints.

Speaking in the most general terms paint consists of two portions, a solid portion and a liquid portion. Each of these component parts is of great and equal importance and they must be considered together, as the finished paint owes its properties to the suitable adjustment of the solid and liquid portions. Linseed oil is looked upon as the base of the liquid portion of paints, and it is important to remember the great variations that are liable to exist in this material. The term linseed oil by no means carries with it any definite guarantee as to composition, except that the material so described is understood to be the unadulterated product of the seed of the flax plant. The great fault with much of the linseed oil used by painters is that it is far too new. There is an enormous difference between a new oil and a well-matured or tanked oil.

The pigmentary part of paints is now engaging the attention of scientific men in connection with the paint industry, and one point that has been thoroughly well proved is that the more finely ground a pigment is the better it will be for paintmaking purposes. This consideration has induced paint manufacturers to devote much thought to the improvement of their paint machinery. The extremely workman-like and efficient nature of the various machines and pieces of plant which now form part of the stock-in-trade of every well-equipped paint maker is worthy of all praise.

In order to appreciate the technology of paints it is well to fix attention in the first instance on the pigment itself. The characteristics looked for in a satisfactory paint pigment are opacity, absence of crystalline structure, chemical inertness, fine state of division, insolubility and the property of amalgamating readily with the vehicle. It is now understood that the causes and conditions which go to the making of a successful paint are not only chemical but physical; that is to say, it is not merely the chemical composition of the paint that determines its value, but also its physical and mechanical properties, these being due in great measure to the physical properties of the pigment contained in the paint.

Theoretically a film of protective paint should consist of a number of closely packed small spheres of equal size, in perfect equilibrium chemically and physically, embedded in a permanent cementing medium. This theoretical state of things has not yet been reached in practice. All that we can do is to endeavour to approach it as nearly as possible. The opacity of a paint depends both on the pigment and on the medium, and the opacity of certain pigments varies considerably, according to the medium in which they are placed. Thus, for example, ordinary whiting possesses a high opacity when suspended in a medium consisting of size and water, but a low opacity when suspended in linseed oil. White lead has a much higher opacity in turpentine than it has in linseed oil.

Destruction of paint films may be due to internal chemical action between the particles causing a change of bulk in the individual particles and thereby setting up strains and stresses inside the paint film. It is also due to internal changes caused by physical forces between the vehicle and the pigment, causing rearrangement of the particles. It may be due also to chemical decomposition of the pigment from outside sources, such as sulphurous gases in the air, &c. Destruction is also caused by chemical decomposition of the vehicle, whereby the latter becomes saponified or hydrolysed. Again, destruction may arise from moisture affecting the ground, the chief effect of the latter being rusting if the ground is iron or steel. So far as protective paints on iron are concerned, rusting is by far the most important cause of destruction, partly because it is so difficult to prevent it. The prime cause of rusting is moisture, and there are three sources from which this moisture may arise:—(1) It may be in the ground itself, iron being porous and absorptive of air and vapour; (2) it may exist in the paint; (3) it may come through the paint, and it has been proved that no paint film of which linseed oil is one of the chief constituents can be made thoroughly impervious to moisture.

The causes of the discoloration of paint are numerous, and a paint may become discoloured without being absolutely destroyed. In the case of white paints discoloration is frequently due to the linseed oil which they contain. Linseed oil always causes yellowness in paints. It is found that such discoloration is more apparent in cases where the paint has not been exposed to light.

The final lecture was devoted to a consideration of zinc paints, the lecturer describing in detail the leading classes of such paints and showing practical examples of work done with them. He also indicated the respective properties and merits of oxide of zinc and sulphide zinc white, concluding by giving suggestions as to the mixing and application of these materials.

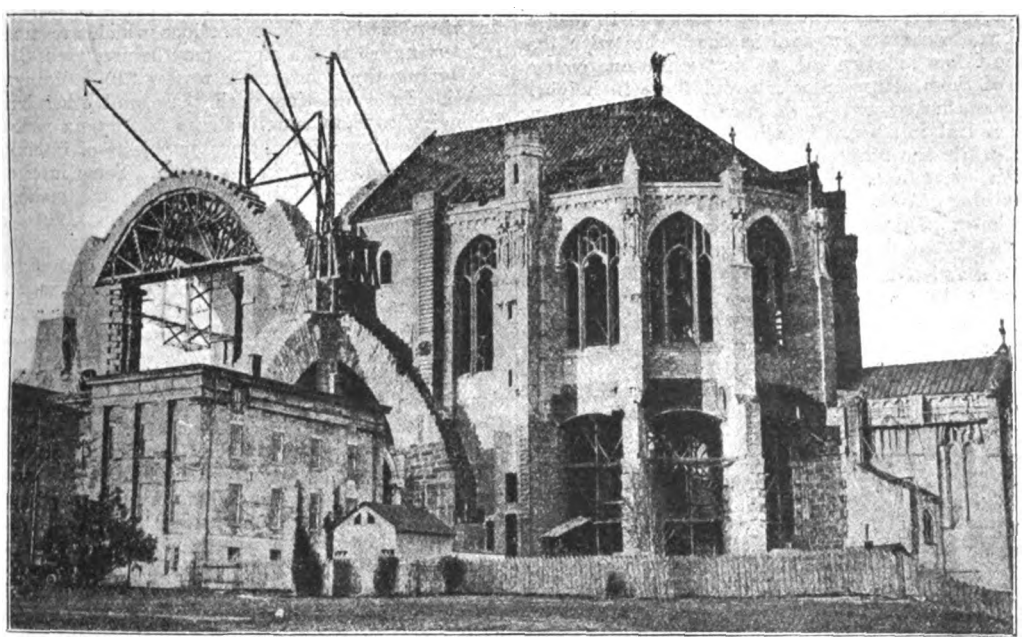
At the close of the course the principal of the Architectural School, Mr. Charles Mitchell, in proposing a vote of thanks to Mr. Cruickshank Smith, expressed the hope that next year he would be able to give them a longer and more complete course of lectures on the same or a similar subject.

ST. JOHN THE DIVINE, NEW YORK.

A DETAILED constructional account has been published by the *Engineering Record* showing the progress up to date of the new cathedral that is being erected in New York from the designs of Messrs. Heins & La Farge.

The cathedral of St. John the Divine, now under construction on Morningside Heights in New York City, will, when completed, be the fourth largest church in the world, being exceeded only by St. Peter's in Rome, and the cathedrals of Seville and Milan. It will be cruciform in plan, 520 feet long, 165 feet wide across the nave and aisles, 288 feet wide across the transepts, and will cover 99,500 square feet. The crowning detail will be an imposing central tower and spire, planted on a base 100 feet square, directly above the crossing, and rising to a height of 425 feet. Two smaller towers are located at the front of the building, and four in the angles formed by the intersection of the nave and transepts.

The cathedral occupies a commanding site on the crest of the heights, at a ground elevation of 124 feet above tide, overlooking a large part of New York City, the Borough of The Bronx, and Long Island. The plan is of the central area type, which affords, in the crossing, space for accommodating a large congregation close to the sanctuary. The architectural style is Romanesque, influenced by the Byzantine. The completed structure is estimated to cost $10,000,000. The corner-stone was laid in 1891 and work has been advanced as fast as funds, which come from volun-



Digitized by Google

tary contributions, have allowed, the progress in the last year being much greater than in any other similar period.

The most interesting structural features, so far as the work has progressed, are the four great arches, each with a clear space of 85½ feet and a rise of 57 feet 9 inches, which form a square of 97½ feet and carry the 425-foot tower, imposing a weight of 12,600,000 lbs. as the reaction of one arch upon the pier, and giving a total weight of 34,178,000 lbs. at the base of each of the four corner piers from which they spring. They are each 12 feet wide, 14 feet 3 inches thick at the springing line, and 12½ feet at the crown, and contain 1,180 cubic yards of granite masonry. The intrados is three-centred, with a radius of 62 feet 9 inches beginning at the springing line, succeeded by a radius of 73½ feet across the haunches, and a radius of 30 feet 9 inches at the crown. The springing line of the great arches, at elevation 198, is 74 feet above original ground level, and the intrados at the crown is at elevation 255 feet 9 inches or 131 feet 9 inches above the ground. Each of the main piers is 21 feet square and has bearing against it two flying buttresses, one for each of the great arches resting upon it. The buttresses have an average thickness of 12½ feet, are 13 feet 3 inches wide, and have a radius on the intrados of 43½ feet. The span is 21½ feet, the rise 37 feet, and they rest on piers 44 feet high. The great arches, piers, and flying buttresses, all of which are constructed of granite, will be concealed, when the cathedral is finished, either by the exterior architectural features or by an inside finishing of Frontenac, Minn., buff-coloured limestone, and by a ceiling dome, which will be supported by two small piers measuring 6½ feet by 12 feet 3 inches and 102 feet 9 inches high above ground level, adjacent to each of the main piers.

The easterly great arch, marking the eastern boundary of the crossing and the beginning of the choir, and the lower parts of the westerly main piers and those adjacent to them, were finished in 1900. The construction of the upper parts of the westerly piers was taken up in August, 1907, and since then not only the piers, but the three remaining great arches have been finished. The methods and centres employed differ greatly from those used in erecting the easterly arch. In that case the derricks for placing the voussoirs were seated during the early part of the work on one of the small piers, adjacent to each main pier, and later were transferred to the tops of the main piers to finish the work. The arch centres were of very heavy construction, consisting of segmental trusses, one on each side of the crown, supported by a post carried on an A-frame. The flying buttresses for taking the thrust of this arch were not constructed at the same time as the arch, and therefore the centres were left in until the present construction season, when the buttresses were built and the centres cut out, the latter operation proving so difficult that two weeks were required for the work. As in the case of the centres for the later work, they rested upon the tops of the small piers adjacent to the main piers, and were used for only the upper part of the arch, the skewback portion, for a height of 28 feet 9 inches, being laid against brick spandrel walls built on short arches between the small and main piers.

In carrying on the present work instead of placing a derrick upon each pier a tall timber tower was located in the crossing and supported two stiff-leg derricks, which, without being shifted, were able to build the upper parts of the piers and all three arches. A tower of the desired construction had previously been used in building the choir, and since it was no longer needed in that position, was jacked up, placed on rollers and hauled out into the crossing where, after being revolved through a horizontal angle of 45 degrees, it was seated on a 25-foot base of similar construction previously prepared for it. The tower was 30 feet square, about 143 feet high from the derrick bases to the floor of the crypt, on which it rested, and was built with 12 by 12-inch posts, 15 feet apart on all sides, and braced with horizontal and X-bracing of 3 by 14-inch timbers. Interior bracing was built between opposite sides passing through the centre of the tower, thus dividing it into bays, 15 feet square in plan. One corner was opposite the crown of each arch, so that the sides were at an angle of 45 degrees with the planes of the arches. Upon the corners near the northerly and southerly arches derricks, with 63-foot masts and 74-foot booms, were located. They were operated by 8 by 10-inch Lidgerwood double-drum hoisting engines, located at original ground level, 100 feet north of the nearest corner of the tower.

VIEW SHOWING ARCH CENTERING AND ONE ARCH RING IN PLACE.

The skewback portions of the great arches were built up to the tops of the small piers against brick spandrel walls. Timber centres were then set upon the small piers, for supporting the haunches and crown. Four centering trusses, spaced 3 feet apart, were required to carry one arch. In general, it took two days to raise the trusses from the ground to their position, place the transverse bracing, and wedge up to proper elevation. The same length of time was also required to remove them after the arches had been completed. Only one set of centering was used for the three arches, work being carried on with only one arch at a time. The complete centering for one arch, including the four trusses and the transverse bracing, contained a total of 23,500 feet b. m. of lumber and 8,500 lbs. of bolts and washers.

The centering trusses were built at the base of the timber tower in the crossing, and two of them were connected with timber battens and hoisted to place by two sets of falls, one set being attached to the centre of each 8 by 12-inch batten. A pair of these trusses thus connected was able to stand without lateral support if the wind did

Digitized by Google

not exceed 20 miles per hour. After the four trusses were in position the transverse bracing was placed, the trusses meanwhile being tied together transversely. The bracing consists of pairs of 4 by 6-inch yellow pine horizontal and diagonal members.

The wedges inserted under the supports for dropping the trusses preparatory to removing them from beneath the completed arch are quite simple. The wedge is drawn up against an upper and a lower bevelled block by 1-inch bolts which have threaded ends 6 inches long. Four ¾-inch bolts are passed through both the wedge and bevelled blocks and bear against 4 by 6-inch blocks on each side. When it is desired to drop the centres, the ¾-inch bolts are removed, the nuts on the 1-inch bolts holding the wedge slacked up about ¼ inch and started by striking them with a maul. This is continued until the wedges have moved out 4 inches, when the ¾-inch bolts are replaced in the other set of holes in the upper and lower blocks. The centering will then have dropped 2½ inches vertically, which is enough to allow them to be moved sideways on pipe rollers and taken out. The material of which the trusses are made is yellow pine throughout except for the battens, which are white oak.

The staging hanging from the trusses extends about 24 feet below the bottom chord and was constructed for marking the centres of the radial joints. Wires were attached at the centre points and when stretched through the proper point for the voussoir, as marked on the lagging, gave the proper direction for the joint.

The granite voussoirs are cut to 4 by 6 feet and 20 inches thick and alternate courses are laid in the arches with the 4-foot and the 6-foot sides radial, so that while one course contains two of these stones in width and three in height, the two adjacent courses contain three in width and two in height. The radial joints are 1 inch thick and filled with 1:2½ mortar, while the other joints are 4 inches thick and are filled with concrete made in proportions of 1 : 2½ : 5, the aggregate being gravel. Giant Portland cement has been used. The lower ring is first built completely over the entire arch and keyed, before beginning the top ring. In order to insure the exact placing of all the stones the position of each voussoir was painted on the centering by the engineer in charge and with these marks and the centres for the radial joints as guides all three arches closed without any variation.

Since the buttresses on the westerly main piers have not been built at present, the thrust of the three arches built during the past year is taken in each case by six 2⅝-inch rods which take bearing on 12-inch channels on the back of the masonry. These rods have been placed at the level of the tops of the small piers, 28 feet 9 inches above the springing line.

The floors, domes and roof are built entirely with flat tiles about 1 to 1¼ inch thick, laid in Portland cement mortar, without any structural steel whatever, except where skylights are inserted in the roof. The tiles vary in length from 12 to 18 inches, and are about 6 inches wide. No matter where used the construction always consists of arches, and since the weight of a couple of courses, which quickly become self-supporting, is small, the centering required is extremely light, consisting in ordinary cases of a couple of 1-inch boards placed on edge and trussed lightly to hold the arch form.

The floor of the choir, forming the ceiling of the crypt, is composed mainly of a series of large vaults of about 56-feet span divided into ribs and domes springing from supporting granite piers spaced 20 feet, and in some instances 25 feet, on centres. The ribs are composed of from ten to fifteen courses of tile and the domes springing from them are usually four layers in thickness. In order to bring this vaulting to a level floor, light cross walls have been erected on the haunches and upon these counter arches two courses in thickness have been built. The ambulatory floor running around the choir is likewise composed of ribs and domes, springing from the inner to the outer line of piers. The choir floor directly under the altar terminates in a half-dome. Owing to the heavy loading expected on this floor, which served temporarily as a platform for the various building trades engaged on the structure, particularly for derricks for hoisting the stone work during erection, it was built for a safe load of 400 lb. per square foot. The first crypt vaulting was constructed about 1899, and the crypt has been used ever since as a temporary place of worship.

The ceiling of the choir was built during the last construction season, is about 125 feet above the floor, and varies in span from 50 to 55 feet. Over the sanctuary the form is that of a half-dome and the choir portion is in the shape of Gothic vaulting, with intersecting ribs. The filling is of tiles, laid herringbone for a finished soffit. The portion over the sanctuary will be decorated with elaborate mosaic.

The domes which form the ceiling of the choir are considerably below the main hipped roof, which is also of tile construction, carried by large main supporting ribs of about 60-feet span. Between these are sprung a series of secondary ribs upon which the masonry roof rests, the latter composed of three layers of tile, the outer one being of porous material, so that the copper roofing can be nailed directly to it. The main supporting roof ribs are about 4 feet wide, 2½ feet thick, and are of cellular cross-section.

The entire ceiling and roof construction necessitated only the usual bricklayers' light staging, built parallel with the walls at a distance of about 10 feet, and from this brackets or cantilevers were thrown out until they arched over the interior, thus obviating the necessity of any heavy timber work or centreing, which would have been required had brick, stone or concrete been employed.

HISTORICAL BUILDINGS IN LONDON.

IN connection with street improvements and other works, says the local government committee of the London County Council, the Council frequently acquires premises with a view to demolition. These premises sometimes possess noteworthy architectural features or are historically interesting, and photographs are taken of such premises, or drawings made of those portions which are architecturally interesting, so that a record may be preserved.

During the year under review 210 buildings were surveyed. In connection with these and other buildings not belonging to the Council, sheets of fifty-six measured drawings of portions of buildings or objects of interest were prepared and 165 photographs taken. Some interesting pieces of carving were obtained, including the mahogany balustrading of a staircase with carved brackets, fluted newels and spiral balusters, carved oak and deal door trusses, lead rain water heads, stone date tablets, coins and mediæval tiles. H.M. Office of Works gave permission for surveys to be made on the site of the New Post Office buildings in Newgate Street, where, as a result of excavations, remains of the old City wall and other rubble walls were being exposed.

Consideration is also given to such cases of alteration or demolition by private owners or authorities other than the Council of buildings in London of historic or architectural interest as are brought to the Council's notice. The district surveyors under the London Building Acts have been requested to notify the Council whenever it is brought to their notice that buildings possessing interesting architectural features or historical associations are about to be demolished or substantially altered. For purposes of record, photographs are taken and drawings made of the buildings and objects of interest therein. The owners of buildings about to be demolished usually allow the Council's officers access to the premises to enable records to be made, and assistance is rendered by other persons supplying to the Council copies of drawings and photographs of buildings of architectural interest. Through the notification of the district surveyor, particulars were obtained of certain chalk and rubble wall remains in the City of London, and a few examples of Samian pottery were also secured.

Crosby Hall, Barnard's Inn, Battersea Riso House, Ely House, Eltham Palace and the Ironmongers' Almshouses, Kingsland Road, were the chief buildings surveyed during the year and of which records were obtained.

Crosby Hall.

Early in the summer of 1907 it became known that Crosby Hall, Bishopsgate, had been sold to the Chartered Bank of India, Australia and China, which proposed to pull down the building and to erect bank premises on the site.

On July 2, 1907, the matter was brought before the Council by the committee, who in their report mentioned the principal historical associations connected with Crosby Hall. The hall was erected in the fifteenth century by Sir John Crosby, an eminent City merchant, and among notable persons who resided there were Richard, Duke of Gloucester, afterwards Richard III., and Sir Thomas More; and the building was the recognised scene of one of the most famous incidents in Shakespeare's drama of "Richard III." The hall was saved from destruction in 1832 and restored by means of public subscriptions.

A letter was received from His Majesty the King expressing the hope that means might be found to preserve the historic building.

Digitized by Google

In October 1907 a scheme was approved at a public meeting at the Mansion House, by which it was proposed that an alternative site in Bishopsgate Street, contiguous to the property acquired by the bank, should be offered in exchange for Crosby Hall and a small additional site adjoining, and a committee was appointed to raise funds and to carry out the scheme, estimated to cost 150,000*l*. The Council, on October 22, 1907, agreed to contribute 1,000*l*. to the fund, and the City Corporation promised a similar contribution. In the following month, however, it was announced that although about 50,000*l*. had been subscribed to the fund, the bank directors would not allow further time for proceeding with the scheme unless the Corporation or some other responsible body guaranteed that the scheme would be carried through and the substituted site transferred to the bank without any payment by the bank.

On the failure of the negotiations of the preservation committee, the committee brought the subject again before the Council, which on December 17, 1907, authorised the committee to ascertain whether the City Corporation would co-operate with the Council in securing the site of Crosby Hall, and whether the subscribers to the preservation fund would transfer their subscriptions to the Council in order to assist in saving the building, subject to the scheme not entailing any charge on the county rate. Negotiations were thereupon entered into with the bank directors and the several bodies concerned, as well as with the Board of Trade, which had expressed its willingness to consider a proposal that the Commercial Intelligence Branch of the Board should be housed in Crosby Hall and the immediate vicinity.

Several schemes were outlined and discussed with the officials of the Government departments concerned and at conferences at the Mansion House at which the Council was represented. All these schemes presented financial difficulties and were further complicated by the fact that, having regard to the proposed public user of the hall, the Office of Works regarded less than one-fourth of the superficial area of the hall as effective for Government purposes. Additional accommodation had therefore to be sought elsewhere, thus increasing the financial burden. None of the schemes involved less than an expenditure of 100,000*l*., after deducting the sum collected as the result of public subscription, which would have required the net rental to be about 5,000*l*. a year, whilst the officials of the Office of Works would not recommend concurrence in a scheme involving payment of a rent calculated on other than a commercial basis; that is to say, they would not have any regard to the special interest attaching to the building. An appeal was made to the Government, and on January 27, 1908, a deputation, headed by the Lord Mayor and consisting of members of the Council, the City Corporation and other bodies interested, waited upon the First Commissioner of Works, who, however, stated that he could not see his way to recommend the additional expenditure required for the purpose of housing the Board of Trade at Crosby Hall, and that he could not, as suggested by the deputation, advise the Government to make a contribution for the acquisition of the hall under the Ancient Monuments Acts, especially as there was no precedent for the Government acquiring by purchase monuments of historic interest. The bank directors would not consent to further delay to allow of any fresh proposals being put forward.

In reporting to the Council on February 4, 1908, as to the efforts made to save the hall the committee drew attention to the insuperable difficulties met with. The bank directors were not prepared to use Crosby Hall for their own purposes nor to surrender it unless provided with a site which, in their opinion, was equally convenient. The only site which would be accepted in exchange for the Crosby Hall site was a larger and more important one, and as a cleared site its value was double that of the site of Crosby Hall. The large expenditure needed to purchase this alternative site financially crippled the preservation scheme.

The directors of the bank were good enough to make arrangements for the preservation and storage of the fabric of the hall, and at the close of the year the committee were considering whether the Council should take any action in regard thereto.

Ancient Monuments Acts, 1882 and 1900.

The efforts made to save Crosby Hall having shown that the existing statutory provisions relating to the protection of monuments and buildings of historical and architectural interest were inadequate, the committee considered whether steps should be taken to extend the provisions of the Ancient Monuments Acts, 1882 and 1900, with a view to preventing the demolition of buildings of a similar character. In France a schedule is kept of all monuments and buildings deemed worthy of preservation, with the result that no such monument or building can be destroyed, even in part, without the consent of the Government.

A Royal Commission was appointed during the year to make an inventory of the ancient and historical monuments and constructions in Scotland and to specify those which seemed worthy of preservation, and on the recommendation of the committee, the Council on March 31, 1908, decided to approach His Majesty's Government, with a view to the inquiries of the Royal Commission being extended to, or a similar inquiry being undertaken in respect of, England and Wales.

No. 17 Fleet Street, E.C.

On April 3, 1900, the Council decided to acquire, restore and preserve No. 17 Fleet Street. This building was erected in 1610, and covered the site previously occupied by a building known as the "Prince's Arms." At least as early as 1617 the council chamber of the Duchy of Cornwall was located in Fleet Street, and this fact, combined with the title of the house and the design referring to Henry Prince of Wales in the centre of the ceiling in the front room on the first floor, tends to make it probable that this room was used as the council chamber.

During the building works, which were considerably delayed owing to legal difficulties, it was found that behind the façade visible from Fleet Street stood the original half-timbered front, with portions of the essential features intact. These included six fine carved solid oak storey posts and jamb mouldings of the bay windows, the storey beams and carved storey bracket, and portions of cornice mouldings. The ceiling of the room on the first floor is an excellent example of Jacobean enriched plaster work, and is unique in design. The ceiling was taken down in sections, and cleaned and strengthened under the supervision of Sir Caspar Purdon Clarke, C.I.E., C.V.O. The oak panelling with pilasters and cornice on the west wall of the room on the first floor belonged to the original building. The fir panelling on the east and south walls is eighteenth-century work, and includes a mantelpiece with some good carving. The staircase from the first to the third floor is also a good specimen of work of the same period. The stone archway leading to Inner Temple Lane has been rebuilt on the new frontage line, and the Society of the Inner Temple have rebuilt the southern arch in stone to accord with that in the front.

The net capital cost of acquiring the premises and the cost of the works up to March 31, 1908, was 24,860*l*. 10*s*. 4*d*. This involves an annual charge of about 1,246*l*., decreasing as the debt is paid off. The premises are let on lease for twenty-one years at a rental of 600*l*. a year, so that the charge will disappear by the forty-seventh year.

Mr. C. Y. Sturge, a member of the Council, was good enough to insert appropriate stained-glass panels in the windows of the room on the first floor, which, as it was associated with Henry Stuart, Prince of Wales, son of James I., has been named "Prince Henry's Room." Mr. Sturge has from time to time presented for placing in the room engravings of old buildings existing or formerly existing in the vicinity.

Prince Henry's room was opened to the public on July 26, 1906, and may be visited on week-days (except Good Friday and Christmas Day) between the hours of 10 A.M. and 4 P.M. from October 1 to March 31, and from 10 A.M. to 5 P.M. from April 1 to September 30 in each year. During the year ended July 25, 1907, 5,155 persons visited the room. When the room is not open to the public, it is available for the purposes of meetings.

LIVERPOOL CATHEDRAL.

AT the annual meeting on Tuesday the Liverpool Cathedral committee reported that they had received over 306,000*l*. towards the erection of the new building to complete the work in hand, in addition to 10,000*l*. raised by the Masonic Order for the chapter-house in memory of the late Lord Lathom.

In recording the progress of the building operations, the committee state that the walls of the choir have been advanced on an average 12 feet, and now stand at 40 feet above the floor. The lantern piers and arcade piers now stand 29 feet above the floor, and the four tower piers which are under construction are 23 and 25 feet in height. Some modifications have been introduced in the design of the choir, which the committee consider will add dignity and grandeur. The east window will be of large size, and in harmony with the general proportions of the building. The

Digitized by Google

walls of the lady chapel have been completed, and stand 58 feet above the floor, and the stone vaulting has been recently commenced. The order for the stained-glass windows in the lady chapel has been placed with Messrs. James Powell & Son, of Whitefriars, London. The committee invited competitive designs. The Earle family have made further contributions towards the cost of the construction of the organ, which relieves the committee of any financial responsibility. The committee have decided that the chapter-house to be erected by the Freemasons as a memorial of their late Provincial Grand Master, the Earl of Lathom, shall be representative of that body, and the architect, Mr. Scott, is now preparing a design to give effect to their decision. "The funds at present available," the report concluded, "are not sufficient to complete the choir. Further contributions to the extent of about 70,000*l.* are necessary, and the committee are very anxious that this sum should be raised, as it will not only enable them to complete the choir for divine service, but it will place them in a position to take over the property which has been set apart for the endowment of the Chapter, and thus give the diocese the advantage of a fully equipped cathedral and an endowed Chapter."

Correspondence

Illustrations in "The Architect."

Sir,—In common, I doubt not, with many of the readers of your valuable journal, I beg to express my disappointment that you have now discontinued, during this year, the issue of any more of the Cathedral series illustrations, which have been such an interesting feature in the publication for many years past. I think I saw a notice that you were intending to give some supplementary ones of certain of the earlier cathedrals which were not very fully illustrated, such as you have given lately of Southwell Cathedral. I do hope that you will still complete, in the same way, illustrations of some of the buildings which deserve a fuller treatment. May I also ask whether the College series of illustrations is not to be continued?

Thanking you for the great pleasure these beautiful photographic views of our grand historic buildings have given me, in common with hundreds of others,—I am, Sir, yours very truly,

James Sibree,
Missionary Architect in Madagascar.

Bromley, Kent: March 2, 1909.

[We certainly hope to publish some further Cathedral views. The College series will be continued.—Ed.]

Sir,—I hope you have not terminated the illustrations of British colleges, of which the last that I have seen was of Wadham on October 30 last. I am looking forward to binding these views, and I shall be very sorry if they have come to an end.—Yours very truly,

Robert Gladstone.

Woolton Vale, Liverpool: March 1, 1909.

[We published two views of Wadham in November; the next college will be published in April.—Ed.]

Poor Law Commission and Architects.

Sir,—It is a most injurious statement in the report just issued, placing on architects the onus of the increased expenditure on Poor Law institutions, and it is none the less injurious in that it is inserted as a careless passing suggestion, and not as a direct and definite charge. Of course, architects like to produce buildings that will do them credit; but it is in the hands of the building committees and the boards to prevent unnecessary expenditure on architects' schemes. The general public treats members of our profession as though our sole object is to "make money—honestly if we can, but anyway make it." A more callous, uncalled for, and iniquitous charge against a generally honourable body of men is not to be conceived.

And this charge, as more than shadowed forth in the Poor Law Report, is one that is made also both covertly and openly by individual clients *to*, though not of necessity *against*, individual architects, and is often made without conveying any sense of justified reproach or censure, which, to my mind, only increases the evil.

Cannot the Royal Institute of British Architects take up the question and make a public protest?—I am, Sir, faithfully yours,

March 3, 1909. A London Architect.

GENERAL.

The Wood Green District Council have decided to instruct the health committee to consider the question of providing public baths for Wood Green, with a view to inviting competitive designs from architects.

The Blackpool General Purposes Committee have given their assent to the proposal to include accommodation for a museum in the new building, to cost 2,000*l.*, which Messrs. Grundy have promised to give to Blackpool for the purposes of an art gallery. Messrs. A. Cullen, Lochhead & Brown, Hamilton, near Glasgow, the architects for the library, are to be instructed to prepare the necessary plans for the new building, which will be erected alongside.

Major Lewis Henry Isaacs, of Verulam Buildings, Gray's Inn, W.C., architect and surveyor, for forty-two years surveyor to the Holborn Board of Works, who died on October 17, aged seventy-eight, left estate of the gross value of 49,627*l.* 7*s.* 4*d.*, of which the net personalty has been sworn at 40,993*l.* 18*s.*

Hogarth House, Chiswick, has been offered to the Middlesex County Council in trust for the public by Lieut.-Col. R. Shipway, who saved the house from demolition some seven years ago. During the past three years it has been thrown open for inspection on three days a week. The offer is under consideration.

Professional Circles in India are somewhat exercised over the rather peculiar proceedings of the Calcutta Corporation. Having abolished the post of architect to the Corporation on the pretence of economy, it immediately invented other posts which swallowed up the economy, and now proposes to appoint an arboricultural adviser. It is difficult for our colleagues in India to understand that a city like Calcutta needs an arboricultural adviser but not an architect, and we share with and sympathise in their mystification. We trust that the recent movement here in favour of afforestation will not lead our embarrassed Chancellor of the Exchequer to decree the abolition of the posts of architect to the Board of Education and the Local Government Board.

The Design of Mr. William Bakewell, F.R.I.B.A., architect, of Leeds, has been selected in a competition for new premises at Leeds by the directors of the Pearl Life Assurance Company, acting upon the advice of their consulting architect, Mr. Percy Monckton, F.R.I.B.A., F.S.I.

The Royal Institute of British Architects held a special general meeting on Monday, when it was formally resolved that, subject to His Majesty's sanction, the Royal Gold Medal be presented this year to Dr. Arthur John Evans. At the subsequent business meeting three Fellows and forty-four Associates were elected, as well as M. A. Delpy, of Brussels, and M. Charles Louis Girault, of Paris, as hon. corresponding members.

The Architects' Benevolent Society will hold the annual general meeting in the rooms of the R.I.B.A., 9 Conduit Street, on the 9th inst. Mr. Ernest George, the president, will take the chair.

The Competition for plans of new Wesleyan church, schools and other premises at Lynton has resulted as follows:—(1) Messrs. Latrobe & Weston, F.R.I.B.A., 44 Corn Street, Bristol; (2) Alec W. Percival, P.A.S.I., 12 George Street, Plymouth; (3) Allen T. Hussell, F.R.I.B.A., Market Square, Ilfracombe.

A Quarterly General Meeting of the Glasgow Institute of Architects was held on February 17 within the secretary's chambers, 115 St. Vincent Street, Mr. John B. Wilson, A.R.I.B.A., vice-president, in the chair. Messrs. Hamilton Neil, 65 Kilbowie Road, Clydebank, and Alexander Neilson Knox, 144 Bath Street, Glasgow, were unanimously elected Fellows of the Institute. It was reported that Messrs. Vernon Constable, 38 Cornhill Street, Springburn, and Alexander David Hyslop, 124 St. Vincent Street, Glasgow, had been elected associate members. The secretary submitted a report on the matters which had been dealt with since last meeting. The associate members committee had awarded the prizes for summer sketches as follows:—First prize, 2*l.* 2*s.*, to E. G. Wyllie; second prize, 1*l.* 1*s.*, to A. Robertson. The Alexander Thomson Memorial Studentship, value 60*l.*, had been awarded to Mr. David Robertson, 2 Croft Road, Cambuslang, and the second prize of 20*l.* to Alexander Thomson Scott, High School, Stirling. Six sets of drawings were submitted, and the standard reached, especially in draughtsmanship, was higher than in any of the previous competitions. A selection of the R.I.B.A. prize drawings would be received for exhibition about the beginning of April next. Attention was called to the unsatisfactory nature of conditions of the Hutcheson's hospital competition, and it was remitted to the committee on public architecture and competitions to take action in the matter.

The Architect.

THE WEEK.

ARCHITECTS not infrequently have to superintend the erection of buildings, the construction of which necessitates the use of cofferdams to temporarily keep out water from the works, or the provision of retaining-walls to do so permanently. Therefore the sad disaster at Birkenhead Docks is not without concern to us, and may serve to remind us of two important facts that should always be borne in mind when we have to deal with waterside buildings. The first of these is that it must not be assumed that the water is quiescent, that the pressure which the cofferdam or the retaining-wall has to resist is merely that of so many feet head of water. It was not, in our opinion, the fact that the cofferdam that failed was 40 feet high, or that it had to resist the pressure of the huge body of water in the 59 acres of the East Float that caused the collapse, but the unusual circumstance that under the pressure of a strong wind the water of the East Float was in motion, and this the swaying motion that is set up by wave movement in a confined area. If the water had been quiescent it would not matter whether there were fifty-nine or a thousand and fifty-nine acres of water kept out by the cofferdam but when the body of water is swaying its volume tells. It should always be remembered, therefore, that water may be set in motion, and particularly in tidal water that not only the ordinary rise of tide has to be taken into consideration, but when wind is against tide wave-motion of an intense character is set up. It appears from the statement of DAVID JONES, the crane driver, "The water must have got under the timber supports and forced them away," that the second point on which we wish to comment may possibly have been a factor in the Birkenhead catastrophe. This is that in waterside building it should always be presumed, and will almost invariably be the fact, that the water is not only at the side of the building but below it, and if the water is tidal, there will be tidal action beneath, so that when, as frequently is necessary, basements below the high-water level are constructed, their floors must be strong enough to resist the blowing-up effect of the pressure due to the head of the high-water level. The tidal action of the Thames, for example, extends, we know, to quite half a mile from its present channel.

"ALL over the world every kind of man has had for the high places of his country or for the high places he has seen in travel (though these last have made upon him a lesser impression) a sentiment closely allied to religion, and difficult to fit in exactly with common words." "It is to be noticed that where men cannot satisfy this emotion by the spectacle of distant hills, or by the presence of nearer ones which they can climb upon occasion, they remedy the defect either in their architecture or with their trees." Thus Mr. HILAIRE BELLOC, M.P., in his weekly column in the *Morning Post*. And he illustrates his view by reference to examples of high buildings in low lands, Beauvais, Flanders, Strasburg, Salisbury, Chichester, Bordeaux. These are certainly cases in point, and we might add "Boston Stump," and the other instances amongst the churches of Lincolnshire and the Nene Valley. But Mr. BELLOC goes on to state the converse proposition, that in the neighbourhood of mountains or hills, buildings are low, that there is "hardly ever a building of the plains in the mountains." Yet it occurs to us that some of the notable buildings of the world are set on a hill, the Parthenon, Laon Cathedral, Mont St. Michel. Perhaps Mr. BELLOC would say that these simply emphasised his original proposition, and being more or less isolated, hills are crowned with architecture's effort to enforce and intensify the provision of nature. We may grant that the village churches of the Pyrenees or the Sussex Downs appear to bear out Mr. BELLOC's theory, but if we take the churches of East Anglia as supporting his view, how are we to consider the towers of Somersetshire? This is a fairly hilly district for England, that is, and if we want something on a larger scale we may look at Auvergne, where the churches are not what we should call low and modest in height, and the configuration of the country is sufficiently mountainous. Probably the presence of wealth, industry, and large communities in the plains, of poverty and sparse population in the mountains have had much influence on the character of buildings in past ages, though we may admit it as æsthetically right that it is unwise to attempt lofty structures when they are dwarfed by a background of nature's uplifting, even if it is allowable to crown a peak when the opportunity offers.

POLITICS in general are outside our range, but Mr. BIRRELL has made special reference to the building trade in his advocacy of Free Trade, instancing in particular the import of cheap doors from Norway and Canada. He stated that we "did not pay for those doors in gold." But that is exactly what we do. The English builder who buys a cheap foreign door does not pay the Norwegian with granite or brick, but with gold, or at least a bill or some other form of promise to pay gold. When the Norwegian has got the money, he is under no compulsion to spend it on buying cotton or woollen goods from England, he can buy from his own protected fellow countrymen. Even if he did buy from England it is no consolation to the joiner who is out of a job. It is no consolation to the architect that with the help of Norwegian doors he can build a cheap house if the joiner, out of employment, cannot pay the rent even of a cheap house. True, if the joiner were the only sufferer and everyone else flourishing because doors were cheap we might send round the hat and pension the joiner. But all manufacturing trades are suffering, and the goods we send abroad do not pay for the goods that we import. Our imports for the first two months of this year were of the value of 103,979,556*l.*, and our exports 56,827,498*l.* Can anyone believe that our exports paid for the imports, and that the foreigners were such bad men of business that they allowed us to make 47 millions profit on the 56 millions worth of goods we sent them? The effect of the trend of international trade upon architecture is, we think, to be found in a comparison of the imports of raw material with the exports of manufactured goods. Taking in each case the first two months of the year we learn that in 1907 we imported raw material valued at 50 millions, and exported manufactures valued at 55 millions, or a profit of 5 millions; in 1909 the raw material imported stands at 44 millions, and the manufactures exported at 45 millions, thus there is less profit to be spent on bricks and mortar.

INTERESTING as are the particulars that Dr. M. A. STEIN gave at the Royal Geographical Society last Monday of his explorations in Central Asia, we shall have still to wait some time before the full importance of his discoveries is before us, as he estimates that the mere unpacking and first arrangement of the archæological objects he has brought away will probably not be completed before July. One interesting ethnographical fact he appears to have established is that the ancestors of ATTILA and his Huns were the Hsiong-nu, against whom were erected the defences discovered by Dr. STEIN of the western extension of the empire of China afterwards abandoned.

OUR friends in France are paying us the flattering tribute of imitation by the Bill deposited in the Chamber of Deputies by M. CRUPPI, Minister of Commerce, modifying the French patent law so as to enact that French patents must be worked in France under penalty of forfeiture, in the case of new patents within three years, and in the case of existing patents within a time fixed by the Courts. A similar provision is proposed with respect to the proprietors of "designs or models."

THE ARCHITECTURAL ASSOCIATION SKETCH BOOK.

THE twelfth volume of the third series of the A.A. Sketch Book worthily maintains the reputation and high standard of former volumes, whether one regards it as an exhibition of the draughtsmanship of present-day architectural students or as a museum of valuable records of excellent architecture of the past. The catholicity of our modern study and appreciation of all that is good in old work is reflected in the range of subjects illustrated, extending as it does in date from Greco-Roman work to Le Petit Trianon, in locality from Shropshire to Constantinople. The care and discrimination of the editors, Messrs. W.G. B. LEWIS and THEODORE FYFE, are shown by the fact that there is not a single one of the seventy-two plates that any reasonably minded critic would wish omitted, or would consider unworthy of a place in a representative collection of old work.

Partly, perhaps, by reason of our present-time sympathies, but chiefly, we think, from the character of the past achievements of the A.A. Sketch Book in the thirty-five volumes that have preceded the one now before us, Renaissance work predominates over Mediæval, but even so we have such interesting buildings in our own country measured and drawn as the late Norman Keep of Castle Hedingham; the Priory Church of the Holy Trinity, Twynham, better known as Christ Church, Hants; the choir and lantern tower of the Abbey Church of the Holy Cross, Pershore; whilst the measured drawing of two bays of the cloisters of Norwich Cathedral is both a valuable record and an admirable example of careful study. An interesting specimen of our latest English mediæval work is the rood-screen from Charlton-on-Otmoor, which a young student might easily mistake for earlier work but for the elaborately enriched shafts and the green paint in the colouring. Green, if original, is always a mark of late date in fifteenth-century decoration, the earliest examples of which in screen work are restricted to white, red, and gold; then later we have black and blue, and last of all green. The picturesque in English mediæval work is represented by sketches of half-timber work at Ludford and Ludlow by Mr. A. N. PRENTICE, and at Shrewsbury by Mr. EDWIN FORBES.

Greenwich Hospital and Hampton Court Palace are the principal subjects illustrating English Renaissance work. Of the former we have a general plan marking the various parts erected from the designs of the several architects employed, which should be useful to students for reference. We wish to protest against the mis-spelling of HAWKESMOOR'S name that is now the fashion and is followed in the plan. He himself spelt it with an "e." We have measured drawings and details of the principal fronts of King CHARLES'S block and King WILLIAM'S block as well as the dome of Queen MARY'S block, all very useful and interesting. We are particularly struck with the refined character of the mouldings by JOHN WEBB in the river front of King CHARLES'S block, which, though Renaissance in form, are quite Greek in delicacy, yet at the same time not deficient in vigour. We take it for granted that though the reproductions are reduced to about one-quarter full size the originals accurately represent the actual contours. From Hampton Court we have sections through the Fountain Court and Chapel, with details more particularly of the Chapel.

The chief Renaissance examples from abroad are the Palazzo Pietro Massimi alle Colonne at Rome and the Porta del Palio (Porta Stuppa) at Verona. The former was the work of BALDASSARE PERUZZI and one of his best. The parts of the palace here illustrated by measured drawings are the cortile and the entrance loggia, with the columns, from which is derived the popular name by which this palace is distinguished from the adjoining one of the owner's brother, ANGELO MASSIMI, although, as Mr. ANDERSON says, the columns were themselves perhaps introduced in punning allusion to or symbolism of the full name of the ancient MASSIMI family. The details given well illustrate the Greek feeling of PERUZZI'S design for the Massimi palace, and it is quite pleasant to be able to compare this work of the Italian master of the sixteenth century with that of our own JOHN WEBB, on which we have already remarked, and to speculate as to whether WEBB was influenced by this work of PERUZZI'S or whether he was led to a similar result by a cognate line of thought and taste. The excellence of the work produced by both is at least for us a lesson of the value of the departure each alike pursued.

The Porta del Palio, Verona, is a characteristic work of the great engineer-architect, MICHELE SAN MICHELI, and as a study of expression in architecture is worthy of record by the perspective drawing and detailed elevations contributed by Mr. MAURICE LYON, travelling scholar of the Liverpool University School of Architecture.

A measured drawing of the cornicione of the famous Strozzi Palace is a desirable inclusion, though its value would have been considerably increased if the delineator had investigated and shown how the 7 feet 4 inches projection is constructed and supported. In the days of the Gothic revival in the last century architectural students were always admonished to measure every stone and to ferret out the construction of everything they drew; nowadays it is too much the habit in studying Renaissance work to regard architecture as entirely a matter of surface and profile. In the present instance not a single masonry joint is shown, and the cornice might be in plaster or reinforced concrete for all the indication of construction that is given. In all good architecture design is regulated by construction, and to attempt to study design without construction is to grasp the shadow without the substance, the effect without the cause.

The plan and elevation of the façade of Le Petit Trianon, Versailles, the latter tinted in the French manner, is an admirable example of effective rendering of geometrical drawing, and well conveys the charm of this little gem of the later French Renaissance, the design of JACQUES ANGE GABRIEL, dated A.D. 1766.

The Flamboyant work of the church of Notre-Dame, at Caudebec-en-Caux, the little old-world town on the lower Seine, is well illustrated by wash perspectives of the west-end and tower by Mr. C. WONTNER SMITH, and excellent measured drawings and perspective sketches in pencil by Mr. A. E. MARTIN, who gives a plan of the whole church, an internal elevation and section of one bay, and details of parts. The spirit of Flamboyant work has seldom been better expressed than in the sympathetic sketches by Mr. MARTIN of two of the smaller internal doorways of the church.

Curious are the panels from Dordrecht and Malines sketched by Mr. A. E. MARTIN, particularly the wall panel from a now demolished house in Dordrecht, representing Old London Bridge, as is shown by its inscription, "inde Londen Bruick," and dated 1617. Not only curious but informing are the examples of metal work in bronze and wrought-iron from Siena and Venice, excellently drawn by Mr. C. WONTNER SMITH, albeit the flagstaff-holder from the Palazzo del Magnifico is a well-known example.

A valuable set of drawings comprises plan, sections, and elevations of the highly interesting Romanesque church of S. Maria Maggiore at Toscanella, with its round-arched Italian Gothic west front, the date of which with the two western bays is given as A.D. 1206, that of the eastern portion being A.D. 1050.

From Constantinople we have an expressive drawing, though somewhat depreciated in reproduction, of the interior of Santa Sophia by Mr. ARTHUR E. HENDERSON; a measured drawing of the elevation of the Palace of the Porphyro-genitus or Palace of Belisarius, by Mr. JAMES B. FULTON; Byzantine work between the dates A.D. 912 and 958, and perspectives of the exterior and interior of the Moslem mosque of Sultan SULEIMAN, date A.D. 1550-6, by Mr. HENDERSON. Moslem work is further illustrated by Mr. A. N. PRENTICE'S measured plan and section of the Torre de la Cautiva at the Alhambra.

Greco-Roman is represented by a drawing of a pilaster capital, probably from Athens, and now in the British

Museum, the interest of which lies mainly in its kinship to a favourite type in use amongst Renaissance designers, particularly in Italy and France, and emphasising the truth that there is scarcely a form of decorative feature employed by the men of the Italian Renaissance that has not its prototype in the classic work of Greece and Rome, if we only knew where to look for the originals.

Drawings of coloured decoration necessarily largely suffer by reduction of scale and monochromatic rendering in reproduction, but it was worth while to include the examples from the Baptistery at Ravenna, RAPHAEL'S work at the Vatican, and the Palazzo Publico at Siena.

The frontispiece of the volume is adorned with a pencil sketch by Mr. REGINALD BLOMFIELD of a cartouche in stucco by IL ROSSO in the gallery of FRANÇOIS I. at Fontainebleau, so wonderfully reproduced that one gets even the sheen of the lead.

ARCHITECTURE: ITS TRUE PRINCIPLES.—V.

By R. OWEN ALLSOP.

ARCHITECTURAL EFFECT.

THE true value of public criticism is scarcely appreciated. It prevents a prostitution of end to effect. Thus the opinion was once expressed to us by an architect, that all window cills should internally be seven feet from the floor line. The assigned reason was the fine space for a showy dado round the room. Common sense and the public rightly say that this is ridiculous; the one pointing out that nothing is so depressing as high lighting, and the other naturally enough that they want a window to look out of. So in music, the composer tends towards that which shows technical difficulties overcome —the public say they want a tune. The artist will admire a work greatly because of the skill shown in technical management—the buying public ask for an intelligible picture. The worship of technique leads the professional man—he that lives by practice of the art—to extremes, generally losing sight of the main end and aim; for no better chief principle can be laid down but that art should be as practical as nature—that is, serve some practical end. Of this exaggerated technique we get societies established for finding out what a poet really meant—if indeed he meant anything at all. The useful "man in the street" who keeps things generally within reasonable bounds, would say that he prefers intelligible poems.

It is especially a failing of the architectural critic to run down popular criticism, whereas this same criticism it is that keeps a house a house, a church a church, and neither of them a mausoleum. The plain man asks for an ornamental building and naturally feels hurt with a barn. It is one of the affectations, writes RUSKIN, that ornament may be overcharged. The sentence and its context is too widely known to need repetition. It is a fact worth much that the populace can always appreciate a really fine work of architecture. They may not necessarily be able to differentiate between that which is excellent and that which is bad, but the natural untrained eye quite fully appreciates that which is superlatively excellent. This is an important point in any consideration of the nature of architectural effect. It is always necessary to distinguish between want of education and genuine bad, warped taste. If the fact—of which we need not doubt—that the public will admire a design if elaborate and ornamental, were founded on bad taste, there would be no power of appreciating that which is excellent. Bad taste is positive; lack of knowledge or deficient education negative.

It is not supposed that every one appreciates the rationale of the *entasis*. Yet all with a natural eye should be able to appreciate its effect. The true entasis we know, merely a correction, be it noted, of a If "natural" then the natural eye must ciate, no especial education would be a fine dome, it is an object of the artist it is no more—to The principle whereby the effect of magnificence was produced is another matter. It does not concern the beholder. Principles being means to an end, it is not requisite that all should have a knowledge of such. It is the business of the creator of his object to attend to this matter.

Does not the public appreciate fine architecture? If we say no, then vain is the work of the architect. All our efforts are for ourselves, the microscopically small minority. The truth is that the "whole" effect of a building is plainly perceived by all, probably more heartily at times by the natural eye than by that satiated with much consideration of architectural forms. Where, then,

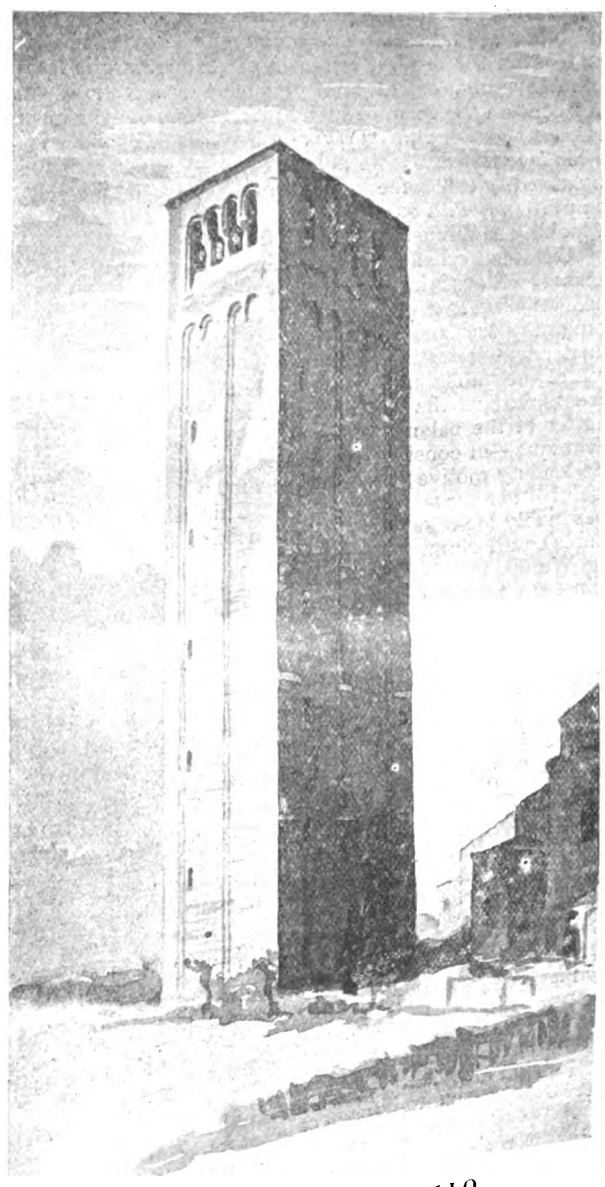

FIG. 14.—CAMPANILE, TORCELLO.

the sense of this abuse of the public? There is far too much thrusting of peculiar views down the layman's throat.

The finest part of architectural effect, the harmonious grouping and large broad effects of composition, does verily appeal to the public eye, and he that under an impression of lowering himself to suit a lower taste produces the "ornamental" as distinct from the "architectural," does truly lower himself to a very low and contemptible plane indeed.

It is frequently urged that public taste, or what is, inconsiderately, called want of taste, influences modern architecture. The only way in which such an effect can

Digitized by Google

arise is an indirect one: that, inasmuch as the architect comes out of the body public, then if the taste of the community is corrupt, the individual cannot free himself from the original sin. Where is the architect of long-standing practice who will solemnly aver that his clients have swayed him in his design? If there be any such instances, they must either result from wilful pandering or a despicable weakness of character. Whatever modern architecture may be, it is the creation of modern architects. To endeavour to lay the blame on the public is a miserable subterfuge. Quite recently Professor HERKOMER has dilated on the *benefits* (to art) of the existence of the Philistine. In architecture, as we have suggested, such a one prevents the making of seven-foot window cill lines, and other absurdities. The architect who does not give ear to even the crudest criticism of architecture is losing valuable hints, or, at least, ignoring observations that may contain the germ of such hints. None but the inconsiderate boor, or the very young in years, will tell a man to his face that his taste is bad. If one cannot rather, as suggested, glean some golden grains of truth, the call is to uplift and, with considerateness, suggest a different way of looking at things.

Architectural effect in the main concerns great building masses, relieved in sunlight, shadow, and shade. Immediately we lose sight of the fact that it is only a small something over and above the great art of well building we must needs go astray in the fields of dilettantism. The pull of the public and the pull of the architectural profession maintains the art *in equilibrio*; for equilibrium is a matter of the balance of forces. The one force tends to technique—in constructive matters to a *tour de force*—as the leading motive; the other to that which is practically useful either *per se* or in its effect. This being so, we might reasonably look for many true principles at the position of stable equilibrium.

We are most of us pleased with the interior of Westminster Cathedral, mainly, doubtless, from great weariness of expressionless and hackneyed ornament; but Philistinism will hint at barns and railway arches, and we are perforce brought to remember that buildings may be both bold and expressive in mass, and rich and refined in subordinate parts. The Campanile on the Isle of Torcello, at Venice, will always interest the architect, from its mere proportioning—contrasted dimensions—and its effective concentration; but the plain man will ask what it is, and himself adjudge that it is an ordinary kind of water tower, neither more nor less. While we are all so ready to talk of simplicity and plainness as chief merits, we have a sense of misgiving that, after all, magnificent architecture may—and often must—have abundant richness, unless that which is purely dignified, forbidding or awe-inspiring, is the designed end and aim. And we must all often feel that one great problem in architectural design is how to gain richness without sacrifice of breadth—an impossible problem possibly to solve in terms, any more than we could discover some secret as to how others could produce a TURNER masterpiece in rainbow hue. We may perhaps see that a rich effect in true architecture has something to do with geometrical simplicity of great parts and the constant appearance in subordinate parts of what—taken by themselves—might be considered harsh and uncompromising geometrical lines. Such can be plainly seen in works of the greatest richness, such, for example, as the western façades of Amiens or Rheims. The principle involved would seem to be to contrast the rigour of that which is mathematical with the free abandon of forms that give a wealth of broken light and shade; with, as resultant, that mutual enhancement which seems observable when, for example, a fanciful silver vase is placed upon a plain velvet-covered cube as base.

There is architectural form, and also architectural effect from such form, from a multitude and from a galaxy of forms, harmoniously composed. The porch of St. Mary-le-Strand has elegant columns and entablature; but the main effect is in the disposition of parts; and, added to this, after midday the sun's rays aggrandise the effect of the architectural form, and the whole is relieved by a magnificent asymmetrical shadow. It would seem as though, to many, elegant columns and entablature constitute a whole effect, whatever the disposition of parts—the composition. This, which might be suggested as the characteristic of the half-education architectural, does not pertain where the wholly unsophisticated eye is concerned, which naturally sees whole effects and is not greatly concerned as to whether the section of a moulding is cylindrical or parabolic. In the result it seems suggested that a main principle of architectural design should lay down that refinement in mass—for that is what it comes to—must precede refinement in detail, otherwise a possible grand conception will be lost in petty littleness. True architectural effect concerns main masses of building—solids and voids, arches, lintels, piers, columns, and the like. These are the pot-hooks and hangers of the art, and style details the flourish and the curl, and of about the same significance and value when compared with the power of conveying thought by definitely formed characters.

(To be continued.)

TUDOR ARCHITECTURE.*

WHEN the first part of this book appeared last year it received enthusiastic praise on every hand for both its matter and the manner of its production. Part II., which has now been issued, attains the same high level, and we have no doubt that the remaining part when it appears in the course of the next few months will give equal pleasure to subscribers—the set of three volumes forming (to employ a much-abused phrase) a valuable and almost indispensable addition to every art-lover's library. It might be well to again mention that the compilation of the work was first entrusted to Mr. THOMAS GARNER by Mr. BATSFORD, who was anxious that his series of monumental publications on old Domestic architecture in England should be completed by the inclusion of one dealing with the eventful Tudor period. When Mr. GARNER died the materials were put into the hands of Mr. ARTHUR STRATTON, who, like Mr. GARNER, had shown himself especially attracted by this phase of architectural evolution. The completed work is to consist of 180 folio plates, of which 120 will be collotype photographs, the remainder being sheets of measured drawings and sketches of details by E. GARRATT, W. H. GODFREY, A. STRATTON, W. TWOPENY, H. TANNER, junr., and others. An important feature of Part I. was an illustrated introduction treating of the Tudor period. The descriptive text in the second part is confined to particular buildings in their historical and architectural aspect.

The first house dealt with is Compton Wynyates Manor House, Warwickshire. There are four plates of it in this part, two of which are beautifully-produced photographic views; the third is made up of details of the entrance porch, and the fourth of details of the large bay window at the daïs end of the hall. The house may be regarded as typical of the large number erected about this time, when the owners were divided between the military tradition of previous generations and the necessity for obeying the peace-compelling laws of HENRY VII. The letterpress says:—"A moat, which was filled up in CROMWELL'S day, originally surrounded the house, and to the west, facing the principal entrance, was a second piece of water: defence by water and the situation of the house being the only essentially protective measures discernible. Indeed, this is one of the earliest examples of a manor house that is not only non-castellated but makes no pretence of being so." The present south-west front has, however, something of a martial air through the additions carried out in the reign of HENRY VIII.; but they are only sufficient to increase the picturesqueness and could never have been seriously intended for defensive purposes.

* *The Domestic Architecture of England during the Tudor Period.* Part II. Illustrated in a series of photographs and measured drawings, accompanied by an historical and descriptive text, including a large number of plates and details, by Mr. Thomas Garner and Mr. Arthur Stratton. (London: B. T. Batsford.)

Digitized by Google

However, like many other houses of the period, the principal hall is at the back and accessible only through a gatehouse and across a courtyard. Compton Wynyates has a strong claim to be accepted as in the true vernacular style. Sir WILLIAM COMPTON, to whom the building mainly owes its present appearance, was a much-travelled courtier, but, fortunately, he was not inspired to make any ostentatious show of being fashionable in the sense of being convinced that things are better done abroad. The English craftsman was, he considered, good enough to erect and adorn his country seat, and in consequence there is no trace of foreign influence even in the ornament which is lavished upon the interior.

Layer Marney Hall, Essex, is another instance of a building whose owner, though inspired by no warlike ambition, was unable to entirely cast aside the traditional instinct for securing self-protection. The entrance gateway is in a tower eight storeys, or 70 feet, high; as a contrast to this military feature the windows are remarkable for their number and size. The customary battlement on top is replaced by a parapet, which, like much else of the ornament, has a strong Renaissance feeling. In the letterpress it is remarked that its pretentiousness suggests that the owner who erected the entrance gateway was thinking of a personal monument after the manner of the *nouveau riche*. It would almost appear as if a large proportion of the most prominent men of the reigns of HENRY VII. and HENRY VIII. were self-made men who, when their days of prosperity came, were able to found their house wherever their fancy prompted, instead of being bound down by any family tradition to some particular site.

An exception was Cowdray, near Midhurst, which belonged to successive generations of DE BOHUNS until the male line became extinct in 1499. It was sold by a son-in-law to the Earl of SOUTHAMPTON, who obtained a Royal patent to add to his park at Cowdray and to build there an embattled castle of stone. From him it passed to Sir ANTHONY BROWNE, his half-brother, and then to the latter's son, who became Viscount MONTAGUE. We are told that Cowdray must at this time have been as beautiful and complete a Tudor house as any in England. Unfortunately the north and south wings were destroyed by fire in 1793. According to the book under review the story of the fire is one of extraordinary carelessness:—

> The family were not living in the house at the time, as it was undergoing repairs. The fact that the fire arose from the workmen burning charcoal in the room used for their carpenter's shop at the top of one of the towers shows that no very careful supervision was exercised: it is also said that the fire hose and buckets were locked up in the small hexagonal stone building a short distance away to the north, the key of which was mislaid. The north gallery, where nearly all the pictures and valuables and much of the furniture had been put temporarily, was immediately below the room where the fire broke out. The destruction could hardly have been more complete.

A quite different type of building is shown in the Guildhall, Lavenham, a timber-framed structure dating from the early sixteenth century. The growing power of the merchants is here indicated in the possession of so important a meeting-place. On the suppression of the Guild of Corpus Christi it was utilised as a town hall, then as a prison, a workhouse, a set of cottages, a granary, and a wool store.

Grey Friars or Ford's Hospital, in Coventry, is another "plebeian" building included in Part II., which was erected with as much or more attention to ornate detail as any residence for the nobility or gentry. It was endowed and built by WILLIAM FORD in 1529 for the accommodation and maintenance of five poor men and one woman. The west front, we are told, presents some of the most beautiful sixteenth-century half-timber work to be found in the country. Mr. E. GARRATT has produced a noteworthy page of details, which acts as a worthy supplement to the striking photograph showing the interior of the narrow courtyard, on each side of which the dwellings are arranged. The barge-boards are covered with pattern, and the design of the window tracery shows the greatest variety. A third building serving a humble purpose, but with strong claims to attention, is the "Marquis of Granby Inn," Colchester, which contains a wonderfully fine ceiling with moulded and carved beams of excellent design and workmanship. It is sometimes held that this inn was originally an important mansion. Possibly these decorative features may have been taken from some residence in the neighbourhood—a method which then, as now, found considerable favour among those who were enriched by the transaction.

The Domestic architecture of the Tudor period is full of suggestion to architects of the present day. It marks the highest attainment of native mediæval talent and was the outcome of many social changes which brought the sixteenth century at a bound considerably nearer the ideas of the present day. The plates, general and detail, in this second instalment of the interesting portfolio on the subject are heartily to be commended as revealing the beauty of England's possessions in houses throughout the length and breadth of the land at that period.

THE BUDDHIST AND HINDU ARCHITECTURE OF INDIA.*

THE literary records of India, beginning with the Rigveda, go back to about 1500 B.C., an earlier date than those of any other Indo-European people; but they supply hardly any information about chronology. We are accordingly very largely dependent on archæology in its various branches for the reconstruction of the external history of the religious and social institutions as well as of the political events of early times. The study of archæology is, therefore, relatively more important in India than in perhaps any other country of the present day. But the ancient monuments in which so much information lies buried have been disappearing from the face of the land. Thousands have been lost for ever. Vast numbers were destroyed or mutilated by the Mohammedan invaders in bygone centuries. Many others have from time immemorial been used as quarries by neighbouring villagers. Others have fallen into irretrievable ruin simply through the ravages of time. Some antiquities of priceless value are known to have been destroyed within the last century. Thus the great Stupa of Amaravati in Southern India was standing less than 100 years ago, but now there is hardly a trace of it left, though several of its sculptures have been rescued for museums. It is recorded that about sixty cartloads of ancient Buddhist sculptures were removed from Saranth, near Benares, and thrown into the neighbouring river to form the foundations of a new bridge about a century ago. Much damage has thus been done in the process of making roads, railways, and bridges. Great harm is also done, in Southern India especially, by the practice of pulling down old shrines and using the materials for building new ones. Buried sites have further been often greatly injured by the operations of untrained and irresponsible excavators, and innumerable sculptures of great archæological value have been thus dispersed and lost. This disastrous state of things at once attracted the attention of Lord Curzon on his arrival in India as Viceroy. Without delay he proceeded to reorganise the Archæological Department on a permanent and systematic footing. He then, in the year 1904, passed the Ancient Monuments Preservation Act, by which he has conferred a benefit of the very greatest importance on India. The ancient monuments of the country are now under the direct charge of the Archæological Department. All that survive will henceforth be carefully preserved and kept in repair. Archæological finds will be placed in Government museums and all traffic in them put a stop to.

In the pre-Buddhistic phase of Indian religion from which Hinduism is directly descended, carved images of the gods and temples for worship were equally unknown. And in the absence of images, structural places of worship would not be wanted. The fire and Soma ritual of this early age was conducted in an open air enclosure, or in connection with the domestic hearth. None of the architectural or sculptural antiquities which survive in India can, with one exception, be dated earlier than 260 B.C. These earliest remains are all connected with Buddhism. The one excep-

* Abstract of a paper read before the Society of Arts by Professor A. Anthony Macdonell, M.A., Ph.D., F.B.A.

tion is a brick Stupa or relic mound at Piprahwa, on the Nepal frontier, which was explored ten years ago, and has, with probability, been assigned to 450 B.C.

It is with the reign of Asoka (264-27 B.C.), whose rule extended practically over the whole peninsula, that the history of Indian art can really be said to begin. Originally an adherent of the Brahman religion, he became a convert to the doctrine of Buddha and devoted himself to promoting its interests during the remainder of his life.

The history of Buddhist architecture in India extends over about nine centuries, and may be divided into three roughly equal periods. The earliest period reaches from 250 B.C. to 50 A.D. The monuments which survive from this period are almost exclusively the work of Buddhists. It was the Buddhists who introduced the use of stone in architecture at the commencement of this period. For some centuries before, the architectural use of brick had been known, as is proved by the Stupa of Piprahwa, which probably dates from 450 B.C. But the ornamental buildings of the pre-Asokan age must have been built of wood, like the modern palaces of Burma, only the substructures being made of brick. The whole history of Indian architecture points to previous construction in wood, the stone monuments being, to a large extent, imitations of wooden models. The second, and as far as Buddhist sculpture is concerned, best period, extends roughly from 50 A.D. to 350 A.D., the third period from 350 to 650 A.D.

The remains of Buddhist art in India are almost entirely architectural and sculptural; sculpture practically always appears in connection with the architecture, and invariably in the service of religion. Early Buddhist architecture may be divided into three main groups;—(1) "Stupas," or relic mounds; (2) "Chaityas," or places of worship, corresponding to our churches; and (3) "Viharas," or dwellings for the monks.

The "Stupa" is a dome-shaped structure which was a development of the low sepulchral tumulus or mound of earth, in which baked bricks were substituted for earth with a view to durability. Their purpose was to serve as monuments enclosing relics of Buddha or of Buddhist saints, which were placed in a stone coffer. Some, however, contained no relics, but were only commemorative of important events or miracles connected with the history of Buddha.

As representative of this form of structure we may take the large Stupa at Sanchi in Central India, dating in all probability from the third century B.C. Upon a low circular drum a hemispherical dome was erected. This dome was surrounded by a procession path forming the upper rim of the drum. On the top of the dome was a boxlike structure surmounted by an umbrella (the Indian emblem of sovereignty), and surrounded by a stone railing. This structure is usually called a tee (a Burmese word). The tee has disappeared from all the Indian Stupas, but its form can be seen from the Stupas surviving in Ceylon, as well as from stone models and sculptural representations preserved in great numbers in India. The Stupa itself was surrounded by a massive stone railing, with gates on four sides, enclosing a procession path and a sacred precinct. Both the rails and the gates were unmistakable imitations of wooden models.

The earliest Stupas were very low in proportion to their diameter. The oldest known example stands only about 22 feet high, with a diameter at the base of 116 feet. As time went on the relative height increased. Thus the great Stupa at Sanchi, erected some 200 years later, is 54 feet high, while the basal diameter of the dome is 106 feet. The Stupa of Sarnath, near Benares, was erected several centuries later. Here the height is 110 feet above the surrounding ruins and 128 feet above the plain, with a diameter of 93 feet. In other words, the Stupa shows a tendency to assume the shape of a tower.

Concurrently with the elongation of the Stupa we can see an elongation taking place in the tee also. The next step is a further elongation of the tee with a corresponding diminution and flattening of the main body. In an example in Nepal the umbrellas have disappeared and assumed the shape of thirteen roofs. In the Indian rock-cut specimens there are never more than three umbrellas, but in many of the model stone Stupas in Behar there are nine. Proceeding to Burma, we find the process going still further. Finally, we come to the last development in China, where the tee is practically all that is left.

I do not think it would be easy to find a more remarkable example of evolution in art. The process of development, when pictorially represented in its successive stages, almost resembles that of growth in the vegetable world. Here you have an Indian architectural ornament, consisting of a few superimposed umbrellas only a few feet high, finally transformed into a nine-roofed Chinese pagoda reaching the height of 200 feet. Fergusson, in his "History of Eastern Architecture," suggests that the Chinese pagoda is derived from the Stupa, but he nowhere tries to prove the connection, though some of the illustrations in his own work supply part of the evidence.

The second class of Buddhist religious buildings, the so-called Chaityas, are the exact counterpart of Christian churches, not only in form, but in use. Till recently only rock-cut examples, to the number of about thirty, were known in India. The existence of these is a great advantage for the history of architecture in India, because they are still the same as when they were originally designed, some of them well over 2,000 years ago.

The typical Chaitya consists of a nave and side aisles, terminating in an apse or semi-dome. The pillars separating the nave from the aisles are continued round the apse. Under the apse and in front of its pillars is the rock-cut Stupa, nearly in the same position as that occupied by the altar in a Christian church. The tee was doubtless usually surmounted by a wooden umbrella, but this has everywhere disappeared except at Karli, the finest Chaitya cave in India. The roof of the Chaitya is semi-circular. The door is opposite the Stupa. Over the doorway is a gallery. Above this is a large window shaped like a horse-shoe. This window is constantly repeated on the façade as an ornament. The outward appearance of the structural Chaitya was for a long time somewhat conjectural, but some recent discoveries of ancient structural Chaityas in the Bombay and Madras Presidencies have confirmed these conjectures, especially as regards their wooden origin.

The excavation of these Chaityas extended from 260 B.C. to about 600 A.D., and the development of their style can be followed step by step throughout these nine centuries. The most important of them is called the Lomas Rishi Cave (the Cave of the Hairy Sage). The front is carved so as to represent in rock the form of the structural Chaityas of the age. The posts, the five rafters, and the blocks at the sides are all imitations of wood. The door has also the primitive feature of jambs sloping inwards, in imitation of wooden buildings. The hall inside has a semi-circular roof. It is adorned with no kind of ornament, but the granite surface of the rock is highly polished throughout. Beyond the hall there is an almost circular apartment. This is a remarkable feature, because it represents an experimental stage in rock-excavation. It is evidently an attempt to represent the shape of a Stupa in the form of a hollow chamber, instead of, as in later excavations, leaving a mass of rock at the end of the nave to be carved into a solid Stupa. All the most important examples of Chaityas occur at six places in Western India. As we pass from the earliest to the latest specimens, we can clearly trace progress towards stone construction on the one hand, and degeneracy of cult on the other. In the oldest the pillars of the nave slope inwards, as in wooden structures, to resist the thrust of a circular roof. The rafters as well as the screen were made of wood, but these have long since disappeared. In later specimens, the pillars of the nave and the jambs of the door become straight, and the screen consists of rock.

At Ajanta there are four Chaityas. The second oldest of these shows a very interesting transition from wood to stone. For while the ribs of the vaulted roof of the nave were of wood, the ribs in the aisle are of stone, copied from wooden forms. The third Chaitya at Ajanta is at least four centuries later, dating probably from the fifth century A.D. Here all trace of woodwork has disappeared, earlier wooden forms being everywhere reproduced in stone. The rail ornament so common in the earlier caves has vanished, while the horse-shoe window-heads employed as a decoration on the façade are dwarfed. A striking change is the fact that figure sculpture has superseded the plainer architectural forms of the earlier caves. The greatest change, however, is this. Buddha has now been introduced in all his attitudes. Only ordinary mortals are sculptured in the earlier caves, while Buddha never appears. Now he is even the object of worship, his image being placed in front of the Stupa itself, which alone was adorned in the older Chaityas. In place of the atheism of the Buddhism of an earlier age, we find ourselves here confronted with an overwhelming idolatry. In the last of the Ajanta Chaityas, which dates from about 600 A.D., the sculptures are more mythological than in the previous cave, evidently approximating to the iconography of Brahmanism.

Finally, we have at Kholvi what is probably the latest Buddhist Chaitya cave in India. The Stupa which it con-

Digitized by Google

tains is no longer solid, but is hollowed out into a cell in which an image of Buddha is placed. This marks the last step in the development of the Buddhist temple. A link connecting this formal stage with the later Jain and Hindu temples is to be found in an old structural Vishnu temple dating from about 700 A.D. Here the Stupa is superseded by a cell for the image, but this cell still has a semi-circular back and is separated from the outer wall by a passage for circumambulation, which is a continuation of the aisles as in the Buddhist Chaitya. The transition is completed by the next step when the cell is made square.

Thus Buddhism, which had originally emerged from the older Brahmanism, again relapsed in India, after more than 1,000 years, into a later form of the same religion.

Besides the structural Stupas or the rock-cut temples, there arose Viharas or monasteries, as residences for Buddhist monks. Our knowledge of these is still more dependent than in the case of Chaityas on the rock-cut examples. There are about 900 Buddhist caves of this class in India, besides about 100 belonging to the Jain and Brahman religions. According to the rock-cut specimens, the Viharas consisted of a hall (sala), generally square, but sometimes oblong, surrounded by a number of cells or sleeping cubicles, and shaded by a verandah in front. The cubicles in the oldest caves usually contain a stone bed. There is generally only a single floor, but examples of two-storeyed Viharas are not wanting. The only examples of Viharas in Eastern India are found at Udayagiri, in Orissa.

All the rest are found in Western India. Probably about forty of these were excavated before the Christian era. The four most important of these occur, one each at Bhaja and Bedsa, and two at Ajanta. That at Bedsa is specially interesting because the Vihara here has an apse. The second of the early Ajanta Viharas, dating from about the end of the first century B.C., is a transitional example. For here we first meet with a Vihara ceiling supported by pillars in the centre, four in number. In all these early Western Viharas there is no figure sculpture, no reliefs, no carved emblems even. The only ornament consists of horse-shoe arches and the Buddhist rail as a string course, with an occasional pilaster.

Ajanta has more Buddhist Viharas than any other place, the number being twenty-two. These are specially important as supplying a complete series of examples of Buddhist art, without any admixture from Hinduism or any other religion, extending from 200 B.C. to 600 A.D. As they contain many inscriptions the dates of the caves are fairly well known, and thus help to fix the chronology of other groups. The caves of Ellora are, however, the historically most interesting with reference to the inter-relation of the three Indian religions, Buddhism, Brahmanism, and Jainism. For here we have side by side three groups of caves (altogether thirty-three), distinctly representing those religions, while the transitions from one to the other can be clearly traced. Of the Buddhist group of twelve, eleven are Viharas. The sanctuaries of most of these contain figures of Buddha seated, but with the feet down and not folded under them. Thus, the Buddhist monastery is becoming a place of worship in which figures of Buddha are ousting the monks from their cells. These Viharas come down to about 700 A.D., at which point the earliest Brahman examples begin. There are here three two-storeyed caves which illustrate clearly the transition from Buddhism to Brahmanism. The first is entirely and unmistakably Buddhist. The second is similar in plan, and the sculptures are still all Buddhist, but these deviate sufficiently from the usual simplicity to have justified the Brahmans in appropriating this cave as belonging to their religion. The third is very similar in plan to the preceding one, but the sculptures are all unmistakably Brahman. It is evidently the earliest Brahman cave, being a close copy of the preceding Buddhist example.

We have thus arrived at the beginning of the Hindu period of Indian architecture. We have seen that the Buddhists were the first builders and carvers in stone in India, beginning in the third century B.C. It is only on Buddhist monuments that we find the earliest representations of Hindu deities. But the oldest remains of independent Hindu art, either sculptural or architectural, only date from several centuries after the beginning of our era. These considerations in themselves justify the presumption that Hindu architecture is derived from the older art of the Buddhists. This presumption is borne out by the fact that the earliest extant Hindu samples are practically identical in form with the latest Buddhist specimens, differing from these latter only in having the image of a Hindu deity, instead of one of Buddha, placed in the shrine. Again, at Ellora, some of the sculptures in the earliest Hindu cave temples are hardly distinguishable from those of the latest Buddhist caves at that place.

(To be continued.)

GLASGOW INSTITUTE OF ARCHITECTS.

THE annual general meeting of the Glasgow Institute of Architects was held last week in the rooms, 187 Pitt Street, Mr. George Bell, F.R.I.B.A., president, in the chair. The Secretary submitted the forty-first annual report, which stated that the membership now stood as follows:—Eighty-six fellows, eighty-one associates, forty lay members and twenty-two student members, giving a total of 229. Several architects practising in Bournemouth approached the Council regarding the question of municipal officials and architectural work, and a reply was made expressing the willingness of the Institute to co-operate in any practicable scheme of reform. The attention of the Council was called to the condition of the local wood carvers in consequence of unemployment. Sympathy with these craftsmen was expressed, and the members agreed to do what they could in the direction of giving a preference to local labour where possible and in the best interests of the works under their charge. From the report it appeared that the provisions of the Town-Planning Bill, as introduced by the Government last session, were the subject of consideration by the Council in view of the far-reaching effects of such a measure in matters of the utmost importance to architecture. While the principles of the Bill were generally approved of, the Council was of opinion that the benefits which it is likely to confer would be increased and the danger of maladministration lessened by the inclusion of clauses providing for (1) the statutory creation of locally appointed committees of experts to whom town-planning schemes should be referred and whose suggestions should be submitted to the Local Government Board; (2) specific permission for the R.I.B.A. and its allied societies to appear before and make representations as "persons affected" at inquiries held by the Local Government Board before the approval of town-planning schemes. The Scottish members of Parliament on the House of Commons committee were written to, asking them to support the foregoing recommendations. A new clause embodying them in part was ultimately accepted by the committee and will be incorporated in the Bill on its reintroduction this session. On the suggestion of the R.I.B.A. the Council has appointed a town-planning committee for this district, which will give special consideration to the subject and will be prepared, on the Bill being passed, to advise and assist such local authorities within the Institute's province who contemplate taking action under its provisions. The report further states that the acquisition of more suitable premises for the Institute has from time to time been the subject of serious consideration by the Council. With the assistance of the house committee, negotiations have latterly been entered into with the Institution of Engineers and Shipbuilders in Scotland for a share of their handsome new premises at 35 Elmbank Crescent. These have now resulted in an agreement, under which the Institute will obtain occupation at Whitsunday. The threatened demolition of Newark Castle was brought before the Council. After full consideration a letter was forwarded to the owner, Sir Hugh Shaw-Stewart, Bart., pointing out the irreparable loss to art and history if this beautiful and characteristic example of early Scottish architecture were demolished, and expressing the hope that its removal would be averted, unless imperative considerations necessitated it. The Council were glad to note that on the representation of the Institute and others, Sir Hugh had now decided to allow the castle to remain. The report was adopted, and the Council for the ensuing year was elected as follows:—Messrs. James M. Monro, Alexander M'Gibbon, Andrew Balfour, Thomas Baird, jun., George Bell, Alexander Skirving, Robert Miller, John B. Wilson, John A. Campbell, John James Burnet, James A. Morris, Henry Mitchell, John Watson, R. D. Sandilands, Neil C. Duff, J. K. Hunter, James Lochhead, Alexander Wingate and W. J. Blain. The treasurer's accounts, which were submitted and approved of, showed that the funds were in a satisfactory position. A meeting of the newly elected Council followed, at which office-bearers for the year were appointed, viz.:—President, Mr. George Bell, F.R.I.B.A.; vice-presidents, Messrs. John B. Wilson, A.R.I.B.A., and Alexander Skirving, F.R.I.B.A.; auditor, Mr. James M. Monro, F.R.I.B.A.; secretary and treasurer, Mr. C. J. MacLean, writer, 115 St. Vincent Street. The various committees for the year were also appointed.

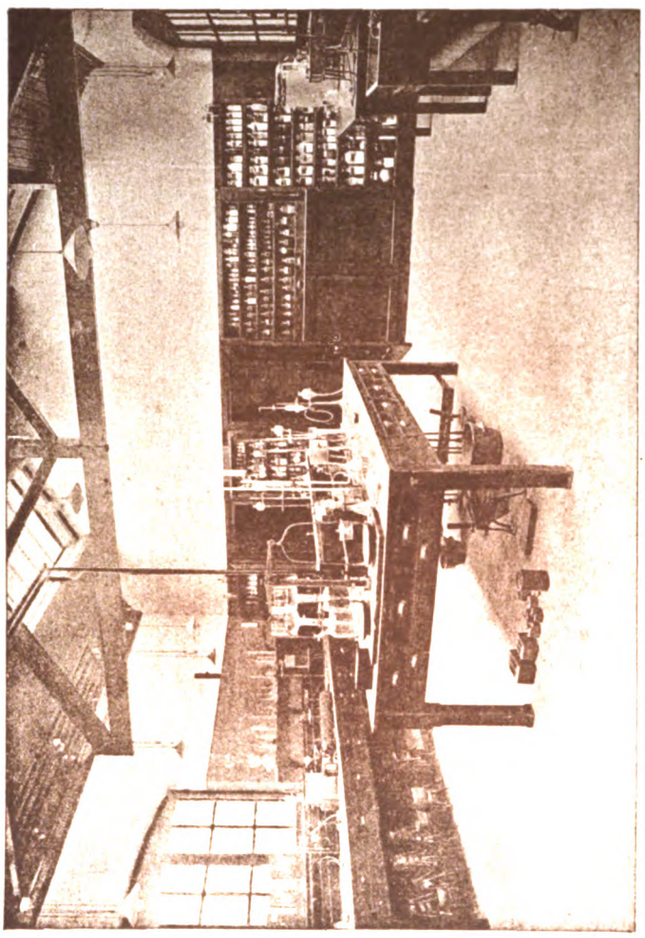
NOTES AND COMMENTS.

A CHARMING apology for tradition in architectural design and for the Orders as the expression of that tradition is Mr. PAUL WATERHOUSE's parable, "A Goodly Heritage," read before the Edinburgh Architectural Association. Yet whatever degree of regard or even of reverence we may hold for the works of the great past we in no way need to feel ourselves bound by the formulæ of PALLADIO, of VIGNOLA, or of CHAMBERS. In all ages, until the birth of the Italian Renaissance, architecture advanced by each man endeavouring to improve and sometimes succeeding to improve on the work of his immediate predecessor. We have lost touch in this twentieth century with our immediate predecessors; we must therefore go back to something and try to advance from the standpoint we select, remembering that originality does not necessarily consist, as some of the early exponents of l'Art Nouveau have seemed to imagine, in doing something so bizarre that no sane individual has ever done it before.

THE Special Commission on Concrete Aggregates appointed by the British Fire Prevention Committee has issued an interim report. This is not of much value, as it really only tells us what materials the Commission hopes to test, with the intimation that a final report cannot be expected before 1912. Even the provisional specifications lack the determining factors that would make them real definitions. The latest reports issued by the British Fire Prevention Committee deal with fire-extinguishing apparatus made by Messrs. AMMENTORP, of Copenhagen—firstly, as used to cope with burning masses of sundry varieties of inflammable material, and secondly, when used to extinguish burning petrol. In the latter case the extinguishers had a chemical effect upon the burning spirit leading to its extinction, but still left something to be desired in simplicity of operation and the density of the fumes created.

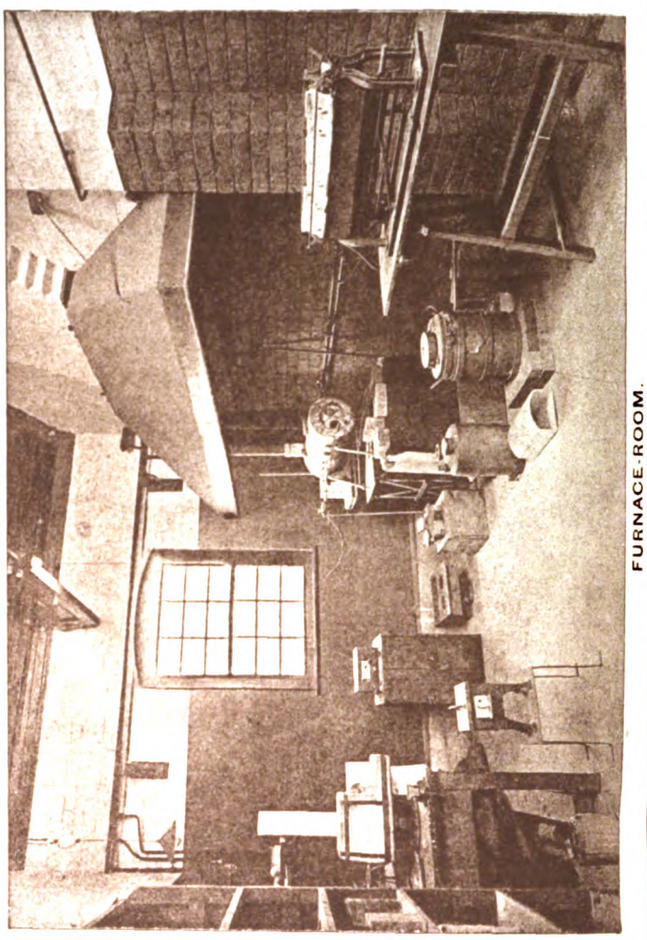
"LANDHAUS UND VILLA," published by the Westdeutsche Verlagsgesellschaft, of Wiesbaden, is illustrating a series of English designs for small country houses of the bungalow or cottage type, purchased by the German Emperor for the encouragement of the growing taste amongst the German middle-class householders for a little place in the country, an ideal home with a garden. The English architects whose designs are illustrated are Messrs. LAWSON & REYNOLDS and Mr. F. B. WADE. With the exception of Mr. WADE's half-timbered group of three cottages, which is capable of holding its own in any company, the examples selected are scarcely representative of the best English work in this direction, and suggest that their designers have been unduly hampered by considerations of cost. There is, however, a good deal of cleverness in the plans, notably in the one-storey bungalow by Messrs. LAWSON & REYNOLDS. The same publishers have issued also the first part of a guide-book for the prospective German investor in a house of his own with a garden, in lieu of a flat in town, entitled "Das eigene Heim und sein Garten." This compares the rent and accommodation of a town flat with that of the small country house, and shows how more accommodation and more comfort, as well as more healthy surroundings, can be obtained in the country at the same cost. It is worth noting, however, that the result is obtained only by limiting the return on capital to 4 per cent. One of Messrs. LAWSON & REYNOLDS's designs and one of Mr. WADE'S, as purchased by the Emperor, are given, and numerous designs by German architects, as well as photographs of executed buildings. In these picturesqueness of roof treatment is a strong point.

EVEN in Canada they are beginning to feel a failure in supply of building timber, and are suggesting the use of what they call "clay-lumber" or "terra-cotta lumber," meaning that class of clay goods in which brick-earth, mixed with sawdust, is burnt to produce a light and porous material. The potentialities of this material, of which we have at present only a few manufacturers in England, are no doubt considerable, but its general use as a complete substitute for timber is scarcely conceivable. Still, if the Canadians will use "clay-lumber" instead of wood for the walls of their houses, they may continue to spare us some of their pine for a longer period than would otherwise be possible.



As it frequently happens, and particularly in underpinning, that concrete foundations have to be laid in sections, the series of tests described in *The Engineering Record* as having been made at Lafayette College are of general interest. The tests were carried out to determine the strength of joints made between concrete laid at different times, and for this purpose beams of 5-feet span were tested under a transverse load, the load being applied 1 foot each way from the centre of the span. The following kinds of joints were tested:—Dovetail joints, the male part of the dovetail being 4 inches thick and the neck 3 inches thick; vertical joints roughened with a cold chisel; vertical joints reinforced with two ¾-inch round iron bars, 18 inches long, with nuts at each end; scarf joints, with a diagonal scarf one-third the length of the beam; similar joints scrubbed with oxalic acid; similar joints scrubbed with oxalic acid and treated with a paste of neat cement; step joints or parallel half and half scarfs. The reinforced joint proved to be the strongest joint tested, failure occurring not at the joint but beyond the reinforcement. The splayed scarf joints came next, those scrubbed with oxalic acid being a little stronger than those not scrubbed. The treating of the surface of the joint with a paste of neat cement, from the results of these tests, proves to be of but little value. The dovetail is the next strongest joint, but although stronger than the remaining kinds, seems to be much weaker than the splayed scarf joints. The vertical joints roughened and the step joints or parallel half and half scarfs were the weakest of all tested, and gave very low results.

MANY British architects would like to have a client like MARK TWAIN, who has lately had built for him a country house amongst the hills of Redding, Conn., which, the *American Architect* says, is characteristic in that, "until the house was finished, Mr. CLEMENS never saw the property which was bought for him, and refused to even examine the plans after his first general discussion with the architects, and never saw the house itself until he arrived one evening, with the servants installed, dinner served, and a box of his special cigars open in the billiard-room." Given a client who is able to tell his architect at the start what he wants, MARK TWAIN'S method of procedure is one that makes not only for the comfort of all concerned—client, architect, and builder—but for the right realisation of an artist's conception, economy of cost, and absence of extras. We know of one case where the client, having signed the contract, went abroad, and only returned when his building was finished—to his own and everyone else's satisfaction.



IN this country the use of concrete blocks for building is in its infancy. It is well, therefore, to know from American practice that curing the blocks by steam possesses many advantages. A steam-cured block is stated to be harder and stronger after twenty-four to thirty hours than one cured by sprinkling or spraying that is seven to ten days old. The colour of the blocks also is more uniform, regardless of the cement used, whether dark or light, and the steam gives them a lighter colour than it has been possible to obtain before. Another advantage is that the making and curing of the blocks is independent of the weather, and they can accordingly be made throughout winter frosts. The saving of time in curing admits of blocks being delivered in thirty-six hours from the receipt of orders.

THE "HAMBURG-AMERIKA LINIE" OFFICES, COCKSPUR STREET, S.W. GENERAL OFFICE.

ERECTED by the Disconto Gesellschaft, the main portion of the ground floor and basement of the Hamburg-Amerika Linie building, 14, 15 and 16 Cockspur Street, S.W., is now occupied by the H.A.L. for their enlarged offices, the remainder of the building being available for letting, to be divided into suites to tenants' requirements.

The building, which is of seven storeys and is of steel construction, stands on two different properties, and the main setting out has been unalterably determined by the conditions of the site and the requirements of the freeholders, and the exigencies of the light and air of the adjoining properties. The main shipping office is about 75 by 40 by 18 feet high, and is treated as one large room, the left-hand side devoted to the cabin and the right-hand to the tourist departments, with the cashier in the centre. Behind the cashier's department are the telephone cabinets and the typewriters.

In the basement beneath are the baggage-room with strong-room, goods lift to the back street, and extra office accommodation, lavatories, &c.

The manager's room in connection with the main office is approximately hexagonal in shape, and has a domed ceiling; the walls are white-painted panelling with a marble fireplace.

The main office ceiling is of modelled plaster of considerable scale and relief; the walls are panelled 11 feet high in choice Cuba mahogany, with specially selected veneers in the upper tier of carved panels. The dividing pilasters are inlaid with mother-of-pearl selected colouring, and the caps and bases of the secondary pilasters are of ormolu. The mahogany is of natural colour, polished but not stained, and is of golden yellow brown in colour.

There is a frieze of modelled plaster 6 feet deep above the panelling, the principal bays having ovals representing by figure composition the four continents. All the modelling has been carried out by Mr. SCHACHT from the architect's drawings, and the casting was executed by Mr. AUBREY. The central columns on the dividing line of the properties are of steel encased in concrete, and have been finished on the solid with superfine KEENE'S cement and polished by Mr. MINSHULL to a white marble face, the bases being finished black while the caps are gilded and in part burnished.

All the elaborate joinery, fittings, and furniture have been carried out by Messrs. WARING & GILLOW at their Hammersmith factory, from the architect's drawings, and Mr. RAYMOND has been responsible for the solid mahogany carving. The mother-of-pearl inlay was supplied and cut by Mr. LUCAS. The floor is of interlocked indiarubber, laid out in white bands with a solid black filling. Irish green marble from Connemara has been used in the fireplace in combination with Pavonnazzo and Italian brescia.

The large and elaborate chandeliers and other fittings, the ormolu and bronze screens, door-plates, &c., and the large wrought-iron screen and gates to the main entrance, and also the balcony railings have all been executed at Birmingham, from the architect's drawings, by the Birmingham Guild of Handicraft. The external bronze work, including the large panel with life-size figures over the entrance to the shipping office, was modelled by Mr. J. WENLOCK ROLLINS, and cast by Mr. BURTON, of Thames Ditton.

The sculpture in Portland stone on the façade comprises two large figures in half pediments, representing Germany and America, and a frieze of nine bas-relief panels across the curved lines of the bay windows, the subjects being the chief travel-stories of antiquity. These were all modelled and carved by Mr. W. B. FAGAN.

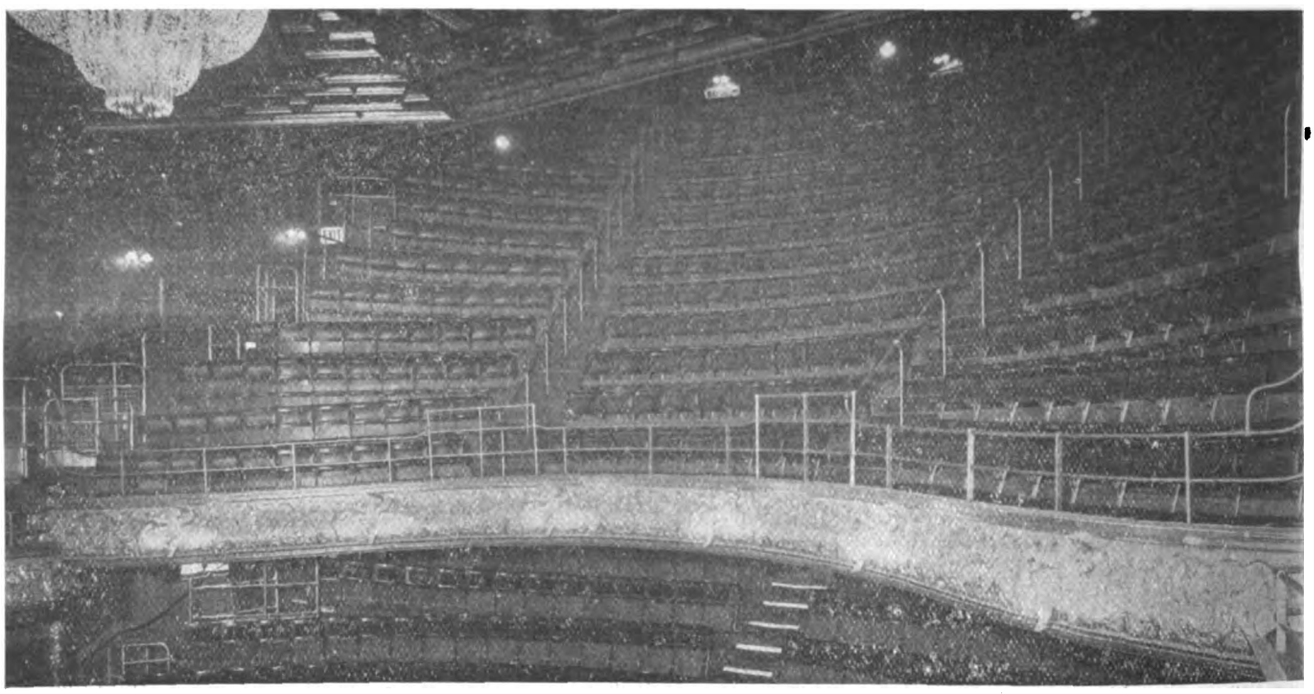
The work has been in progress about eighteen months, and the total cost approaches 50,000*l*.

The architects are Mr. ARTHUR T. BOLTON, A.R.I.B.A., and Messrs. STOCK, PAGE & STOCK, F.R.I.B.A., of Victoria Mansions, 28 Victoria Street, S.W.; and the quantities were taken out by Messrs. WIDNELL & TROLLOPE, surveyors, of Tothill Street, S.W. Mr. SANDALL has been clerk of works, Mr. BROOKS general foreman, and Mr. ROSCOE foreman in charge of all joinery and fittings for Messrs. WARING & GILLOW, the builders being the Waring-White Building Co., Ltd., the following firms being employed:—Portland masonry, the Bath Stone Firms; joinery (deal and hardwood), Messrs. WARING & GILLOW, Ltd.; mother-of-pearl inlay, Mr. LUCAS; steelwork, Messrs. M. T. SHAW & Co.; plastering, Messrs. WHEATER; paving, the Dolmite Company; plumbing and drainage, Messrs. DENT & HELLYER; electric wiring, Messrs. BEAVEN; heating, Messrs. NICHOLSON & Co.; electrical fittings, and Birmingham Guild; bronze screens and wrought-iron work, the Birmingham Guild; party wall, doors, and safes, Messrs. RATNER & Co.; grate interiors, Messrs. WRIGHT & Co.; hydraulic and electric lifts, Messrs. WAYGOOD & Co.; casements, Messrs. BURT & POTTS; plate glass, Messrs. WOOTON; show-cases, Messrs. STANLEY JONES & Co.; hardware, locks, staircase, handrails, &c., Messrs. HART, SON & PEARD; tiling and marble work, Messrs. VAN STRAATEN; mosaic floor vestibule, Messrs. BURKE & Co.; rubber flooring, the Peerless Rubber Floor Company; parquet floor, Messrs. TURPIN; asphalte flats, &c., Messrs. THOMAS FALDO & Co.; painting, &c., Messrs. WARING & GILLOW, Ltd.

THE CHARTERED BANK OF INDIA, AUSTRALIA AND CHINA, BISHOPSGATE STREET, E.C.

THE futile efforts to save Crosby Hall which were continued by persevering enthusiasts for more than six months were chronicled in our columns last week. The directors of the bank gave many weeks of grace before they commenced to pull down the historic building, and when that work had been completed they stored and preserved the remains at their own expense. The new premises erected on the site (which are to be opened to-morrow) have the grave dignity that might be looked for in a large bank. A detailed account of the strong-room, which is of special interest, is given elsewhere. The architects are Messrs. GORDON & GUNTON, Finsbury House, E.C.

NEW BUILDINGS, WALLSEND-ON-TYNE.



THIS building has been erected in Neptune Road, Wallsend-on-Tyne, for Messrs. the Thermal Syndicate, and contains entrance hall, large workshop, with battery room and store on ground floor, and laboratory, furnace room, and office, &c., on first floor. Externally the building is faced with red pressed facing bricks, with stone sills to windows, and the roof covered with small Welsh slates. The windows are wood casements, and the main cornice of wood painted white. The building was designed by Mr. EDWARD CRATNEY, of Wallsend and Newcastle (for Messrs. DAVIDSON & CRATNEY), and the contractor was Mr. J. MACHAIG, of Wallsend. The cost of the building, exclusive of fittings, was 700*l*.

ADDITIONS TO THE PALACE THEATRE.

LAST autumn the new amphitheatre at this house was opened to the public after entire reconstruction, as shown in our illustrations. When this theatre was built, two places, amphitheatre and gallery, formed the topmost tier, which were divided by a drop in the steppings of about 4 feet. For many years past these two parts had been used together, as amphitheatre, at one uniform price, but this drop in the steppings prevented intercommunication, and as the rows of the amphitheatre seats held from forty to sixty persons and the only access to or escape from these seats existed at the extreme ends of each row, they were most inconvenient. To form passages to the old amphitheatre walls existed cutting off the sides of the gallery; these walls have been entirely removed and the space so wasted has been utilised, thus enabling the formation of one large open circle of seats, numbering upwards

Digitized by Google

of 400 arranged in one even slope with regular steppings, each row being 2 feet 5 inches wide. Inlaid mahogany "tip-up" chairs have been fitted throughout, and dividing the tier into three sections two gangways have been formed through these seats, right from the front row to the back, and in addition to these the five front rows have separate exits into the gangways on both sides. Every seat without exception commands a good view of the whole stage. The procedure was to cut away completely the two front rows and all their steel construction, and then, to what was left, attach new constructional steel, arranged to different lines on plan and in height, projecting in parts some 2 feet farther forwards. On this and the old steel work was formed the new steppings to an entirely new shape of front line. Short lengths of the old amphitheatre have been left at the sides, forming small independent side galleries, the spaces behind which have been considerably raised and slightly projected and protected by strong iron railing forming well-sighted standing spaces with comfortable leaning rail. These alterations have raised the soffit underneath so much (about 18 inches) that combined with the changed shape of the line of front the circle below has been very greatly improved as to its view of the stage and its airiness. This (the first) circle has also

been considerably altered by the removal of the dwarf walls at sides and back and the substitution of ornamental iron barriers instead; the steps in the side gangways have also been so altered that each and all of the several rows of seating have ingress and egress at both ends. It also has been completely reseated with inlaid mahogany, velvet covered "tip-up" arm chairs, and the auditorium and its ceiling have been redecorated. The whole of the foregoing works were begun and finished in the record time of six weeks; the gallery was of necessity closed, but the whole of the remainder of the house, including the first circle, was open to the public as usual for eight performances a week. As the scaffolding necessary for the removal of the old gallery and the putting in the new steel work had to be removed and set up daily, great credit is due to Messrs. HY. LOVATT, Ltd., of Wolverhampton, the builders, and Messrs. RICHARD MORELAND & SONS, Ltd., of London, the constructional engineers. Mr. J. EMBLIN WALKER, of Uxbridge Road, W., was the architect, who had previously altered and reseated the stalls and royal circle and carried out the suggestions of the L.C.C., and who has now in hand the formation of a new suite of offices to accommodate the theatre staff. The whole of the reseating throughout the house has been done by Messrs. SHOOLBRED. The various alterations have added greatly to the comfort of the public and the safety of the building, and the management claim that "this theatre possesses the most comfortable and luxurious amphitheatre in the world."

BUILDINGS AND ENGINEERING WORKS BILL, 1909.

IN the last session of Parliament a Bill entitled the Building Operations and Engineering Works Bill was introduced by the Government, but did not reach the second reading stage owing to the necessity of giving precedence to other important measures which the Government had in hand. A similar Bill has been again introduced in the present session.

The London County Council's Parliamentary committee reported on the provisions of the Bill on November 24, 1908, when the undermentioned resolution was passed:—

"That an amendment of the Building Operations and Engineering Works Bill, 1908, be sought to provide that the work of inspection in the County of London under the Bill shall be carried out by the Home Office in lieu of the Council, or, that if the work of inspection be carried out by the Council, the expenses thereof shall either be reimbursed by His Majesty's Government, or met by fees to be paid by the builder or owner in the same manner as fees for supervision are now paid under the London Building Act, 1894."

In order to give effect to the above instruction a deputation, consisting of the chairman, Mr. Felix Cassel, K.C.; vice-chairman, Mr. Stuart Sankey; the chairman of the Building Act committee, Mr. Frank Goldsmith; and Mr. St. John Morrow, the chairman of the works committee, waited upon the Right Hon. Herbert Samuel, M.P., the Under Secretary of State for the Home Department, on February 16. Mr. Felix Cassel, K.C., stated on behalf of the deputation the views embodied in the report of November 24, 1908, and in the resolution above referred to.

Mr. Samuel, in reply, expressed his sympathy with the anxiety the Council felt in a proposal which was likely to lay additional charges upon it, but felt himself unable to consider any of the alterations asked for by the Council except an amendment to enable the Council to employ the district surveyors as inspectors to carry out the provisions proposed by the Bill.

The work of inspection under the Bill would be a matter of the utmost difficulty; buildings would have to be constantly inspected and the costs would be very great. The superintending architect has intimated that this cost would probably amount to at least 10,000*l.* a year, and the Parliamentary committee feels that this amount might be very largely exceeded.

The administration of the Factory Acts has hitherto been and is a national charge even so far as those Acts relate to buildings. The present Bill is, the committee argue, merely an extension of the principle of the Factory Acts, and they consider that the expense ought to be met out of the National Exchequer and not out of local rates. They therefore recommend:—

"That an amendment be sought in the Buildings and Engineering Works Bill, 1909, to provide that the expenses incurred in carrying out the provisions of the Bill be defrayed out of the National Exchequer and not out of the local rates as provided by the Bill."

ENGINEERING PLANT AT POOR-LAW INSTITUTIONS.

IN October 1907 Mr. John Burns, M.P., appointed Mr. A. Belmore Lowry, Mr. B. Taylor Kitchin, F.R.I.B.A., and Mr. H. Ross Hooper, M.Inst.C.E., as a departmental committee to inquire and report:—

(1) As to the machinery for lighting, heating, laundry and other purposes installed at some representative Poor-law institutions in London and elsewhere; as to any matters incidental to the running of the machinery, including the classes, numbers and remuneration of the officers employed; and as to the way in which Poor-law institutions compare in these respects with other places where such machinery is in use. (2) As to the most economical kinds of machinery which may be installed for these purposes at Poor-law institutions, regard being had to cost of running and efficiency of service as well as to cost of purchase, and to any special considerations attaching to particular classes of institutions; and (3) as to the classes, numbers and remuneration of the officers required, and as to any other matters incidental to efficient and economical administration where such machinery is in use.

In the course of their report, which has now been issued, the following valuable suggestions (which are applicable to other institutions besides those immediately dealt with) are given as to machinery and plant:—

General Considerations.—At many institutions the engineering arrangements have not been well designed. In many cases, also, plant in excess of requirements has been installed. Sometimes the explanation may be that the plant has been installed to provide for future developments. But even where this is so, the expediency of making such provision is doubtful, especially having regard to the increased cost of running plant which is larger than is required. The cost of generating electricity, for instance, may be very materially increased if the generating plant has to be run at a low load-factor. The special characteristics of an institution—such as its size, the purpose which it is to serve, the local conditions in regard to fuel, water and light—are factors of such importance in determining what plant should be installed as to render it impracticable for the most part to make any but tentative and conditional suggestions in respect of the kind of plant most suitable for Poor-law institutions. Moreover, in seeking to arrive at general conclusions the committee have found themselves seriously handicapped by the scarcity of continuous records at Poor-law institutions. In the absence of the material which records should supply for comparison of the efficiency and cost of different plants or systems, it is difficult to judge confidently of their relative advantages. It should also be recognised that, where improvements are so frequent as in engineering, no system of determining or supervising the installation of plant can be satisfactory which does not provide means for keeping abreast of the latest knowledge and experience. Subject to these necessary qualifications, however, the committee think it will be of service if they set out some of the conclusions on particular kinds of plant to which they have been led by the information gained during their investigations. As regards engineering plant generally, the committee have been strongly impressed with the desirability that it should be as simple as possible. There has undoubtedly been considerable waste in places, and the more elaborate the plant the more as a rule the opportunities for waste. So many different kinds of plant are required at a large institution that for economy and efficiency of working it is undesirable that there should be any undue elaboration of any part of the plant. Where inmates are employed in connection with the plant there is still greater reason why it should be as simple as possible.

Steam Boilers.—Lancashire or Cornish boilers are the most suitable types. They are simple in design and do not require special skill for their working or maintenance. Water-tube boilers are not recommended for institutions, and vertical boilers, while they may be suitable in certain cases, should not as a rule be adopted for permanent work. Where electrical generating plant is to be installed, high-pressure boilers, to work generally at not more than about 120 lb., will be necessary, but where steam is not required for electrical generating plant a higher pressure than about 70 lb. should ordinarily not be needed.

Mechanical Stokers.—Evidence was given by Mr. Hatch, engineer-in-chief to the Metropolitan Asylums Board, of economies effected at institutions under his supervision by the use of mechanical stokers. He stated that he had not in any case been able to reduce the staff by using these appliances, and that the economies had been effected by the use of cheaper fuel. He also commended the use of mechanical stokers as tending to reduce smoke. Local conditions are important in determining whether mechanical stokers will prove economical, and therefore they should not be adopted without thorough investigation. Where their use is desirable care is needed in the choice of a mechanical stoker adapted to the particular circumstances of the case and in proper regulation of its working. Further, with careless handling the expenditure on repairs and renewals may more than neutralise any pecuniary advantage which might otherwise be gained from the use of such appliances.

Economisers.—In order that the waste heat from the boilers may be utilised and the temperature of the feed-water be raised, it is desirable to instal an economiser where there is large central boiler plant. But the use of economisers should only be adopted on skilled advice and only at places where there are competent engineers to look after them. The quality and degree of hardness of the water to be used as boiler-feed should also be taken into account in determining whether an economiser should be installed.

Chimney Shafts.—In some instances which came under the notice of the committee there was not sufficient draught. Where the draught is insufficient there may be frequent trouble from smoke, or perhaps only a costly coal can be burnt, or mechanical draught has to be introduced. Chimneys should generally be built of sufficient size to admit of the burning of low-grade fuel without the use of mechanical draught.

Heating.—Large institutions are generally heated by hot water or low-pressure or atmospheric steam and by open fires or stoves. The hot-water system has much to commend it, and it was stated that, as compared with steam, on account of the lower temperature, there is less loss by radiation in transmission and less need of protecting pipes and radiators lest children or other persons be burnt; that joints, valves and fittings are less costly to maintain; that, especially when the hot water is supplied from a central source, the corrosive action of condensed water on iron pipes is largely avoided, as also is the risk of waste from steam traps; and that, for these reasons and others, the hot-water system was more economical and the life of the plant longer. It was asserted, on the other hand, that for some institutions steam is the less costly and that the readier control of temperature possible with a steam system is an advantage. The committee do not find it practicable to pronounce upon the relative merits of the different systems as applied to Poor-law institutions with the data they have been able to obtain. The want of adequate records at these institutions leaves them unable to form an approximate estimate of the relative cost of the different systems. They hope that the measures which they propose will gradually result in the accumulation of valuable information on this subject. More attention should be directed to the use of economical types of grates or stoves. Open fires are used more than should be necessary. In the main wards of infirmaries, for instance, there are often in use two or more large stoves, in addition to a system of heating by hot water or steam. Such duplication of heating necessarily adds to the cost of maintenance. Mechanical systems which combine heating and ventilation, while they may be adapted for some special cases, do not appear to be generally suitable for Poor-law institutions.

Calorifiers.—Calorifiers should be centralised as much as possible. They should be such as admit of being easily cleaned, especially those used for heating domestic hot water, since the deposit of scale rapidly reduces their efficiency. The necessity of facilities for cleaning is often overlooked at present. At one institution visited by the committee the calorifiers had just been cleaned for the first time in eight years and thick scale of adamantine hardness had to be removed. Calorifiers are sometimes so inconveniently placed that cleaning becomes a formidable process. It is also important that the use of steam in calorifiers should be carefully regulated. If this is not done, there may be considerable waste of steam and consequent increase in the consumption of coal.

Water Supply.—Many Poor-law institutions have their own artesian wells. Where potable water has been obtained at reasonable capital expenditure the cost of the supply from the well should ordinarily be less than the cost of a public supply, but at present records of cost are generally wanting. Rain water is very valuable for use in boilers and in the laundry, yet is frequently allowed to run to waste. It should always be collected when a clean supply can be obtained at small cost, and even when it is too dirty for use in the boilers or laundry it may be worth while to collect it for other purposes. Condensed water is even more

Digitized by Google

valuable than rain water, for it is not only soft, but also retains a high temperature, which can be given to cold water only at the expense of fuel and plant. Nevertheless, it is often allowed to pour into the drains, though a little thought would show that it would be as wise to pour away money. Any designing of building and plant which, unless there are very exceptional circumstances, does not provide for the return of condensed water is self-condemned. When the water contains oil or grease these must be separated before the water can be used again. When this is impracticable endeavour should be made to utilise the heat in the contaminated water before it is allowed to pass into the drains.

Exhaust Steam.—In connection with the use of condensed water may be mentioned that of exhaust steam. At many institutions visited by the committee a strong head of steam was blowing unharnessed to atmosphere, and frequently live steam was being raised for purposes for which the exhaust steam could have been used. With properly designed plant it should be possible to utilise practically all exhaust steam. In an institution where electricity is generated the exhaust from the engines may be sufficient to do all the heating required, including the heating of the domestic hot-water supply.

Water-softening.—Soft water is of great importance for boiler-feed and for use in the laundry. Rarely, however, should it be necessary to soften water if proper use is made of condensed and rain water. At one place visited by the committee, which had not long been built, extensive softening plant had been installed which would have been quite unnecessary had provision been made for the use of condensed and rain water. In the few cases where softening is advisable care should be taken that the apparatus is not larger than is necessary to deal with the water which it is essential to soften. It appears unnecessary as a rule to soften the water to be used for drinking and ordinary domestic purposes. The efficiency of water-softening plant requires more careful and regular testing than seems generally recognised at Poor-law institutions. Where the water used for boiler-feed is hard, chemical compounds are frequently used. The evidence received by the committee goes to show that the utility of such compounds varies unaccountably, and there is little doubt that at present much money is thrown away by want of proper discrimination in this matter. It is generally agreed that it is better to soften water before it is used as boiler-feed than to attempt to treat it inside the boilers. The committee were informed by one witness that he had found a special kind of graphite paint of remarkable efficiency in preventing the formation of scale even when the water was very hard, and that the use of boiler compounds and of water-softening plant was thus rendered unnecessary.

Lighting.—The number of institutions where gas is produced on the premises is small; those where electricity is generated are more numerous; but as a rule light is obtained from a public supply. Electric lighting is generally considered to have advantages over gas lighting for institutions, but a saving in cost for illuminating purposes alone is not usually counted among those advantages. Evidence was, however, submitted to the committee of economies effected in cost of lighting by the substitution of electricity for gas. It was not contended that light for light electricity was cheaper. The saving was attributed to the readier facilities for controlling the use of electricity. It appears to the committee, however, that much more care can be exercised in controlling the consumption of gas than is at present often the case, and that sufficient advantage has not been taken of the opportunities of economising by the use of incandescent mantles. On the whole, it does not seem to them that there is adequate evidence to justify the substitution of electricity for gas at institutions where gas is already in use. At new institutions the question is more open and depends largely on local conditions. Where electricity is installed consideration should be given to the use of metallic filament lamps, which consume much less current in proportion to the light given than carbon filament lamps.

Generation of Electricity.—The investigations of the committee have led them to the conclusion that when electricity can be obtained from an outside supply at a reasonable price the generation of electricity should not be undertaken. When the generation of electricity is undertaken more care is needed in determining what plant should be installed than has been exercised in the past. In many instances the plant is excessive. It is obvious that in these cases sufficient judgment was not exercised in installing the plant. The maximum load for an institution is not difficult to estimate. As already stated, excessive plant involves not only waste of capital, but also waste in cost of running, and the latter is even more serious than the former.

Battery.—The conditions at Poor-law institutions where there is generating plant frequently make the installation of a battery advisable, so as to avoid running the plant twenty-four hours a day. In determining whether a battery should be installed, it is important to consider (1) whether without a battery the generating plant would have to be run at a very low load-factor, thus materially increasing cost of generation; (2) whether the continuous running of the plant would necessitate increase in staff; and (3) whether with continuous running the exhaust steam could always be profitably used. Where a battery is installed care is needed that the size is in accordance with the requirements of the particular case. In some cases batteries have been discarded within a few years of installation. This suggests that in some of the instances at least they have not been properly handled. The management of a battery does not require very special skill. What is mainly needed is strict observance of the instructions of the makers. It is desirable that a contract, in terms free from ambiguity, should be entered into with the makers for the maintenance of any battery installed by them.

Laundry.—The investigations of the committee show that there is a tendency to instal excessive and too elaborate plant. The National Association of Workhouse Masters and Matrons gave evidence to the like effect. There also appears to be want of method in the use of machinery, two or more washing machines, for instance, being used at once where one would suffice, and much waste in the use of material. These defects are largely due to want of intelligent direction on the part of persons in control. Where sufficient inmate labour is available there should be little plant, and what there is should be as simple as possible. It seems probable that in this branch of work machinery has superseded hand labour to a greater extent than is necessary where inmate labour is available. As the National Association of Workhouse Masters and Matrons pointed out, with proper administration male inmates as well as female may be employed in the laundry. Separate infirmaries as a rule have their own laundries. The necessity for this practice is very doubtful, and it appears to the committee that the presumption should always be that the washing for the infirmary should be done, wholly or in part, at the workhouse. The committee were informed that difficulties arise when this plan is adopted, that complaints are made that articles are lost or not properly washed or not promptly returned. Such difficulties are not insurmountable and should not stand in the way of obvious economy. Separate laundries for officers are not infrequent. They are not necessary. Separate machines, if thought desirable, can be set aside for the officers' washing. A steam engine seems the most economical form of motive power for the laundry machinery, seeing that live steam has to be brought to the laundry for washing purposes. The exhaust steam from the engine can be utilised for heating water for the laundry and for drying clothes, and in some cases for other purposes as well. Care should be taken that not more machines are being driven at any time than are actually in use, a simple precaution which is not always taken. The laundry plant should be periodically inspected by the engineering staff, so that defects may be promptly remedied. With regard to the design of the laundry, one large room, with glazed partitions, where partitions are necessary, makes for economy, both in construction and administration.

Kitchen.—Apparatus of special design should not be necessary; the standard patterns and sizes should be sufficient. Too much use appears to be made of gas ranges and stoves and ovens, and not enough of ranges and ovens heated by coal or coke, which are generally more economical, especially ovens heated by coke. The officers responsible should be required to adopt the most economical means of cooking, and more systematic check is needed. For economy, ward kitchens should be restricted as much as possible. At present they undoubtedly add very materially to the cost of maintenance at many infirmaries. A small gas range or stove should usually be all that is required, provided that there is a supply of hot water.

Lifts.—There appears to be a tendency to put in too many electric or hydraulic lifts and to use them more than is necessary. It is not sufficiently recognised that every time a lift is used expense is incurred. The water used for hydraulic lifts is frequently allowed to run to waste.

Engineer's Workshop.—All ordinary engineering repairs at the larger Poor-law institutions should generally be done by the staff.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

The HON. SECRETARY said the fifth spring visit was fixed for March 13 to the Horseferry electricity generating station, Millbank, by permission of Mr. C. Stanley Peach.

It was also announced that an A.A. play, entitled "The Rise and Fall of Architecture," would be given on March 24 and 26 (smokers' night).

Messrs. D. A. Brodie and K. A. Cockrill were elected members.

On the motion of the PRESIDENT, a vote of condolence and sympathy was passed to the widow and family of the late Mr. Cole A. Adams. The deceased gentleman was president of the Association in 1883-5 and one of the trustees of the prize fund.

A cordial vote of thanks was passed to Mr. J. E. Franck for the gift of a drawing showing plans of English and foreign cathedrals on the comparative method.

Proposed House List, Session 1909-10.

President.—Mr. Henry Tanner, jun.

Vice-Presidents.—Messrs. F. Dare Clapham and C. Wontner Smith.

Ordinary Members of Council.—Messrs. G. C. Horsley, H. A. Hall, A. Keen, W. Cave, G. G. Scott, F. Winton Newman, Sir A. Brumwell Thomas, H. Field, P. W. Lovell, G. Drysdale, F. C. Eden, R. F. Atkinson, B. Greig, M. G. Pechell, H. Passmore, C. W. Ferrier, J. H. Squire (nine to be elected).

Hon. Treasurer.—Mr. Henry T. Hare.

Editor of "The Architectural Association Journal."—Mr. G. L. Elkington.

Hon. Librarian.—Mr. Percy May.

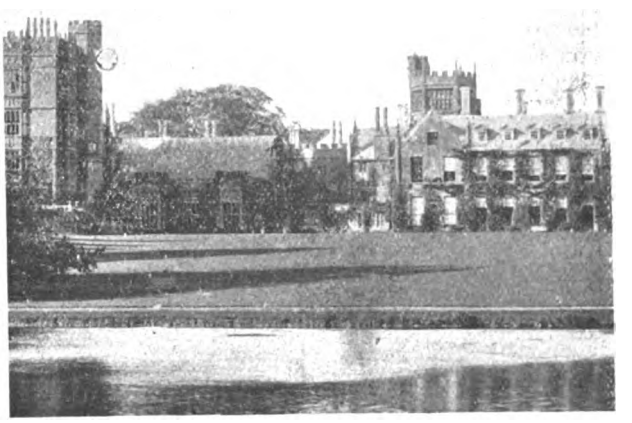
Hon. Secretaries.—Messrs. Maurice E. Webb and Edwin Gunn.

Hon. Assistant Librarians.—Messrs. A. J. Perrin and W. D. Cathcart.

Mr. JAMES WILLIAMS read a paper, illustrated by drawings and lantern slides, entitled—

George Devey and His Work.

He said:—At the outset I feel that some apology is due to you for the discursive nature of this paper, written as the various subjects occurred to one, but with a strong feeling



of inadequacy in doing anything like justice either to our good friend George Devey or to his beautiful work. At the same time it is a great pleasure to know that although he passed away many years ago, there remains a real appreciation of the man and his work, and if you only could have known him personally you would agree how natural and deserved that appreciation is.

George Devey was born in Dorset Place, Kentish Town, London, in the year 1820. His father was a solicitor practising in Ely Place, Holborn, where for some years he lived with his family. A man of the highest honour, he was greatly esteemed by his clients, both as friend and solicitor. Of sound judgment and marked ability in his profession, the son had a sincere regard for the memory of his father, and considered him an entirely unselfish, painstaking and devoted servant of his clients.

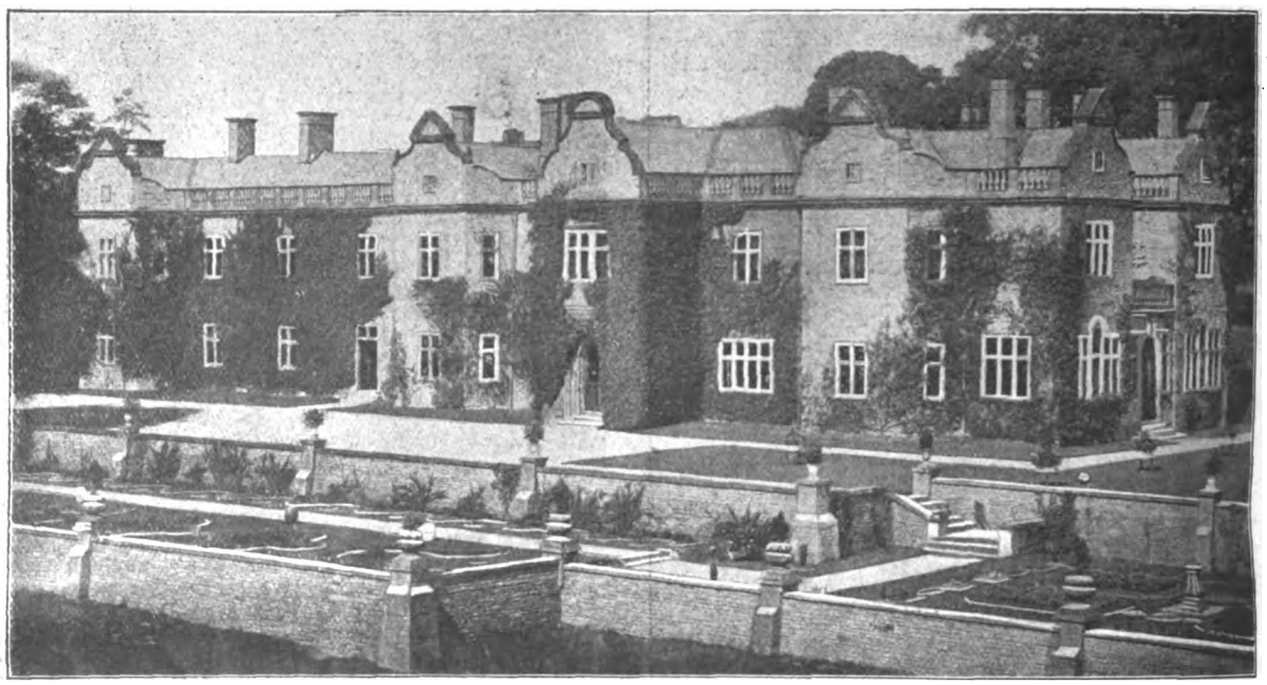
It was some extraordinary services, rendered to a needy client, that in the end secured for our friend an introduction to a distinguished man, resulting in the foundation of the young architect's practice.

One need hardly say that the early life and associations of such a man are always more or less interesting and important, having a good deal of influence on the formation of character. How much is involved in the fact that the father was a man of the highest honour. Let me mention as an illustration the case I have referred to as showing the atmosphere surrounding the early life of George Devey.

A gentleman, the reverse of rich, had been recommended to consult Mr. Frederick Devey, the solicitor (and father of our friend), with reference to the recovery of some property which had almost been given up as lost—partly on account of the lapse of time and the difficult tangle into which things had got, and partly because the client was poor. However, after endless investigation, with little chance of payment, the faithful solicitor succeeded in recovering a large estate, which put the needy client into very comfortable circumstances. His gratitude was great, and he took every opportunity of recommending and introducing George Devey wherever there was any chance for the young architect. As

a result Lord Hardinge became one of his first clients. This was the commencement of his professional work, and it was with natural pride that Mr. Devey would narrate the interesting and romantic story redounding so much to the honour and credit of his father.

In course of time the conscientious and painstaking work of the young architect over little things, together with his natural ability, refinement and attention to all the wishes of his client, so impressed the noble lord that he soon gave him more important commissions and went out of his way to find work for him. And he took a pride in showing his friends the drawings and sketches which he had asked the young architect to send him for that purpose. This circumstance, as well as the natural conviction which Mr.



Devey always held, led him to impress upon young men the importance of doing justice to and taking pains over the smallest commissions.

We know nothing of the childhood of George Devey, and he used modestly to say that he was never considered to be a very capable youth. From Kentish Town, when the children grew up, the family removed to Ely Place, Holborn, in order that the boys might go to King's College School. Mr. Devey seldom spoke of his schooldays, but the impression left is that the time there must have been somewhat irksome to anyone of his temperament. He was well grounded in Latin and French, which he could speak with fluency. After he left school we hear of serious discussions

Digitized by Google

as to whether he should follow the artist's or the architect's profession. He preferred the former, and from childhood had shown distinct ability in that direction. There is an impression that for a time he worked under J. S. Cotman and J. D. Harding, for whom he had a great regard, being influenced chiefly by Cotman. The earliest sketches about this period show great care in details, though they are somewhat formal according to the manner of that time. But his father and all his friends were against young Devey being an artist, for in the early part of the last century it was hardly thought of as respectable enough to be classed with the professions.

Eventually it was decided to article him to a Mr. Little, an architect and surveyor; at that time there were few men practising only as architects. Mr. Little appears to have had a small practice of a Classic character, and the young man must have had rather a dull time. We hear of surveyors' dilapidations and of the monotonous calculations involved in quantities. There are various detail drawings also showing conscientious work. Although all this sounds very uninteresting, especially to anyone of his taste and ability, we can at the same time quite believe that it was in some ways a valuable grounding. The most important thing he did in conjunction with his master was the designs for a new church—St. Mark's, Primrose Hill. Of these there were a number of drawings showing marked ability, especially when we think to what a low level architecture had sunk at that time, and it is the more remarkable when we remember that this work of his was almost before the Gothic revival had made any headway. In such an office and in such an age, how he acquired the true character, feeling and details of Gothic work is difficult to say, except by the unerring intuition of the artist and the revival then just starting, in which he must have been one of the first to participate.

Brantingham, Yorks.

After leaving Mr. Little he went on a Continental tour with his friend and fellow-pupil, Mr. Coutts Stone, going through France and Italy to Athens. In those days, when railways were few, it was a considerable undertaking, but it naturally allowed more time and convenience for observation and sketching. This our friends enjoyed to the full. There are not many drawings left of this tour, but what remain are exceptionally good, especially those made in Venice and Athens. They show, as do all his sketches, both in choice of subject, in composition and in refinement of execution, all the best characteristics of the true artist.

Although he would draw upon anything that came to hand, he was particular about paper and pencils.

There used to be in the Penshurst folio a beautiful little tinted drawing done on blotting paper, and there was an exquisite sketch of a hooded waggon, with six horses, done on a piece of the *Pall Mall Gazette* at six o'clock in the morning in Oxford Circus. Drawing and good music were things he never tired of, and the former was his chief resource in times of illness. He was never a strong man, though he enjoyed fairly good health, considering the active and arduous life involved with a large practice and works all over the country.

It was in the Penshurst country where his first business engagements commenced about 1850, and he continued going to and fro to the year of his death, as friend and architect. Lord De L'Isle was one of his first clients and remained all through to his decease. The restoration and repairs at Penshurst Castle were begun about 1850; the place had been very much neglected and the work was many years in hand, together with lodges and new cottages about the estate. Some of these have often been photographed as old buildings. The greater part of the work was done by an interesting and independent old character, an excellent type of the yeoman-farmer and builder combined, who used to talk to his lordship and Mr. Devey just as he talked to his men. He was well versed in the old methods and did good work. Here, too, were a house and various buildings done for James Nasmyth, of steam-hammer fame, who was a personal friend and always proud to show his visitors the boots he had kept when, as a workman, he tramped the country. Not far off is Hall Place, a large mansion and stables, built for the late Mr. Samuel Morley. Perhaps there are the most numerous examples of Mr. Devey's work in this county and the Aylesbury district, where a great variety of work was done on the Rothschilds' estates.

The journeys with Mr. Devey were always delightful. When the day's work was over he would saunter round an old town or village finding features, examining old buildings, making sketches or hunting up old furniture shops. He had a keen sense of humour, and the sparkling sallies of wit, cheery banter and quiet sarcasm often turned business into pleasure. He had a commanding and distinguished presence, with a generous and kindly manner, shown to workman and client alike, as befitted the gentleman he was.

In going over buildings, when things had gone wrong through carelessness, he would try gentle, or sometimes severe, sarcasm, as the case required; but when deception was met with, although he never lost his temper, his indigna-

Digitized by Google

tion made itself felt with all the more force. To a foreman making the lame excuse for indifferent work that it could never be seen, he said:—"What, not seen? I should be ashamed for the birds to see it." He never would hurry over inspections and instructions to foremen, and many were the hairbreadth escapes in catching the last train, and there were times when clerks of works and foremen wished that he had not been so devoted to his work. He always liked to call himself a working man, and often regretted that there was no badge for us to wear in common with all workmen, showing the sympathy he had with all honest labour. One reason he gave was that when out driving on business workpeople along the road might see that we were not out merely for pleasure. He had a wholesome contempt for all idle people of whatever station in life. He was fastidious and particular, but only in the way that all right-minded men are. He hated the dress-coat and Sabbatarian black, and liked homespuns and quiet-coloured shirts, not white linen. He delighted to draw carriages and spanking horses coming up to an entrance. He hated all shams and complications and loved simplicity. He was full of resources, ingenuity and invention. An old foreman, who for years followed him about on works, used to say with pride that you could never get him into a corner; he always fought his way out, and many were the difficult problems that he would save for solution. Mr. Devey had a great liking for the simple and natural modes of honest country work away from town influences—those sound, traditional ways of doing things that had descended from good men and old times. In the office everyone felt it a pleasure to work under him; his kindness was unfailing, and it was delightful to see the interest all had in looking at the revised plans and the dainty sketches for work done by him overnight.

(To be concluded.)

WESTMINSTER ABBEY AND FIRE PROTECTION.

THE architectural profession will always be the first to welcome any manifestation of a lively and intelligent public interest in our national monuments. It is perhaps inevitable that this awakening should sometimes display itself in ways of solicitude as well as in those of pride. One of the anxieties that must ever be present is the normal risk from fire; and it is on this danger that the imagination most easily fastens, even more readily than on any possible instability. Londoners may well have an instinctive terror of it, for their ancestors in the seventeenth century were struck down by the Great Fire, and since then the thought of its recurrence can never have entirely faded from their apprehension. The only too frequent conflagrations that are constantly bringing heavy loss to London must keep alive that dread.

In a recent article in *The Architect*, attention was drawn to the fact that some of the most important public buildings in the metropolis were not protected as fully as they might be if advantage was taken of the resources available, and in particular of the hydraulic mains which with their pressure of some 700 lb. per square inch lie at their very doors. Special stress was laid on the unprepared condition of St. Paul's, which is hemmed in by warehouses, filled for the most part with highly combustible materials, and whose dome from its great height needs more protection than can be ensured by the ordinary water supply.

This article aroused some interest. In our own issue for February 26 we published a letter from Mr. Killingworth Hedges, M.I.C.E., the hon. secretary of the Lightning Research Committee, in which comment was made in this connection about Westminster Abbey. The arrangements were condemned as "antiquated and deficient." Mr. Hedges described them as follows:—"The water supply for the hydrants in the triforium comes from a tank in the south-west tower, which has to be kept filled by a manual pump, worked by, say, a dozen men, and with relief, eighteen would be required. Suppose a fire was to take place in the night, there is probably not more than an hour's supply in the tank, and how the men are to be quickly assembled at a short notice is problematical."

In view of the gravity of the situation thus suggested the Dean and Chapter made an exception to their usual rule, and courteously invited us to send a representative to the Abbey, who could make a thorough inspection of the measures taken for coping with any outbreak of fire, and so be able to remove any wrong impression that might have been created by our correspondent's letter if his facts proved inaccurate. The offer was at once accepted, and our representative was met by Mr. Arthur G. Wallace, the assistant architect, who has been connected with the Abbey works for several years, and who had been deputed to give all possible information. Our cicerone spared no pains to demonstrate how seriously the Dean, Chapter, and everyone concerned regard their responsibility for protecting the historic building.

The letter we published is so far correct in its statement that there is a tank in the south-west tower which is filled by a hand-pump, and also that this tank does not contain more than an hour's supply. The tank, which is always kept filled, is actually 16 feet by 16 feet by 4 feet, and holds 6,000 gallons. But in the first place it is not necessary in order to refill it to achieve the difficult task of collecting a dozen or eighteen men to work at the manual pump. The tank certainly can be, and is, filled by means of that pump; but it is also directly connected with the water mains under the grass by the north-west tower, and can be filled directly from them. In the event of an outbreak a summons would be sent to the fire station, which is in close proximity to the Abbey, and the first action of the brigade officers would be to pump water from these mains into the tank, if the supply had become exhausted. Or water may be pumped from another hydrant direct into the pipes under the roof. Consequently there are, as a matter of fact, two unlimited supplies of water, either or both of which would be brought into use a quarter of an hour at the outside after the alarm was raised, and more probably within five minutes. It may here be mentioned that it is possible to throw a stream of water from the ground level on to the roof.

Obviously there would be little use in having all this water unless it was properly distributed throughout the Abbey. That this has been done as thoroughly as could be desired by the most exacting "protectionist" was forcibly brought home to us in a highly interesting perambulation in little-known parts of the Abbey, reached through unexpected doorways. It commenced by an ascent up a steep winding staircase to the triforium. Here there are twelve hydrants at regular intervals, with hose attached, and everything ready for instant use. In the north-west corner of the triforium is the manual pump to which reference has already been made, and which could be disconnected in case of an emergency. There is direct communication with the fire station by means of three telephones, one in the nave, another in the triforium, and the third in the roof. The greatest possibility of an outbreak, perhaps, lurks in the roof, with its timber framing. Here there are no less than sixteen hydrants, accessible either from inside the roof or from the gutters behind the parapet by means of movable covers. To afford greater facilities for immediate use the hose is not coiled, but is folded in lengths. These would produce a deluge of water directly they were brought into play.

Descending to the ground level we passed a double hydrant on the aisle roof looking down on Henry VII.'s Chapel. There are two hydrants in the nave, not including one especially provided to protect the organ, and a double hydrant in the centre of the ambulatory. There are hydrants in each tower, and also in the cloisters outside the chapter-house commanding the library, the deanery, and in fact, in every place where there would be any likelihood of their being of use. To make assurance doubly sure, there has recently been introduced into the main building a number of hand extinguishers. At night the Abbey is patrolled inside by a professional fireman, whose alertness is checked every fifteen minutes by a "tell-tale" clock, and outside by a watchman.

Cases are not unknown where the efficacy of elaborate protective measures have been nullified by carelessness arising from over-confidence. This can scarcely occur at Westminster Abbey. Every six months there is an inspection and report by officers from the London County Council Fire Brigade, and it would be difficult to imagine more trustworthy examiners. That this inspection and report is no empty routine is proved by the fact that the electric light fittings have been brought still more up to date in consequence of the recommendations made in a recent report, as to the best way to minimise their possible danger.

It will thus be seen from what we have said that the Dean and Chapter are fully alive to their onerous responsibility as custodians of this glorious national heirloom. Lovers of Westminster Abbey (and who is not one in a greater or less degree?) can rest assured that no precaution that may be considered necessary will be omitted. Gratitude is due to those who have done all this for the safe keeping of London's richest jewel.

ARCHITECTS' BENEVOLENT SOCIETY.

THE annual general meeting of this Society was held in the rooms of the Royal Institute of British Architects on Tuesday last, March 9, Mr. Ernest George (president) in the chair.

The Hon. Secretary (Mr. Percivall Currey) read the annual report of the Council, of which the following is an abstract:—

"The Council in submitting the fifty-ninth annual report have to record a year in which the demands made upon the Society have been exceptionally great. Ninety-nine applications for assistance were received, and in addition to the annuities allowed to eleven pensioners relief was afforded in eighty-eight cases. The income would not have been equal to dealing adequately with so many claims had not the Royal Institute of British Architects increased its annual contribution to 100*l.*, a sum further augmented at the end of the year by 25*l.* The total amount thus distributed in grants and pensions was 1,166*l.* 15*s.* 7*d.*

"Notwithstanding that the year has not been generally prosperous for architects, and that in consequence many subscriptions have been withdrawn or deferred, the Council have the satisfaction to report that there has been no diminution in this source of income, which amounted to 733*l.* 10*s.* Owing, however, to the urgency of the applications, the statement of accounts shows an excess of expenditure of 74*l.* 18*s.* 10*d.*, which will be reduced by the 25*l.* granted by the Institute, but not received at the close of the financial year.

"With regard to the capital account, the amount invested has been increased by the purchase of 150*l.* New Zealand 3 per cent. Inscribed stock. The total amount received in donations was 141*l.* 11*s.* 3*d.* Among the chief contributors were Mrs. Arthur Cates 50*l.*, Mr. John T. Christopher 22*l.* 15*s.*, Mr. Ernest George 21*l.*, and Mr. Arnold Mitchell 10*l.* 10*s.*

"The thanks of the Society are due to the T-Square Club, which contributed 6*l.* 3*s.* 9*d.*, being the proceeds of a concert, organised by Mr. W. J. H. Leverton, in aid of the Society.

"In view of the small number of subscribers—520—as compared with the number of practising architects, the Council would urge on all those interested in the welfare of their poorer brethren, or those dependent on them, the importance of exercising their personal influence in obtaining additional subscriptions.

"The thanks of the Society are due to the proprietors of *The Builder* and *The Architect* for granting space for free advertisements in their valuable journals."

The report and statement of accounts having been received and adopted, a vote of thanks, on the motion of Mr. Scamell, seconded by Mr. Brodie, was accorded to the retiring members of the Council, viz. Messrs. Walter Emden, Reginald St. A. Roumieu, H. Chatfeild Clarke, A. Saxon Snell, and Sir Henry Tanner.

The next business was the election of Council for the ensuing year. Mr. Macvicar Anderson moved, Mr. E. T. Hall seconded, and it was unanimously agreed that the following should be elected:—President, the President of the R.I.B.A.; Vice-Presidents, Messrs. Leonard Stokes, Thomas M. Rickman, and William Glover; Council, Messrs. Lacy W. Ridge, John T. Christopher, J. Douglass Mathews, Wm. Dunn, Henry T. Hare, Benjamin Ingelow, Henry Lovegrove, Rowland Plumbe, William Woodward (President of the Society of Architects), G. E. Bond, Arthur Ashbridge, Charles J. Blomfield, John Borrowman, C. R. Baker King, and Sir Charles A. Nicholson, Bart.

Votes of thanks were heartily accorded to Mr. Hilton Nash, the hon. treasurer, and Mr. Percivall Currey, the hon. secretary, who were both re-elected.

A discussion took place as to the advisability of having a dinner with the view of increasing the subscriptions, but no decision was come to, and the matter was allowed to stand over for further consideration.

The remainder of the formal business of the meeting comprised unanimous votes of thanks to the retiring auditors, Messrs. Greenop and Burke-Downing; also to the R.I.B.A. for use of rooms, and to the chairman, Mr. Ernest George.

The General Purposes Committee of the Marylebone Borough Council recommend, with a view to the provision of a suitable town hall, that an architect be engaged, at a cost not exceeding 100 guineas, to prepare a report and sketch plans relating to the suitability of various sites and the probable cost of erecting a new town hall.

GENERAL.

The Royal Institute of British Architects have now under consideration the conditions in the competition promoted by the London and South-Western Railway for a concert hall at Eastleigh, near Southampton, and the committee request the members to communicate with Mr. Ian MacAlister, secretary, before completing their design.

Mr. James Neale, F.R.I.B.A., F.S.A., of 10 Bloomsbury Square, W.C., architect and surveyor, left estate valued at 63,456*l.* gross, with net personalty 31,075*l.* He gave his drawings relating to the Cathedral or Abbey of St. Albans to the Dean and Chapter of St. Albans. His drawings relating to Canterbury or Canterbury Cathedral to the Dean and Chapter of Canterbury, and failing the acceptance of these bequests by either of these bodies, these drawings are left to the library of the Royal Institute of British Architects. And he bequeathed 1,000*l.* to the Royal Institute of British Architects for a travelling studentship in architecture, for the study and measuring of old buildings, or such other purposes as the Institution may decide.

Mr. William Milner Fawcett, F.R.I.B.A., F.S.A., of Cambridge, architect, formerly county surveyor for Cambridgeshire and surveyor for the diocese of Ely, left estate valued at 23,704*l.* gross, with net personalty 21,144*l.* He gave 100*l.* to his clerk, Arthur William Addison.

At a Public Meeting held at Burton-on-Trent last week it was agreed "that a personal memorial to Lord Burton should be erected to commemorate his long life of public service and open-handed generosity to the inhabitants of the town, and that the most suitable form of memorial is a full-sized statue, to be erected in King Edward Place." King Edward Place is the open space in front of the town hall, and in this immediate neighbourhood it is estimated that Lord Burton and his father expended between them 200,000*l.* on public buildings.

The St. James's Hall, Manchester, is shortly to be demolished. Plans are being prepared for an immense building which is to be erected on its site for the Calico Printers' Association, Ltd. The area of the site exceeds 6,000 square yards, and it is said that the new structure will be the second largest self-contained building in Manchester.

Mr. Jesse Horsfall, architect, Chapel Walks, Manchester, has prepared plans, which have been accepted by the Todmorden Town Council, for the erection of a secondary school on what is known as the Stile Estate. The estimated cost is 9,068*l.* The school is to accommodate 240 students.

A Memorial is to be erected in the Forbury Gardens Reading, on the site of the Abbey Church, as a memorial to King Henry I., who founded it in 1121 and who was buried there in 1136. The memorial has been designed by Mr. W. Ravenscroft, F.S.A., and consists of an Early English cross, in silver granite, 20 feet high, with mouldings appropriate to the Plantagenet period, and an inscription recording the burial of the king in the Abbey Church at Reading.

Mr. Joseph Holt, A.R.I.B.A., 9 Albert Square, Manchester has been appointed architect of the secondary school to be erected at Coalbrookdale by the Shropshire Education Authority on the usual terms.

The Members of the Edinburgh Architectural Association under the leadership of Mr. Ramsay Traquair, paid a visit to the Royal Scottish Museum in Chambers Street, Edinburgh, on Saturday. Important rearrangements have recently been carried out in the art collections of the museum. The great central hall is now devoted to architecture and the allied arts. The collection of Greek sculpture has been very much enriched, and now includes fine examples showing the growth of the style. The most important architectural examples are the interesting "Treasury of the Cnidians," from Delphi, and the great Ionic order from the Mausoleum. The progress of Mediæval art is represented by a series of casts from Celtic, Norman and Mediæval examples, including the fine figure of Christ from Amiens Cathedral. Examples of the Early Italian Renaissance are shown at the western end of the hall, and include a number of fine original examples, and some large models, including the "Paradise" of Isabella and Este. The furniture has now been rearranged in the north-western hall, and includes a large collection of wrought-iron work.

The Walsall Town Council on Monday agreed, by a majority of one vote, that in order to meet the increasing demand for current certain additions be made to the generating station, a new sub-station be provided in the centre of the town, and the system extended to Bloxwich, at an estimated total cost of 35,000*l.* Mechanical stokers are to be purchased at the electricity works at a cost of 2,143*l.*

The Architect.

THE WEEK.

MEMBERS who attended the meeting of the Royal Institute of British Architects on Monday last to hear the paper on "American Architecture," by Mr. FRANCIS S. SWALES, naturally derived their chief pleasure from the contemplation of the illustrations of the modern work of our American colleagues, and could not fail to be impressed with the marvellous improvement that has taken place since RICHARD MORRIS HUNT and HENRY HOBSON RICHARDSON demonstrated by their work the advantages of a Parisian training, and so set the fashion for the present generation of American architects. The excellence of modern American architecture is overwhelming evidence of the value of the French system of architectural education as carried on in the ateliers and Ecole des Beaux-Arts of Paris. It has been alleged that the academic character of French instruction would be prejudicial to the peculiar merits of our native architecture and inimical to the idiosyncrasy of the British artist, but our American cousins are sufficiently closely related for us to feel sure that what suits them will suit us, and that on both sides of the Atlantic there is sufficient verve and originality in our characters to ensure good results from training on Parisian lines, and to allay any fear that academic methods would depress rather than elevate the standard of our achievements. Modern American architecture, or at any rate the best of it, is excellent, because it is built upon the sure foundation of sound training. The American architectural student learns in Paris to design architecture, and it does not matter thereafter on what particular phase of style he proceeds to build his own work—Greek, Roman, Renaissance, or even Art Nouveau, he produces something that is architecture, that is art. So valuable has been felt the influence of the French system that the universities and other architectural training schools in the United States have remodelled to a large extent their own curricula to accord with it, and ateliers on the Parisian pattern have been established in several of the American cities. Some years ago Mr. F. T. BAGGALLAY and Mr. W. MILLARD started in London an atelier for architectural students, but the support they received from the young men of that day was not sufficiently encouraging to induce them to continue it. This, however, was scarcely on the Parisian model, although the instruction was excellent and highly beneficial to those who received it.

NORWEGIAN versus British granite is still a topic of the day, and Mr. MCKENNA is still being bombarded with questions in the House of Commons. On Monday last the First Lord's attention was called by Mr. WATT to a reported statement that a Scotch company had offered to supply the contractors for the Rosyth docks with Scotch granite at 13,000*l.* less than the contract price for the Scandinavian granite. We have been making some private inquiries, and have come to the conclusion that the state of the case is this:—The Norwegian quarry owners are more happily situated than British in that the granite quarries of Norway are close to deep water, and stone can be loaded practically from the quarry to the boat that is to convey the granite to Great Britain. Hence the Norwegians are primarily in a position to supply at less cost than the British. On the other hand, for various reasons that often operate in business matters, British quarry owners are sometimes prepared to supply granite at a lower price than the Norwegians. The quality of granite varies in Norway as it does in Britain; there is good and, comparatively, bad granite in both countries. The proper course therefore for architects, in their clients' interests, is to invite tenders from both British and Norwegian firms for any granite they may require before making up their mind which they will use. Price alone, however, must not be the only determinant factor. Samples must be obtained to ensure that all tenderers are on the same basis, and when the decision is made and the order given, care must be taken to see that the stone supplied is in accordance with the sample. To do this requires expert knowledge, and we are not all experts in granite. But there are at least two or three architects of good repute who have made a special study of building-stones and their examination, and who would, no doubt, be prepared to assist their less experienced colleagues with their advice.

THE church at Rome of San Crisogono in Trastevere is of some interest to Englishmen, connected as it is with the names of STEPHEN LANGTON, Archbishop of Canterbury, and Cardinal DA CREMA, Papal Legate in England. It has recently been discovered that beneath the present building is a lower church or crypt, as at San Clemente, but this older work is in this instance mainly outside the limits of the present church, by which it is only partly covered. There has therefore been a change of plan when the present church was built.

IT is an interesting psychological speculation that there may be something in common between wireless telegraphy and telepathy: that as invisible electric waves are transmitted through space by the medium of what, for want of better definition, is called ether, and may be arrested and recorded by suitable receivers, so thought, which is generally now considered to be connected with brain action—that is, activity of matter—may also be capable of initiating wave motion through the ether and of being arrested and recorded by suitable receivers. If this speculation could be reduced to a scientific fact we should then have an explanation of apparent plagiarism in art, often vehemently asserted on one side and as vehemently denied on the other, and could comprehend the phenomena of otherwise apparently inexplicable tendencies and waves of thought in art production. The very expression "waves of thought" which comes to one's mind quite naturally seems to uphold the speculation.

ARCHITECTS with clerical clients frequently find that vicars are oblivious to any necessity for a faculty when contemplating alterations to their churches, and pooh-pooh the idea if their architect suggests such a thing. It it well therefore to bear in mind the judgment given by Dr. TRISTRAM in the Consistory Court held at St. Paul's Cathedral on Friday last, when the Vicar of St. Andrew's, Haverstock Hill, was condemned in costs because he was held to be wrong in making certain alterations in the chancel of the church without a faculty, even if he had the consent of the parishioners. As it is extremely difficult to make alterations, even though they be obvious improvements, to existing arrangements without treading on somebody's corns, architects should always strongly advise an application for a faculty. Nine times out of ten one may never have any trouble resulting from making alterations without a faculty, but the tenth time some cantankerous parishioner—he need not be even an attendant at the church—may bring down the heavy hand of the law, to the vexation and annoyance of the architect and his client, to say nothing of pecuniary loss. It is but fair to note that the vicar in this particular instance feels himself aggrieved, and has expressed his intention of appealing against the Chancellor's decision. But ecclesiastical law is strict and not easy of comprehension by the non-legal mind.

WE are not singular in England in adopting the latest phase of the Renaissance for the motif of twentieth-century architectural design. The "Barock" period in Germany produced some very remarkable works, and it is not therefore astonishing to find modern German architects occasionally utilising their own eighteenth-century work for the basis of their designs. The current number of *Berliner Architekturwelt* illustrates a good example of this treatment in the Viktoria club-house in Berlin by Herr WILHELM WALTHER. Exception might perhaps be taken to some parts of the design; it is always easy to find fault, but there is far more that is admirable and pregnant with valuable suggestion.

ETHICS OF PROFESSIONAL PRACTICE.

MOST architectural practitioners are we doubt not desirous of carrying on their business in a manner that shall be fair to their colleagues at the same time that it is advantageous to themselves, and also that they themselves may be treated as fairly as they would wish to treat others. There are many practices that arise in carrying on the business of an architect as to which there can be no question of their rightness or wrongness, but there are others as to which there may be legitimate doubt, and still others which though they cannot be stigmatised as wrong may yet possibly be objectionable as transgressions of good form or etiquette in professional conduct.

It would seem therefore to be desirable that a code of professional etiquette should be prepared and promulgated by the Royal Institute to form the standard of conduct to be observed by all decently minded practising architects. Illicit commissions or bribes are unmistakably branded by the statute law, as well as by the declaration that every Fellow and Associate of the Royal Institute has to sign on his election, but beyond this there is very little guidance for the young practitioner. The Council of the Royal Institute has indeed started a code, but at present this only contains two items, and these quite minor points of one question, professional advertising. It is authoritatively laid down that it is bad form for an Institute member to display his name on a board announcing that he is the architect of a building in course of erection, but quite right for him to leave his name permanently on the completed structure as a signature. It is also not etiquette for a member of the Royal Institute to style himself other than "architect" or "architect and surveyor." We presume that this does not bar the use of the letters "F.R.I.B.A." and "A.R.I.B.A." which are empowered by the Charter, but is directed against the coupling of the profession of an architect with that of an auctioneer, estate agent, or undertaker. It is quite true that some prominent members of the Royal Institute have made a considerable part of their income by acting as estate agents, but it is clearly undesirable that this should be publicly thought to be an ordinary or usual function of an architect.

But there are many other varieties of professional advertising that require to be distinguished as good or bad form. Professor Donaldson, than whom probably no more high-minded architect ever existed, laid it down that it is perfectly legitimate and consistent with good taste for an architect to make the fullest use of the professional journals to make himself and his work known; in plain words, to advertise. How far is it consistent with professional etiquette for an architect to illustrate his executed works or his purely speculative designs in the non-professional Press? If the practice is allowable at all it is capable of indefinite extension, and this is, it seems to us, a question that the Council of the Royal Institute ought to consider and determine.

The authority of eminent examples appears to justify the publication of books by architects illustrating buildings erected from their designs, whether monographs or polygraphs. To what extent is the presentation of copies allowable? It would be unreasonable to debar a man from presenting copies to his personal friends and relations. Then surely he might do so to his acquaintances, and why not to his friends' acquaintances until the circle expanded so far that there would be little distinction from the manufacturer's issue of a catalogue? Where is the line to be drawn? Another question for the Council to determine. Again if executed designs may be thus illustrated, should non-executed designs be debarred? For many architects the designs they are capable of making for any particular building are far superior to those they have the opportunity of carrying into execution. Painters and sculptors are not prevented from showing the best that is in them because they have not received a commission to produce it. Why should an architect be fettered? The Royal Academy hangs in its architectural room designs that are never intended to be translated into bricks and mortar. When an architect has received a commission to design a building to cost say 5,000*l.*, is there any objection to his making a design for the same building that would cost 20,000*l.* and showing it at the Royal Academy or in the pages of the professional Press? There is very good precedent for the practice.

The production of literature dealing with technical subjects is recognised as a legitimate method of advertising in such strictly regulated professions as medicine and law, and there cannot be any reasonable objection to the same practice in architecture. Now it is a custom frequently followed by book publishers to include advertisements, sometimes cognate to the subject of the book and sometimes not. How far is such procedure admissible in books written by professional men?

One form of professional advertising that is now almost if not quite obsolete is the publication of business cards in the advertisement columns of the Press. At one time this was quite common in American papers, and it has been seen in some of our own provincial Press, but nowadays it is, as far as our observation goes, limited to naval architects. It is a form of advertising that is of very little real value and distinctly unworthy of a dignified profession.

Advertising is not the only department of professional practice that requires a code of etiquette or ethics. The solicitation of work or touting surely needs regulation or restriction. The exalted ideal of a profession excludes touting in any shape or form; the professional man must wait till he is consulted, and the profession of architecture can hardly expect to be publicly recognised as on the same plane with medicine and law, unless the professional ideal is maintained in the former at least as strictly as in the latter professions. The contention that architecture is an art and not a profession is not improbably weighted with this consideration. A painter or a sculptor produces his goods and offers them in *marché overt*, and if architecture is an art and not a profession the architect can do likewise. If this is to be our position let it be openly recognised all round. If the architect R.A. may follow the example of his compeers who are painters and sculptors it is unreasonable that the country practitioner or the youthful A.R.I.B.A. should be bound in this respect by notions of professional etiquette. But we must accept the consequences. The painter R.A. who offers his picture for sale on the walls of the Academy is as much a tradesman as Liberty or Elkington, and the low esteem in which we learn from Plutarch, Lucian, and other writers the ancients held the social position of artists as renowned as Pheidias and Polycleitos must be accepted by us also. Tradesmen employ travellers and canvassers. May architects do the same? If so to what extent? Excellent architectural businesses have been established by the help of the tactful commercial push of a wife, a cousin, or an aunt. If such assistance from a relation is legitimate, why not that of a friend or that of an employée? Is any line to be drawn, and if so where?

Mr. Ernest George, in one of his presidential addresses this session, hinted that the young architect might build up his business by tactful suggestions to possible clients. Touting, therefore—for such suggestions must be admitted to be a form of touting—has high sanction as legitimate in the business of architecture. Is there to be any limitation and if so what? It might be said that an architect should not tout a total stranger, but acquaintances are easily made and some sort of an introduction is readily obtained. One thing certainly ought to be decreed, that no architect should tout another man's client. And this brings us to another point. It is not an unknown thing for an architect to take advantage of his position, official or otherwise, to oust a brother practitioner from his job. This behaviour should certainly find reprobation in any code of professional ethics.

Another question that requires regulation by code is the position of an honorary architect. Is an architect who poses as "honorary" justified in demanding or accepting payment for expenses, either directly from the

Digitized by Google

committee—there is usually a committee when an honorary architect's services are accepted—or indirectly through the contractor? There have been cases where an honorary architect's expenses have amounted to a large proportion of the customary full charges, and it would have been possibly more honourable for the architect to have charged the usual commission and made a donation to the funds, representing the amount by which he really did benefit the undertaking. And this brings us to the question of 5 per cent. Is it unprofessional to accept less or to charge more? We think not, but the position should be clearly defined by the Royal Institute. Trades unionism does not prevail in architecture, and no one can say that every man's services and abilities are of equal value; there cannot rightly, therefore, be one universal scale of pay.

The participation of architects in trading concerns is a somewhat difficult question. How far may an architect be financially interested in the business of those who work for or supply goods to his client under his supervision? An able young craftsman is setting up in business. Would it be wrong for an architect to advance him capital and give him work? It would very likely be necessary for the safety of the capital that the architect should retain a controlling interest in the business—should be, in fact, a partner of the craftsman. How far would this be right or wrong?

Such are some of the points that occur to us as not only worthy of consideration but desirable of elucidation in a code of professional practice, for the provision of which the Council of the Royal Institute of British Architects is the only authority that could be recognised.

STEELWORK.—VII.

By C. V. CHILDS, A.M.I.C.E.

THE plate girder is the girder par excellence for heavy loads and long spans. It can be built up to carry anything that is ever likely to be required in the way of steelwork for buildings. The limit of size is more a question of delivery to and erection at, the site than anything else. Probably the largest that have been erected in London are the curved girders carrying the galleries at the Coliseum, weighing as much as 60 tons each, with a span of 100 feet. The form of these girders is exceptional, as they are not only curved in plan to follow the curve of the balcony, but in elevation as well. In fact, they partake of the arch probably almost as much as of the girder, and are prevented from turning over sideways, as they are naturally inclined to do owing to their shape, by the strength of the connections of the floor girders, which mutually support, and are supported by the plate girder. The girders exceeded the limit mentioned above, and were constructed and rivetted together at the site, supported on falsework.

There is one fault to be found with these girders, and not with these alone, but in other cases also, and that is the excessive thickness of the flange plates; the total thickness of all the plates being as much as 8 inches. Half this amount should be the maximum in total thickness. Flange plates are useless unless their compressive and tensile stresses can be linked together by means of the rivets that transmit these stresses one to the other through the medium of the web plates. Apart from the difficulty of upsetting the shanks of the rivets, while they are being driven, so that they fully fill the holes, there is the fact that the rivets themselves would fail by bending on account of their length, instead of shearing across their section; a slight amount of bending would relieve the outer flange plates of all their stress. Even in the design of the pin, for the typical American pin-connected bridge, the bending moment is of far greater importance than the shear on its cross-sectional area. How much more is this the case, where the rivets are practically cantilevers, anchored only by the bearing of their heads on the surface of the flange angles. It may be mentioned, by the way, that the writer once heard in America, that the reason why pin-connected bridges did not come into favour in English practice was on account of the above-mentioned reason. One of the few examples of the pin-connected bridge in England is the Charing Cross bridge; and it was said that the pins had been designed for shear only, the bending moment not having been taken into consideration; consequently trouble had arisen, and brought disfavour on this type of bridge. Whether this is true or not, it certainly seems a pity that the pin-connected type has practically disappeared in English design, if only for the sake of its being more graceful in appearance than that of the rivetted connection bridge.

Returning to the consideration of the plate girder, especially the question of the rivetting, as it is in this respect the workmanship is more generally at fault; it may often be noticed that the size of the flange plates seems to be out of all proportion to that of the flange angles, these latter being so small as to allow of only one row of rivets to connect them to the web plate; even though the area of the flange plates may be considerable and their width such that it is necessary to forge the ends of the stiffeners to form knee braces, so that these not only stiffen the web, but also the flange plates against buckling. It would be better construction to increase the sizes of the flange angles, to allow of a double row of rivets and dispense with the forged end of the stiffeners; even if, by so doing, it means an additional web plate, where wide flange plates are required.

The shearing value of the rivets connecting the flange angles to the web, for a length of the girder equal to its depth, should, of course, be the same as the shear in such a panel; but it is questionable whether this rule is as strictly adhered to as it should be; in plate girders, carrying heavy loads on short spans, it is often rather a troublesome matter to arrange for the requisite number of rivets.

For girders of similar cross sections, with loads similarly disposed, the pitch of the rivets required for short spans is smaller than that for the longer spans. The safe load on a girder is inversely proportional to the span; the safe load regulates the amount of the shear, which in turn regulates the pitch of the rivets; consequently, for one girder, that is half the span of another of like section, the rivets should be spaced one-half the distance apart. This practically amounts to the total number of rivets being alike in either case.

It is seldom that any difference is made in the flange areas between that of the compression or tension flanges; the area of the rivet holes that are deducted from the tension flange provides a slight additional strength for the compression flange, which even then is probably the weaker member of the two, owing to its being in the nature of a stanchion, of a length equal to the span. In large plate girders, such as for through bridges, it becomes necessary to take this into account, by providing lateral braces to prevent any danger of the compression flange buckling. If the designer desires to be especially economical, it is a usual practice to allow one-sixth of the area of the web plate, as a portion of the required flange area; one-sixth the area multiplied by the depth being equivalent to the moment of resistance of the plate; the web plate has, however, usually quite enough to do without calling upon it to perform other duties.

The size of the web plate, if designed solely to resist the shear, is, especially for short spans, more in danger of buckling under its compressive stresses than in failing in any other way; hence the necessity for the stiffeners—tees, angles or channels, as the case may be. For excessively heavy loading, and where two or more web plates are used, it is well to connect the webs together with diaphragms, such as channels or joists; these make very efficient stiffeners for the web plates.

To determine whether stiffeners are required, the following table, which may save the designer the trouble of calculating the strength of the web plates as against buckling, may be found convenient.

The amounts given in tons are the limiting values of the shear, within which stiffeners are unnecessary. With these are incorporated tables showing the areas, in square inches, of two rivet holes of different diameters in plates of various thicknesses.

Web Plate. Depth in Inches.	Thickness.

The chief trouble with regard to plate girders is in the matter of delivery; unfortunately they are apt to be very slow in appearing at the site. The reason for this is not so much the fault of the constructional workshops as of the rolling mills, the difficulty being to obtain the plates from the mills. What is needed is that some enterprising manufacturer should lay down a universal plate mill, which would obviate the delay now caused by waiting for the rolls to be put in for the flats required, or for the larger plates to be first sheared, and afterwards planed, to the required dimensions. For girders used in buildings planing the edges of the plates is an unnecessary luxury, if rolled flats or universal mill plates could be obtained. The universal mill is one in which four vertical rolls are employed for rolling the edges of the plates, whilst it is also passing through the horizontal rolls that reduce it down to the required thickness.

There is a very fine example of this type of mill at the Homestead works of the Carnegie Steel Company; this mill can roll plates of any desired width or thickness usual in constructional work, and saves all the waste of time that is necessitated by changing the rolls for rolling flats of different widths.

The compound is the most useful of all built-up forms of girders in building work. Strangely enough it is but seldom used in American practice; this being due to the reason already stated in regard to built-up stanchions, viz. the existence of the "Beam pool," when structural work was first being developed in America; the joist section was avoided as much as possible owing to its being more expensive than plates or angles. The reverse of this is the case in England; hence it is more economical to use compounds in place of plate girders, wherever practicable. Perhaps another reason why compounds are not more used in America is that it is the usual practice there for the holes in this class of work to be punched, and punching holes in the flanges of a joist, especially if on only one side of the joist, causes the joist to become curved, and necessitates its being straightened before the cover plates can be rivetted on, whereas in English shops it is customary to drill the holes in all compounds, in order to save this trouble, the works being equipped with batteries of radial drills to deal specially with this class of work. Moreover, English structural work is on the whole of a heavier class than American, and the need for compounds is far greater.

Compound girders can be made very strong in comparison with their depth, which is a desirable quality where they are used as floor girders and the maximum amount of headroom is required; one thing must not be forgotten, and that is that the rivet heads have to be taken into account in their over-all depth; an 18 inch by 7 inch joist and a 16 inch by 8 inch compound may be equal in strength; the compound appears to save two inches in depth, whereas with the rivet heads its over-all depth will be but half an inch less than that of the joist. This is one of those little pitfalls that so often occur and that may cause a client to pay the extra cost of the compound, thinking thereby to save 2 inches in the depth of the casing of the girder. On paper, the compound certainly looks less in depth than the joist, but in reality this is almost fictitious.

This question of the depth of the girders breaking down beneath the level of the ceiling is one of the chief bugbears of the steelwork designer; he is continually having to decide nice points of difference between economy on the one hand and appearances on the other hand. Naturally architects, or their clients, do not like to see their ceilings spoilt by ill-placed cornices encasing the girders; and yet sometimes architects set the designer some severe problems in this respect, on the assumption that steelwork can accomplish anything nowadays. In ordinary office buildings or hotels where the rooms are moderate in size the main girders can usually be hidden in the cornices of the ceilings, adjoining the partition walls; the breaks in the ceilings can be more or less confined to the passages. In large rooms, however, care has to be taken to make the cornices fit in with some feature of the room, such as a pier in the external wall. On the other hand, amongst some features to be avoided are cornices running into chimney breasts or over window heads, as these are very unsightly.

All this goes to show that the steelwork designer's influence may affect the general appearance of a building, even in its internal decorations.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last, at Conduit Street, W., Mr. Ernest George, president, in the chair.

Mr. ALEXANDER GRAHAM, hon. secretary, announced the decease of M. Alfred Nicolas Normand, a distinguished French honorary corresponding member of the Institute, who held the Prix de Rome about 1850.

Mr. FRANCIS S. SWALES read a paper illustrated by lantern views entitled –

American Architecture.

The Lecturer referred almost exclusively to work at Washington, and dealt at great length with the location and foundation of that city on the river Potomac. Philadelphia, New York, Baltimore and other large towns had urged their claims to be made the seat of the national Government, but rivalry was so keen between those cities, and political partisanship so bitter, that a ballot even gave no results. Finally an Act was passed conferring upon President Washington the sole power to select a Federal territory "*not* exceeding ten miles square on the river Potomac . . . for the permanent seat of the Government of the United States." This Act authorised him to have the site surveyed and planned, and to proceed with the construction of certain works and buildings. The President therefore appointed three commissioners to supervise the development of the adopted site, Major Ellicott to survey the territory, Major L'Enfant to plan the city, and Thomas Jefferson, then Secretary of State, to confer with them. That the latter was qualified to act as one of the Commissioners cannot be doubted, for later in life and after he had retired from office at the expiration of his term as President of the United States, he designed among other works the fine group of buildings for the University of Virginia, and his own house, Monticello. L'Enfant's plan approved by Washington and Jefferson, and adopted by Congress in 1791, was during the author's lifetime carried out only so far as securing sites for the principal Government buildings, cutting down trees and making a few of the principal roads. The site once chosen, all available land had been bought up by speculators, who held it at high prices, and thus retarded the growth of the city. In 1792 a competition was held to procure a design for the Capitol, which was L'Enfant's designation of the Federal house. Sixteen designs were submitted, but none were regarded as worthy of serious consideration. Shortly afterwards a French architect, Stephen Hallett, of New York, submitted a design to the Commissioners, which met with general approval, and he was asked to journey to Washington. About the same time Dr. Wm. Thornton, a Philadelphia physician and amateur architect, who had studied in Paris, presented an elaborate coloured design to President Washington, who was so impressed that he asked the Commissioners to adopt it in place of that submitted by Hallett. The latter declared that Thornton had stolen some of his rough sketches, and merely elaborated upon them. This charge Thornton vigorously denied, and the premium originally offered for a design was awarded to him. Thornton, however, was not considered to be competent to carry out the work, and Hallett was made supervising architect. He was ultimately dismissed, being succeeded by George Hadfield, an Englishman. A competition was next held for the President's house, and this was won, and the work carried through by James Hoban, an Irishman, who had been clerk of works under Hallett, and who afterwards succeeded Hadfield. He also completed the north wing of the Hallett-

Digitized by Google

Thornton design for the Capitol. Three years later Benjamin Latrobe was appointed to construct the south wing. In 1814 the British troops having taken the city of Washington, burned the Capitol, the President's house, and other public buildings. Latrobe afterwards restored the Capitol, and to him is due the credit of designing the former House of Representatives, now known as Statuary Hall, and the old Senate Chamber. Charles Bulfinch, of Boston, succeeded him. He designed the hall of the old Library of Congress, which formed the projecting central feature of the west front, modified Latrobe's design for the dome, and in 1827 reported the Capitol was finished, and for twenty years nothing further was done to it.

In 1833 the old building of the Treasury was destroyed by fire and Mills was appointed to design a new one. He took so long deciding upon the site that President Jackson, a soldier by profession, lost patience, and meeting the architect just outside the President's house one morning, he planted his cane at the spot where he was standing, and said, "Here, right here, is where I want the corner-stone laid." The selection of this site was a serious blunder, and a blot on L'Enfant's plan. To President Jackson the lecturer attributed the beginning of the appointment of army engineers to construct Government buildings. As Washington and Jefferson had appointed engineers and architects, men of their own professions, Jackson felt that he should follow their precedent by appointing others from his. On the other hand his action was partially justified by the dearth of good architects. The commercial undertakings everywhere called loudly for the help of all the brains in the country; there were doubtless plenty of opportunities for architects who could have shown themselves competent to grapple with the problems of the times, but if a design for a church was required, a Greek-Ionic temple was submitted, if a railway station a Greek-Doric temple was considered suitable by the so denominated architects. In 1850 important extensions to the Capitol became necessary, and Thomas U. Walter, of Philadelphia, was entrusted with the task, who carried it through to completion. He treated the scheme boldly and simply, leaving the plan of the centre block as he found it, and adding two great wings, making a three-part composition. His work, it was suggested, represented the last phase in American architecture of the past.

The architecture of the present in the United States, continued the lecturer, might be said to begin with R. Morris Hunt, who returned from Paris in 1855. Hunt had been for ten years a student in the Ecole des Beaux-Arts, and he had worked under Lefuel and Visconti upon the construction of the extensions of the Louvre, carried out during the Second Empire. In America he saw the endeavour to resuscitate Gothic architecture by attempting to follow the so-called Gothic revival. He set to work vigorously to change things, and started an atelier in which he had as pupils Mr. George B. Post and Charles Gambrill, Professor Ware and Henry Van Brunt. In 1870 H. H. Richardson returned from Paris, and in his work he attracted the attention of the public to the difference between the work of an architect and that of engineers and builders, and his influence extended all over the country.

Hunt, who found his taste for Classic work opposed by the wave of Gothic and "Picturesque" popularity, had meantime compromised with the public by taking into association with himself Henry O. Avery, and together they produced the design for the William K. Vanderbilt house. Marquand house, and others in the French Transitional styles of Francis I. and Louis XII. Henry P. Kirby, of New York, produced some fine imaginative studies in this style, which he published in his book of "Compositions." A number of strong men were won over to the style of the early French Renaissance, including Ellis, who produced some interesting work in St. Louis, among other things the City Hall; Bruce Price, of New York, who designed the Château Frontenac, an hotel for the Canadian Pacific Railway at Quebec; and Clarence Luce, of New York; Louis Hickman, of Philadelphia; Julius Schweinfurth and George Newton, of Boston, made studies of conspicuous merit, nearly all of which were produced between the years 1888 and 1892. In 1889 several works by Messrs. Carrère & Hastings were published, which had been built at St. Augustine, Florida, in the style of the Spanish Renaissance, but highly original and beautifully adapted to American needs, composed on lines of pure design and ornamented with paintings, mosaics, and decorative sculpture. Messrs. McKim, Meade & White produced several works in the Italian Renaissance style—the Villard houses and the Century Club; the Madison Square Garden, with the tower similar to the Giralda of Seville, and the New York *Herald* Building, by Stanford White. The publication of the early studies by Mr. McKim for the Boston Public Library, which clearly showed that it owed its inspiration to the Library of St. Geneviève, in Paris, had a very beneficent influence, and for several years was regarded by architects and the public generally as the finest example of architecture in the United States. Its extent and costliness indicated something of the demands for education of the citizens of Boston, and its conservative architecture is unquestionably only a reflection of the character of the representative people of that city.

The Columbian Exhibition, said Mr. Swales, afforded an opportunity, for the first time, of bringing together the combined artistic abilities of several of the then leading architects of the country. Again, the best work owed its inspiration to French designs. From the time of the Exhibition down to the present day the history of the development of American architecture disclosed a rapid march of progress. The Classic influence, re-established in the public favour by the Exhibition, had been maintained, and accepted in one or another of its manifestations throughout the country. Numerous architectural schools have been founded; and the old ones at the Cornell, the University of Illinois, and the Massachusetts Institute of Technology, improved their courses of instruction, modelled in principle upon that of the great school of Paris. The atelier system, first attempted by Richard Hunt, was successfully inaugurated about fifteen years ago (by Mr. E. L. Masqueray, since chief architect of the St. Louis Exposition, who was at the time Hunt's chief assistant) and has been fostered by the Society of Beaux-Arts Architects, which has made its principal objective the education of the younger men. The Architectural League of America—a society composed of societies—whose members are the various architectural clubs, which, in several of the large cities do auxiliary work to that of the Society of Beaux-Arts Architects, especially as regards the education of those office-trained men whose circumstances prevent them from taking a regular course in one of the universities. These have given birth to and rock the cradle of the architecture of the future.

In the third part of his paper Mr. Swales explained the schemes which were afoot for the future development of Washington on the lines of L'Enfant's plan. A Senate Commission had appointed an advisory committee (Messrs. Burnham, McKim, Olmstead and St. Gaudens), and they were instrumental in inducing both the Pennsylvania and the Baltimore and Ohio Railroad Companies to remove their tracks from the Mall so that the original scheme could be advanced. The whole improvement is to be made on a grandiose scale, and such is the admirable spirit of public enterprise now prevailing that it is likely to be an accomplished fact within a few years. Mr. Swales also attributed some of the success of the movement and the possibility of its ultimate completion to the unity of the different American architectural societies. He accounted for this hopeful condition of art in America, first, to the system of education which enabled Americans to know who their strong men were while they were still young—a system that was competitive and the results of the competitions made public. It was the French system—that of the Ecole des Beaux-Arts—where each student knew exactly the standing and record of every other student as well as his own in every subject. The entrance examinations were to the schools—not to the Institute. Before a student had spent much time or money he knew whether it was likely to be worth his while to do so. Secondly, to fellowship which arose out of friendly association with one another in the architectural clubs, the universities and the ateliers in Paris. To the influence upon a large personal following of young men by such strong leaders as Messrs. Charles McKim, John M. Carrère, George B. Post, Walter Cook, Cass Gilbert and E. L. Masqueray; and of the college professors, Wm. R. Ware, A. D. F. Hamlin, D. Despradelles, Warren Powers Laird, Frederick M. Mann, Emil Lorch, Paul Cret and others; but more particularly to the generous impulse of one of the present leaders, who had a great opportunity to show his mettle and proved equal to the occasion. This was the man who might have designed in his own offices all of the buildings at the Columbian Exposition, but chose rather to recommend to the Exhibition Company to give out five of the largest buildings to his ablest contemporaries in his own town of Chicago and five others to men practising in different parts of the country, whose loyalty to these co-workers was never found wanting, and whose integrity and ability—artistic, organising and executive—proved him to be the fittest to lead, though he con-

Digitized by Google

ceded himself that leadership to Richard Morris Hunt during his lifetime—Mr. Daniel Hudson Burnham, of Chicago, chairman of the Senate Commission, which recommended to the Senate that the plan of the great L'Enfant should be adhered to.

Mr. F. M. SIMPSON proposed a vote of thanks to the lecturer, and said Mr. Swales was peculiarly qualified to read such a paper, as he was one of the brilliant staff of designers who were responsible for the lay-out of the St. Louis Exposition and a pupil of the Ecole des Beaux-Arts. They had heard an admirable description of the work going on in America at the present time, and they all appreciated the excellence of the designs which had been put before them. The moral they could draw from the paper was the wonderful influence that the French education of the American artist had had upon their designs. The jump that had been made since the time when Hunt returned from Paris was marvellous. In the Americans they saw a nation pre-eminently practical dealing with vast commercial interests, grafting on to their own gigantic needs the traditions, training and the exact knowledge and delicate feeling for Classic beauty which they obtained from France. He wished also to draw attention to the point in the paper where the authorities in charge of the improvements at Washington found that the tremendous railway stations of the Pennsylvania and Baltimore and Ohio Companies prevented them realising their scheme, they sent their architects to the railway companies asking them to help, and the latter most generously did so. He wondered whether London authorities would be as successful in a request to remove Charing Cross railway station and the bridge across Ludgate Hill.

Mr. JOHN SLATER seconded the motion.

The PRESIDENT said it was delightful to think of a city in which the people as well as the architects were willing to make sacrifices for beauty.

The vote of thanks was passed by acclamation.

THE BUDDHIST AND HINDU ARCHITECTURE OF INDIA.*

(Concluded from last week.)

THE whole surface of India is covered with Hindu temples, the vast majority quite modern or comparatively modern. The number of ancient shrines is small, chiefly in consequence of the destructive religious fury of the Mohammedans, who invaded India from 1000 A.D. onwards. The oldest specimens date from about 600 A.D., and the best examples are to be found between that date and 1300 A.D. In surveying these ancient monuments we can clearly distinguish two styles, each of which shows a definite type from the beginning. The geographical distribution of these two types is, to begin with, rather interesting. For the Southern or Dravidian style of Hindu architecture is found only within the tropics, or south of the the twenty-third degree of northern latitude. The Northern or Indo-Aryan style, on the other hand, is found only north of the tropic of Cancer, excepting only the eastern and western extremities of its territory, which come down to the twentieth degree. A historical study of these two, moreover, shows that the Hindu temples of both styles are developments of Buddhist prototypes. But the remarkable thing is that they are respectively the descendants of two entirely distinct classes of Buddhist building; for it can be shown that the Dravidian Hindu temple has been evolved from the Buddhist monastery, while the Indo-Aryan Hindu temple has been developed from one of the other two classes of Buddhist building.

The earliest representative of the Dravidian temple is at Mahabalipur, thirty five miles south of Madras. It is a monolith, being hewn out of a single block of granite, and dates from about 600 A.D. It is clearly Brahmanic in origin, as is shown by the sculpture as well as the inscriptions. But it is evidently also a model of a Buddhist monastery of four storeys. The plan is square, the pyramidal tower representing the upper storeys containing the cells of the monks. The design of the regular structural Dravidian temple is a square base ornamented externally with pilasters, and containing the cell in which the image is kept. Over the shrine rises the sikhara, a pyramidal tower, which is always divided into storeys. This division never disappears in Dravidian temples. The tower is crowned with a small dome, either circular or polygonal in shape.

* Abstract of a paper read before the Society of Arts by Professor A. Anthony Macdonell, M.A., Ph.D., F.B.A.

An early example of the Dravidian style of Hindu temple on a grand scale is at Ellora, which dates from the seventh century A.D. This also is a monolith, but on an enormous scale. It is, really, one of the wonders of the world, for it is a temple carved elaborately inside and outside, out of a single huge rock left standing after a wide passage had been cut away in the hill side around it. Out of this living rock were cut shrines, porches, columns, halls, steps, galleries, roofs, and the most detailed sculptures 1,300 years ago. Much of the sculpture is still as clear as when it was first carved. It would take a large volume to illustrate fully the details of this marvellous structure. It is the culmination of the art of rock-cutting in India.

In front of the Dravidian temple a porch, or even two porches, may be added, but these are not an essential feature of the building. The later Dravidian temples from about 1000 A.D. stand in a large court surrounded by an enclosing wall. A special feature here is the great gateway, erected in front of the shrine in the wall which encloses the court around the temple. It has a storeyed tower, resembling that of the shrine itself. But it is oblong, not square, in shape, being twice as wide as it is deep. The best specimen of the structural temple in the style is that at Tanjore, which was erected in 1025 A.D. The body of this temple is of two storeys, about 80 feet high, while the pyramidal tower rises in eleven storeys to a total height of 190 feet.

Many of the famous later temples of Southern India are architecturally a good deal spoilt by two main defects. In the first place, successive independent additions obscure the design of the original shrine, producing a sense of bewilderment in the observer. The second defect is that the gateways in the walls of the successive courts, which have subsequently been added, increase in size and height as you proceed outwards, thus entirely obscuring the tower of the central shrine. Both defects are specially striking in the Srirangam temple, near Trichinopoly, which is the largest in India. Here there is a fifth court which was added, but left unfinished, in the middle of the eighteenth century. The shrine itself is quite insignificant, being distinguishable only by the gilding of its dome, while the gateways of every court are each larger and more decorative than the preceding.

About sixty miles from Gadag is situated a place which is virtually a vast open-air museum of Hindu monuments in the Dravidian style. This is Vijayanagar, the ruined capital of a Hindu kingdom, which was founded in 1118, and remained a bulwark against Mohammedan invasion for two centuries and a half. The city was at last captured in 1565, and has remained deserted ever since. The ruins of palaces and temples cover an area of several miles. The finest temple here is that of Vittoba Svami, erected soon after 1500 A.D. This, together with two other shrines, is surrounded by an enclosure with four Gopurams or great gateways. The finest part of the main shrine is the porch, which is notable for its elaborate composite pillars and columns with richly carved figures of conventionalised animals attached to them in front. Close to this temple is to be seen in the court the stone car of the god, 26 feet high, carved out of a single block of granite. The stone used in all the buildings at Vijayanagar is granite, and the enormous size of the slabs used is very remarkable. A walk of rather over a mile brings one to the great temple of Siva. This temple is in use, as there is a small village close to it. It has a great Gopuram at the north entrance. Taken in all its dimensions (being over 165 feet high) this gateway is, perhaps, the largest in India.

To each of the great temples of Southern India is attached a large tank for the religious ablutions of the worshippers. Sacred tanks not within the precincts of a temple are also frequent in Southern India. These are called Teppa kulam, or raft tanks, with a small shrine in the centre, to which at certain festivals the image of the god is taken across on a raft. One of the features of the Madura and other great South Indian temples is the colonnades which surround the tanks. Other South Indian temples have colonnades around their court. This is the case in the great Siva temple at Vellore, not far from Madras. It is one of the most remarkable shrines in South India. It has a Gopuram, seven-storeyed, and 100 feet high. The colonnade which runs round the enclosure is supported by nearly 100 carved pillars.

Here may be added a few words about the columns of the South Indian style. The early Dravidian temples had conventional lions and elephants of normal shape as supports of their pillars. These were gradually enlarged and affixed to the pillars, as at Madura; the animal forms being

Digitized by Google

conventionalised with riders. Human and other figures were then introduced as supporters.

One of the most sacred shrines of India is the great temple of Ramesvara, sacred to Rama, situated on an island close to the mainland, in the channel between South India and Ceylon. It has a magnificent Gopuram. Its most striking feature, however, is the wonderful corridors which adorn it. The south corridor is 700 feet in length, that is to say, it is the longest in the world excepting that in the Vatican.

A variety of the Dravidian style is that which has been called the Chalukyan by Fergusson, after the dynasty which ruled from about 400 A.D. onwards in the territory where this variety prevails. It embraces the northern and the north-western part of the region covered by the southern style of architecture. The peculiarities of this style are these. The ground plan is star-shaped, and the tower is stepped rather than storeyed, forming a square pyramid with breaks corresponding to the angles in the walls. The temples generally stand on a terrace from 10 feet to 15 feet wide, and 3 feet to 6 feet high, a feature which adds very greatly to their architectural effect. The best examples belong to the period between 1120 and 1270 A.D. The most perfectly preserved example is the temple of Somnathpur, about twenty miles from Mysore city. The buildings were erected without mortar, the joints being carefully fitted. The details of this style are very elaborate, most of the finer temples being overlaid with sculptural ornament, consisting of floral patterns intermixed with mythological figures. But the most attractive of all the Chalukyan shrines is the great temple of Siva at Halebid, delightfully situated on a terrace near the shores of a lake. It was left unfinished in the year 1270 A.D., the towers never having been added. It is one of the most remarkable monuments in India. One of the pavilions in front contains a huge image of the Bull of Siva. In the interior are some remarkable black stone pillars, which look as if they had been turned in a lathe. This temple is unmatched in the variety of its details and the exuberance of fancy shown in its ornamentation. There is, perhaps, no other temple in the world on the outside carving of which such a marvellous amount of labour has been spent. It will give some idea of the enormous amount of sculpture with which this temple is covered when it is mentioned that the lowest band of the frieze alone contains a procession of about 2,000 elephants, no two of which exactly resemble each other.

Now turn to the Indo-Aryan style of Hindu architecture. By great good fortune there are extant side by side two of the earliest examples of the Dravidian and Indo-Aryan styles near Badami, in the Chalukyan territory. They date from the end of the sixth century A.D., and already show fully developed the characteristic features which the two styles clearly retain down to the present day. Both have a square base containing the cell, but while the Dravidian temple has a pyramidal tower, always divided horizontally into storeys, the northern tower is a curvilinear spire, not divided into horizontal storeys, but, on the contrary, having a vertical band running up each face. While the Dravidian tower is surmounted by a small round or polygonal dome, the Indo-Aryan tower is surmounted by a circular fluted ornament, somewhat flattened at the top. The Indo-Aryan, like the Dravidian shrine, has a porch nearly always added in front of the entrance to the cell, but it was evidently not essential, not being an integral part of the edifice. The shrine itself consists of two parts. The lower part containing the cell is square. It rises from a moulded plinth and ends in a cornice. There are never any pillars or pilasters. Above this rises the spire, which is square in section, and the curve of which in the early specimens begins near the top. The central vertical band was carved, usually with a reticulated ornament composed of minute arches. The Mandapam, or porch, is added in front of the doorway of the cell, and is square, being of the same height as the top of the shrine where the spire begins. In the earliest specimens there were no pillars, and the roofs consisted of long sloping slabs. Later, columns were introduced in groups of four, and courses of masonry were made outside to correspond to the carved conical roof inside.

The earliest representatives of the Indo-Aryan style are found in the group of deserted Hindu temples at Bhuvanesvar in Orissa, about 250 miles south of Calcutta. The older and finer specimens begin from about 600 A.D., the series coming down to about 1100 A.D. They show this style in its greatest purity, and probably furnish better material for the history of this form of Hindu art than any other temples in India. To the ninth century belongs the celebrated Black Pagoda, a temple of the Sun, at Konarak, in Orissa, about twenty miles from Puri, and within sight of the sea. It represents the car of the Sun drawn by seven horses, with twelve gigantic, elaborately carved wheels of stone on each side.

The famous shrine of Jagannath, the lord of the world, a name of Vishnu, was erected about the year 1200 A.D. Within its enclosing wall, which is about 20 feet high, are crowded together something like 130 shrines. Puri is a great place of pilgrimage from all parts of India, but the great crowd of pilgrims assembles at the car festival in June and July. The great car, which is 45 feet high and 35 feet square, is then, with the image of the god placed on it, dragged from the temple to the garden house of the god, situated at a distance of about a mile. In pulling the great car and two lesser cars along, a throng of more than 4,000 professionals are employed. After the festival, these wooden cars are broken up and the fragments distributed to the pilgrims. Thus when pilgrims eat the sacred food within the precincts of the temple, all caste distinctions disappear. The highest Brahman would then take food from the hands of a man of the very lowest caste: a thing otherwise impossible in India.

The origin of the Indo-Aryan spire has always been a puzzle to Eastern archæologists. Thus Fergusson says:—"Neither the pyramid nor the tumulus affords any suggestion as to the origin of the form, nor the tower, either square or circular; nor does any form of civil or domestic architecture. It does not seem to be derived from any of these." Here, then, we are faced with a fascinating problem. The Indo-Aryan Hindu spire appears fully developed in its earliest occurrence about 600 A.D., beside the Dravidian Hindu pyramidal tower. It has clearly no connection with that tower. But it can still less be a development of the Buddhist Chaitya or church, with its waggon-headed roof and semicircular apse at the end, which shows no suggestion of anything like a spire about it. Where then are we to look for its source? I believe the answer can be given with certainty, or at least a high degree of probability. The Buddhist Stupa in the cave temples gradually developed from a plain solid dome into an elongated hollow cell containing an image of Buddha. The transition from the solid to the hollow Stupa is further illustrated by model Stupas at Bodh Gaya. Then we find near Badami an old structural Hindu temple of Vishnu dating from the seventh century A.D., containing a similar hollow cell for the image, the back of the cell being still semicircular. In that neighbourhood we find another old Hindu temple, the same in other respects, the only difference being that the cell has become square. Now, there are to be found in Northern India a number of simple Indo-Aryan shrines erected without porches. These evidently bear a strong resemblance to the transformed hollow Stupa. In place of the original round drum is the square base, as more suitable in form for a cell. Above this rises the spire in place of the elongated dome, and still retaining the vertical curve of the latter, but modifying its circular shape by carrying the corners of the square base to the top. Thus the horizontal section of the spire becomes square also.

Finally comes the explanation of the ornament at the top of the spire. We may dismiss the theory that the fluting is an imitation of a certain small Indian fruit. In the earliest examples of Indo-Aryan temples there is a neck between the top of the spire and the ornament. One of the rock-cut Stupas at Ellora indicates that the neck represents the lowest part of the tee, and the ornament above represents the upper part, the fluting being a rounded modification of the vertical divisions in the tee. The curved flattened top probably represents a single umbrella. In one of the rock-cut Stupas at Ajanta, the three umbrellas carved in stone above the tee are themselves fluted. These in turn are surmounted by the vase-shaped finial which regularly appears at the top of the Indo-Aryan spire.

Thus we arrive at the remarkable conclusion that, while the Southern Hindu temple has been evolved from the Buddhist monastery, not only Buddhist temple architecture outside India, but also Hindu temple architecture throughout Northern India, is a development of the Buddhist Stupa. In the Northern Hindu temple the dome of the Stupa was elongated, while the umbrella ornament became attenuated. Outside India the dome was gradually attenuated till it finally disappeared, while the umbrella ornament grew to such an extent that it finally became a tower 200 feet in height. With the red thread of historical study to guide us, we are thus enabled to understand clearly what otherwise presents itself as an inexplicable mass of disconnected phenomena in the domain of early Indian architecture.

NOTES AND COMMENTS.

THE perfect handbook on building construction has not yet been produced, but there are some that approach more nearly to the ideal than Mr. ALLEN'S "Practical Building Construction." The fact that the fifth edition * is now before us is evidence that this book has won popularity, and at the price of three half-crowns is considered good value for the money. But it might be made better. We think it is not possible to produce at the price a book adequately treating of building construction and also including as much knowledge of materials, sanitation and history of architecture as is necessary for those students for whom the volume is intended. These subjects would be better omitted rather than insufficiently treated. That done there would be space for fuller treatment of matters more properly within the domain of construction. Hollow walls need further elucidation, particularly with regard to drainage, ventilation, and the finish at the base of the wall of the hollow space. The reason why bituminous internal vertical damp-courses sometimes fail should be explained, with the precautions necessary to avoid failure. Sections of rolled joists should always be properly drawn, not as on p. 119. Fig. 404 should also be correctly drawn. Fig. 457 shows a device which, it should be explained, is only sometimes permissible, and even then has its drawbacks. The details of Portland cement (unless omitted altogether) should be made to agree with the British standard specification. Obsolete forms of fire-resisting (not fire-proof) floors should be ignored, and more of the good modern ones, now omitted, put in their place. The diagrams of both flying and raking shores should be corrected, for as now shown they are impossible. It is dangerous to tell a young student that "the collar beam acts as a tie and prevents outward thrust." He should receive an explanation of the conditions under which collar beam roofs can be safely used, or he will find later by sad experience that they cannot always be so. Mistakes in spelling should be rectified, as, for example, "lear" board is a phonetic rendering of our modern corruption of the old name "layer board," which did express the function of the item.

THE oxyhydrogen blowpipe is a wonderful and powerful tool, but the Americans have found one still more remarkable by substituting acetylene for hydrogen, obtaining a much higher temperature than the 4,000° Fahr. of the older implement, and rendering easily possible the autogenous welding of cast iron, wrought iron, steel, brass, copper, and even aluminium. There is no need, therefore, to discard a kitchen boiler because it is cracked. The crack can be mended. By means of the oxy-acetylene blowpipe metals can be cut easily and truly, with smooth sides to the severed portions, and without perceptible injury by oxidation to the adjacent metal. A detailed account of this new tool is given in the *Scientific American*.

THE British Fire Prevention Committee has just issued a "red book" giving an account of tests with two steel rolling shutter doors known as the "Wilson" rolling shutter door, made and supplied by the Wilson Manufacturing Co., and fixed by Messrs. MOUNTAIN & GIBSON, Ltd. The test was very successful the classification of "Full Protection (Class B)" being obtained. The standard required for this classification is very high, four hours' exposure to a temperature gradually increasing to 1,800° Fahr., with subsequent applications of water for five minutes, being the principal conditions of the test.

A SUGGESTION for a British decimal system of measurement is made in *Indian Engineering*. The proposition is that our present land-surveying "link," or 7.92 inches, shall form the starting-point, and 5 links be our meter, then 20 meters equals 1 chain, 200 equals 1 furlong, 1,600 equals 1 mile. It follows that 2½ square meters equals 1 perch, 100 square meters equals 1 rood, 4,000 square meters equals 1 acre. The suggestion is ingenious, but the confusion between our meter and the widely adopted French system would be worse than ever. If we should in the future adopt a metrical system, it must be the French one, for the chief value of a change from our present system would be the greater facility it would give for international commerce and exchange.

ILLUSTRATIONS.

THE CHARTERED BANK OF INDIA, AUSTRALIA AND CHINA, CALCUTTA—INTERIOR.

THIS building has been erected in Calcutta for the Chartered Bank of India, the contractors being Messrs. MARTIN & Co., engineers and contractors, and the architect Mr. EDWARD THORNTON, F.R.I.B.A., both of Calcutta. The building is situated in Clive Street, in the centre of the business quarter of Calcutta, and is one of which the city may be proud. In fact, it may truly be said that Calcutta is really becoming a city of palaces. Mr. THORNTON'S work is now very well known in India, as he has designed not only several of the largest business premises in Calcutta (including Royal Insurance building and MARTIN & Co.'s new offices), but also several palaces for rulers of Native States.

ST. MICHAEL AND ALL ANGELS CHURCH, BECKTON, LONDON, E.—EAST ELEVATION—THE CHOIR.

THIS church has been erected to serve that portion of East Ham wherein is situate the Gas Light and Coke Co.'s works, &c. The architect has had to contend against a water-logged site, resulting in having to build on piers and arches carried down some 18 to 20 feet below the ground level. This necessitated a lower superstructure than is usual, in consequence of which the architect chose the Devon type, with barrel vaulted roof. The work was carried out for a sum of 10*l.* per sitting, inclusive of architect's fees, and has cost so far as built some 4,300*l.* The reredos and stalls are temporary, the former coming from the Mission Church adjoining, the latter being to special design. The work was carried out by Messrs. JOHN BARKER & Co., the heating by Messrs. JEFFREYS & Co., the lighting by the Gas Light and Coke Co., and the architect is Mr. A. H. RYAN-TENISON, F.R.I.B.A., of 21 Great Peter Street, Westminster, S.W.

CAMDEN CHURCH, PECKHAM—THE CHOIR, AS RESTORED AFTER FIRE.

THIS church was partially destroyed by fire in 1907. The restoration was entrusted to Mr. A. H. RYAN-TENISON, F.R.I.B.A., of 21 Great Peter Street, Westminster, S.W.

The instructions given him were to reinstate in every case, so far as possible, the original work designed by the late Sir GEORGE GILBERT SCOTT, R.A., and Mr. JOHN RUSKIN. This has been done to the satisfaction of all. The architect has provided new choir stalls in oak of late design, a new mosaic flooring, a new organ chamber, and other works, comprising a partial rebuilding of the west façade, nave walling, and an entirely new roof of open timber construction for the nave. The church is now lit by electricity, with a gas installation for cases of emergency. The interior has been colour decorated.

Mr. VOGEL GOAD, of Camberwell, was the contractor. The stalls and other works were executed by Messrs. WAKE & DEAN at their Yatton works. The stained-glass work in renewing the window destroyed is the work of Mr. PERCY E. DEMAIN HAMMOND. The works in renewing the original organ are by Messrs. GREY & DAVISON, and the electric lighting by Messrs. WELLS, RAYNER & Co. The total cost amounted to nearly 6,000*l.*

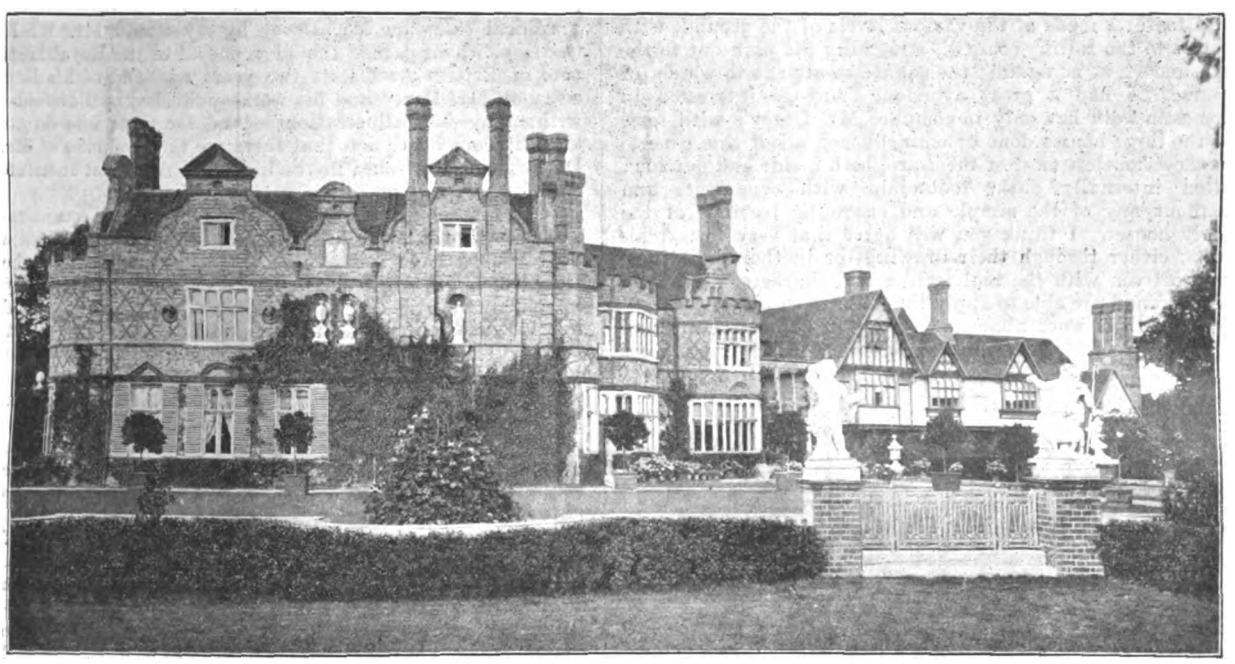
GEORGE DEVEY AND HIS WORK.*

(Concluded from last week.)



IT is interesting to note, now that garden craft has become such an important adjunct to the complete design for a country house, that Mr. Devey was certainly one of the first in our time to take any practical part in its development. The immediate approaches and surroundings, the entrance courtyard, the enclosing walls and archways, the terraces, the disposition of steps and the arrangement of gardens connected with every well-appointed house, he always held came properly within the province and should be the work of every competent architect. And he attached great importance to the comprehensive treatment of all this as a vital and necessary part of the whole design. The sympathetic consideration of these things was always a joy to him, and he was singularly happy in the variety of charming features which he invariably produced, all admirably adapted to the different needs and local circumstances. An excellent example may be found in Coombe Warren, where the best characteristics are all brought out, making that attractive collection of accessories mostly to be met with in old houses and their surroundings. A house standing alone, with the winds of heaven sweeping round it and without the friendly shelter of walls, was to him a horror. He loved a brick or stone wall attached to every house, going round the entrance court with gateways and doors according to requirements. This you will find with most of his houses when he had his own way, together with that feeling of welcome mystery where, as you approach, the wall prevents your seeing everything at once, leaving play for romance to picture Elysian fields on the other side.

The commissions chiefly consisted in country houses, although there were a number of new schools and churches he repaired. At the busiest time there were about ten men in the office, one modeller in constant work and six clerks of works. For some years George Myers, the builder, carried out the largest works, and in this there was the great advantage of dealing with one set of men who knew your ways. (He was the same Myers who in former years had done so much of the great Pugin's work.) But, satisfactory as this was, Mr. Devey hated the contract system, with all the endless bickering and compromises so often involved, and with the difficulty there always was in carrying out a new idea or a second thought. So, having had experience of how successfully some things had been done by estate works (I think it was at Lord Vernon's, Sudbury Hall), arrangements were made and a system adopted whereby the client built on his own account. This worked well for years and was carried out concurrently with contract works, in other cases and in the usual way, where the client wished it. Of course, this new departure entailed more work, for which an additional 2 per cent. was charged. In large and important works it was a great relief not to feel bound within the limits of a contract, although in all cases a careful approximate estimate was given, but the chief advantage was to the client, where the work was better done and at less cost than by contract. Of course, some builders may question this; everything, however, depends upon the efficiency of the system and the superintendence. Given this and there can be no doubt as to the time and cost being less and the quality of the work better. Remember in this case that the architect is in no sense the builder. He arranges the system which the client's foreman carries out. The workmen are engaged by the foreman, who also orders all materials—under supervision. A monthly statement was always rendered, which put the client in possession of all information and removed the possibility of misunderstanding.

Such a system required the confidence of the employer, and that Mr. Devey always commanded. It is needless to say that Mr. Devey personally had little to do with the practical work involved in all this, although he would do anything that he considered the duty to his client required, but he was essentially an artist.

Although Mr. Devey was not a well-known man, it is interesting to remember what a number of distinguished people he had as clients. Here are some of them:—Her Majesty the late Queen Victoria, the late Duke and Duchess of Sutherland, the late and the present Duke of Argyll, Lords Granville, Spencer, Lytton, Kenmare, Lucan, Revelstoke, De L'Isle, Dunraven, Strathnairn, Northbourne, Vernon, Cranbourne, Stratford, Tankerville, Cranbrook, Carlingford, Rothschild, the Countess of Waldegrave and a number of others.

The late Earl Granville, a most genial and charming man, who, as ambassador, had been to all the great courts of Europe, was a very good friend and client. He would call at the office and walk off arm-in-arm with Mr. Devey, consulting him frequently on various matters of taste. He had great faith in Mr. Devey's judgment and advice. When the earl was Foreign Minister, Devey would often dine with him at Carlton House Terrace (where he had made considerable alterations and improvements), and afterward attend the receptions at the Foreign Office. It was at one of these banquets, sitting between Sir William Harcourt and the Bishop of Oxford, that Sir William began talking to Devey of a wonderful house being built for a friend of his in Oxfordshire, where the architect, an ingenious and clever man, by using old stonework and tiles, had managed to make a most charming and old-looking mansion. Sir William was afterwards very much amused to find that he had been talking to the architect.

COOMBE WARREN.

* A paper by Mr. James Williams, read at the last meeting of the Architectural Association.

Digitized by Google

No account of Mr. Devey's work would be complete without some notice of the excellent staff of men who were in the office, many now occupying important positions in life, especially the invaluable services rendered for many years by Mr. Arthur Castings, an accomplished architect, who, but for a retiring nature, might have been better known and whose ability may well rank with that of the best living men. There was also the late Mr. Henry Smith, his surveyor; you all know what an important part a good surveyor plays in every office, and he was indeed a trusty friend and adviser for whom we all had a great regard.

In talking of the duties of an architect one is reminded of an answer given to an unreasonable complaint where a clerk of works was employed, and which at the time struck one as very much to the point—that you never expect a doctor to act as doctor and nurse. Mr. Devey rarely criticised the work of contemporary architects and never unkindly, but there was not much about this time that he was in sympathy with.

In the arrangement of a house, whether large or small, few appeared to realise, as he did, the requirements and conveniences of a comfortable home. Things are different now. The advice given by a client about servants' accommodation, that unless they were given some luxuries there was little chance of his living in common comfort, was hardly necessary in Mr. Devey's case. He was considerate for all alike. The plan was carefully thought out and specially adapted to the site chosen, advantage being taken and features made of the various levels of the ground, with gables to the falling country, stretching the plan out to the sun and view, as against the square treatment to which, of course, he had a great aversion. Anyone interested in domestic work has only to compare Mr. Devey's with some of the large houses done by eminent men about this time to see how hopeless most of them are, both inside and outside; often internally dark, redundant with ornament, and without any of the simple and charming features of the early houses. I think you will agree that very few architects, either through their drawings or in their buildings, impress you with the real feeling and character of the old masters and are able to apply this to modern requirements—making their work alive and strong in expression, full of life and vigour. Simplicity and honesty of construction are

its chief characteristics, and these Mr. Devey always aimed at. It almost seemed that everything he drew was full of this subtle spirit, and you will readily understand how depressing it sometimes was to see the painful contrast between the master's sketch and the actual working drawing.

He was very much against the use of iron construction when it could be avoided; and it was amusing to hear him discussing the thickness of web and flange with his surveyor, who always allowed a very ample margin, but Mr. Devey invariably added something, saying that we seemed precious afraid of the girder "going up." He prophesied a great day of reckoning, when, one by one, they would all collapse about our ears.

Mr. Devey held that it was the duty of the architect to carry out the wishes and ideas of his client—after submitting his own—and he would never try to force his ideas on anyone.

In making additions to a house he would generally carry them out in harmony with existing work, however simple that might be. He altogether objected to the display of new architectural patches of an entirely different character so often seen, and so much like the self-assertion of the superior person.

Few men have ever been gifted with such a wealth and variety of alternative good ideas and suggestions as he could produce, both for plans and elevations. This was a great accomplishment, but at times, as you may suppose, it was

an unwelcome cause of delay when working drawings were sorely needed on a building to keep things going.

Most of you are no doubt aware of the excellent biographical essay on Mr. Devey by my friend Mr. W. H. Godfrey, which gained the silver medal of the Royal Institute of British Architects two years ago, and of his later essay on Mr. Devey and his work—published by Batsford—with many good illustrations. And for those who do not know it I may mention that there are three volumes of Mr. Devey's small sketches in the library of the Royal Institute of British Architects.

One of the last things Mr. Devey had under consideration was that all who had worked in the office more than a year should have some share in the profits, and had he lived this would have been carried out. The last journey he made was to the Earl of Kenmare's, at Killarney, one of his largest works, and then on to Lord Dunraven's, at Adare, about some proposed additions, during which time he contracted a serious cold, resulting in pneumonia, from which he died at Hastings in 1886, in his sixty-seventh year.

It is now more than twenty years since Mr. Devey died, but anyone who knew him intimately could never forget the impression he made on them. No words can express his natural charm of manner and refinement. Quiet, modest, somewhat reserved at first, at times vivacious, alert, full of humour, of deep feeling and genuine sympathy, considerate, thoughtful, kind and generous, showing great indignation against all injustice and the warmest approval of everything noble and good. With large and expressive eyes he saw much more than most people. He was passionately fond of music, with a fine taste and appreciation for the best in everything, a man of the highest honour and of entirely unselfish disposition, of a reflective and independent mind, not accepting the ordinary and general view without being fully persuaded in his own mind, true to himself, maintaining high principles and noble sentiments, with modesty and the firmness of real conviction.

No one was ever in his company without being the better for it. He had the deepest reverence for and delight in all life, in the flowers and the trees, which he could draw with such feeling and delicacy; with all animal life, from the smallest insect, which it was never beneath him to protect, to his horses, always his friends. While to all about him, in whatever position, he was ever the true gentleman, and in every sense a worthy member of your noble profession.

Mr. ARTHUR KEEN, who proposed a vote of thanks to the author of the paper, said there was always such an intimate association between the work of an artist and his personal qualities, that anyone who made them known rendered a great service to those who were interested in the life work of the artist. The lecture they had heard would therefore be appreciated, and similar papers dealing with Mr. Butterfield and Mr. Burges would be welcomed and interesting. All the work done by Mr. Devey must be judged primarily by contemporary examples. Possibly some of the photographs of the buildings they had seen would seem to lack distinctive qualities, but they must remember that architecture then was at a very low ebb, and domestic work often very bad, although there was a certain amount of creditable church architecture. The quality therefore of Mr. Devey's work

Digitized by Google

must have been a revelation, and especially so when they remembered that Penshurst was undertaken in 1850, some twenty years before Mr. Norman Shaw began to influence the style of building. Mr. Devey's plans were remarkable as showing very fine feeling for the external effect, and though the leading characteristic of his work was its domesticity, yet there was extraordinary excellence in all the arrangement of it. He realised that a house should be a home, and the illustrations they had seen were evidence of how well he succeeded. They had not, however, been shown much of the garden work, which was justly praised for its greater freedom in the customary formal arrangement.

Mr. NEEDHAM WILSON seconded the vote of thanks, and said one of his first earliest architectural experiences was connected with a visit to some work of George Devey's, near Bolton, in Lancashire, and which he found full of charm. He would have liked to have heard what influence the work of George Devey had in the development of English domestic architecture, because, extensive and delightful as the work was, the retiring disposition of the man checked its educational influence among the other members of his profession. His designs were scarcely ever or never published in the architectural journals, and so it was in his lifetime almost wholly unknown except to a very few architects.

Mr. W. H. LEVERTON said the paper was a pleasant reminder of summer visits to delightful houses, and he suggested that excursions in the future might be again made to them.

Mr. ALAN POTTER wished to emphasise the interest of the non-architectural part of the paper. Such lectures were unfortunately rare in the Association, and he hoped papers of a similar character, dealing with modern architects and architecture, would become more frequent.

ROYAL SCOTTISH ACADEMY.

THE annual meeting of the Royal Scottish Academicians was held last week in the library of the Academy, Mound, Edinburgh, Sir James Guthrie (president) in the chair.

The resolution passed on March 3 to elect three painter Associates was confirmed.

The eighty-first annual report, which was submitted by the Council and adopted, stated that the year ending December 31, 1908, was the first in which the changed date of the Academy's business year has come fully into operation. There had been less immediate inconvenience than might have been expected from the change, and the Council hoped that it would ultimately conduce to the smoother working of the Academy's affairs. The year had been an arduous one in many ways, and both Academicians and Associates had been called on to render services implying much time and anxious thought in various directions other than the routine duties of membership. As it was thought advisable, in the interests of his health, that Sir James Guthrie should spend the spring months abroad, Mr. Blanc again acted as his deputy, with much acceptance to the various meetings over which he had to preside, till, towards the beginning of May, the Academy had the pleasure of welcoming their President home in restored health.

The eighty-second annual exhibition was opened to the public on Saturday, February 1, and closed on Saturday, May 30. Five hundred and thirty-nine works were shown, 421 of these being paintings in oil and water-colour, thirty-seven works in sculpture, forty-one architectural drawings (including photographs of buildings exhibited by their architects) and forty miniatures and works in black and white. Following a custom of recent years, several representative pictures by two members lately deceased—Thomas F. Graham and David Farquharson—were borrowed for exhibition. Till the beginning of May the attendance was well maintained, but during the closing weeks it was adversely affected by the opening of the National Exhibition at Saughton.

At the statutory general assembly held on February 12 Mr. A. K. Brown was elected to fill the vacancy in the list of Academicians caused by the transference of Mr. John Hutchison's name to the honorary retired list. At the same meeting Mr. P. Hume Brown, LL.D., Professor of Ancient History and Palæography in the University of Edinburgh, was appointed the Academy's Professor of Ancient Literature, in room of the late Professor David Masson. During the month of February Mr. George Henry, whose headquarters have for some years been in London, was, at his own request, placed on the non-resident list. At the statutory general assembly held on March 18 Mr. R. Duddingstone Herdman, Mr. George Smith (painters), and Mr. Harry S. Gamley (sculptor) were elected to the rank of Associate.

The curators of the library reported as follows:—"As the library continues to be used for the general purposes of the Academy from the beginning of the year till the end of the first week in June, it has been found impossible to revert to the arrangement of having it open for one evening of the week; but the books are available for consultation or loan on application to the secretary or assistant secretary. The books, drawings and prints are, generally speaking, in good order and catalogued up to date." It was intimated that a number of works had been added.

During the year the Academy's collection of works of art was augmented by the following additions:—"Bronze Venetian Door-knocker;" "Two Stone Axe-heads," found near Greenlaw, Berwickshire; "Land's End, Cornwall," by William Miller, H.R.S.A.; "Fast Castle," by Thomas B. Blacklock; "Plaster Bust of the late William Forrest, H.R.S.A.;" "A Grey Day," by A. K. Brown, R.S.A., diploma work; "Head of the Venus de Medicis," monochrome study by Thomas B. Blacklock. The thanks of the President and Council were recorded to the donors.

The report of the visitors to the life class was as follows:—"The session of 1907-8 commenced on November 18, 1907, and finished on June 30, 1908. There were 122 meetings of the class, viz. sixty-six evening and fifty-six morning meetings, and the aggregate attendance was 1,318. The visitors have gratification in reporting on its efficacy and usefulness, as shown in the work of the students during the past year in drawing and colour, while the President's monthly prize has had a beneficial effect in original composition. The number of students on the roll is twenty-two and the average attendance is eleven. The Council, after inspecting the drawings and paintings done by the students during the course of the year, had pleasure in expressing their agreement with the visitors concerning the efficiency and usefulness of the school generally, and also in regard to the various studies produced during the session. The Council awarded the prizes as follows:—The Carnegie Scholarship, Hugh A. Cameron; the Chalmers Bursary, J. Howard Lyon and William A. Cuthbertson—equal; the Chalmers-Jervise prize for the best drawing from the life, Hugh A. Cameron; Maclaine-Watters medal, William A. Cuthbertson; the Stuart prize, George H. Paulin; the Keith prize, D. M. Sutherland and J. Howard Lyon—equal.

The Council had much satisfaction in recording the appointment recently made to the office of King's Limnership for Scotland, and they had the more pleasure in congratulating Mr. Robert Gibb on the honour conferred on him and on the Academy as there seemed some danger of that ancient and honourable office falling into abeyance. The Council took the opportunity of thanking those public bodies and individuals who so successfully used their influence in this matter.

The year has seen considerable development in those changes, in which the Academy were so deeply interested, involved in the passing of the National Galleries (Scotland) Bill two years ago. In particular the New Edinburgh Art College was pushed on so rapidly that at the close of the year the larger part of it was ready for occupation, and the classes which had been carried on with some difficulty at the Royal Institution were shortly afterwards transferred to the new premises. At an assembly of Academicians held early in the year five members of the Academy—three Academicians and two Associates—were chosen to act on the board of management; during the summer a director was appointed, and a teaching staff, which included several members of the Academy, was organised. The Council, in noting this new departure in Scottish art training and the greater and much-needed facilities it provides for the application of art to our various crafts and industries, would hope that it might also prove a stimulus to those higher branches of the fine arts in which the Academy were more directly interested.

The Council felt that some reference was due to the great art collections brought together during the summer and autumn months in Edinburgh and London respectively. The Edinburgh collection formed part of the Scottish National Exhibition, the leading intention of which was to show the progress and development of Scotland during the two centuries which had elapsed since the union of Parliaments in 1707. This idea was eagerly taken up by the committee in charge of the fine art section, and in no part was it so steadfastly kept in view or so thoroughly carried out

Digitized by Google

in any other section. Scottish art during that long period was admirably represented in the galleries at Saughton. To this result the Academy contributed materially, both by loans of works and through the labours of many of its members associated with the committees of collection and arrangement. It was matter of satisfaction to know that the collection was fully appreciated by the crowds who thronged the galleries from May till October. With the Franco-British collection the Academy was less intimately concerned, but the Council might draw attention to the initiative taken in the formation of a committee, on which several Scottish art societies were represented, the purpose of which was to obtain fair treatment for Scottish art in such exhibitions. And though the effort was not attended with direct success, the Council believed that the action of the committee had much to do with the more considerate treatment ultimately conceded in regard to the composition of the committee of arrangement; nor were they without hope that it might have furnished a basis for a still fuller recognition of the claims of Scottish art in future international collections. The Council also desired in this connection to express their sense of the excellent services rendered by Mr. Robert Noble as the representative from Scotland on the committee.

The Council regretted having to record the death of an Associate member, Mr. Archibald D. Reid.

It was interesting to record that during the year there occurred the hundred and fiftieth anniversary of the birth of Alexander Nasmyth, H.R.S.A., and the hundredth anniversary of that of his son, James Nasmyth. The former, who has been called "The Father of Scottish Landscape-painting," was born on September 9, 1758; the latter, the inventor of the steam hammer, on August 19, 1808. These names, so well known in connection with Scottish art and science, were now indelibly associated with the Academy through the munificent bequest made some years ago by the son in memory of his father, under the name of "The Alexander Nasmyth Fund."

The office-bearers were elected and the Council declared for the ensuing year as follows:—Council, Sir James Guthrie (president), Messrs. P. W. Adam, G. Ogilvy Reid, J. Campbell Noble, A. K. Brown, J. Lawton Wingate, J. H. Lorimer; W. D. M'Kay, secretary; Hippolyte J. Blanc, treasurer; G. Ogilvy Reid, G. Washington Browne, auditors; P. W. Adam, G. Ogilvy Reid, curators of library; J. Campbell Noble, E. A. Walton, Robert M'Gregor, Edwin Alexander, visitors of the Life School.

ASYLUM CONSTRUCTION.

AT a meeting of the Architectural Section of the Royal Philosophical Society of Glasgow held last week in the Society's rooms, Mr. Alexander Cullen presiding, Dr. Hamilton C. Marr, Woodilee Asylum, read a paper on "Asylum Construction." Dr. Marr said that St. Vincent de Paul in the seventeenth century was the first to proclaim "that the darkened mind was as much the visitation of God as the darkened vision; that Christianity demanded of the humane and virtuous and powerful to protect and the skilful to relieve the one as well as the other." Many years passed before this teaching was put into practice. In 1792 Pinel, in France, and three years later Tuke, of York, introduced what was known as the humane treatment of the insane. In practice the old association of insanity and demoniac possession was difficult to be got rid of. Thus in 1819, in connection with the lunatic asylum formerly in Parliamentary Road, the rotating motion by means of whirling chairs had been tried in a great number of cases and in some of these with wonderfully good results. Asylums originally consisted of cells, in which lunatics were bound down by chains and locked up. Shameful conditions of treatment of the insane in workhouses resulted in the Lunacy Laws of 1857 and the establishment of boards of lunacy and grants in aid of pauper lunacy. From one extreme it was only human to pass to the other, and many of their palatial asylums were the results of this rebound. Woodilee Asylum (opened in 1875, and then the Barony Parochial Asylum) was the first asylum to be built with sitting-rooms or day-rooms for the use of patients, open grounds instead of airing courts, and a maximum of freedom allowed by what was known as the "open-door system." The evolution of asylums all the world over had proceeded since 1875 towards the conception that as insanity was a bodily disease, the buildings for the insane should primarily be of a hospital nature. This was illustrated in modern Continental asylums in France, Germany, Holland, and Great Britain. When the details of asylums in these countries were considered the majority were found to be built on what was known as the block and corridor system, with, as at Gartloch and other asylums, a detached hospital, or with the hospital attached as at Woodilee. Chiefly through the writings and influence of the late Sir John Sibbald, His Majesty's Commissioner in Lunacy for Scotland, two asylums of the village type had been built in Scotland—Kingseat, Aberdeen, and Bangour, Edinburgh. These village asylums had their prototypes in Germany, and at Alt Scherbitz and Uchtspringe in Saxony. It was contended that the village asylum conduced to the greater welfare of individual patients by segregating them into small groups; that it was as economical in construction as the block and corridor type (this had actually been proved in the case of the Aberdeen, Kingseat, asylum, costing 230*l.* per bed); and that the village asylum could also be efficiently and economically administrated. Six years' experience of the Reception House at Woodilee showed that all insane patients could be treated in buildings of an ordinary hospital type, devoid of means for putting into use any system of restraint or deprivation of freedom by seclusion in single or padded rooms. The ideal mental hospital should consist of two portions—(1) a hospital section, (2) a colony. The hospital section would be divided into three parts—(*a*) a hospital, into which newly admitted patients and those requiring medical treatment on account of their bodily and mental condition would be placed; (*b*) villas grouped round a central kitchen and laundry for women requiring continuous medical supervision; (*c*) villas grouped round workshops for men requiring continuous medical supervision. The colony would consist of villas placed round farms for patients who did not require continuous medical supervision, but who required to be under sufficient observation in order to fit them, should they not recover, to be boarded out with strangers in the country. Such an asylum built in the country, accessible to the friends of patients at all hours, and with a sufficient allowance of ground for the employment and treatment of patients, should not exceed in cost 200*l.* per bed.

THE SOCIETY OF ARCHITECTS.*

THE object of this paper is the elucidation of some facts, which are not so widely known as they might be, concerning the changes which the last quarter of a century has effected in the importation and use of building timber.

The question is, What forms of timber can the architect specify for use in a given building which will on the one hand give his client the best value for his money, and will on the other permit the contractor and timber merchant to supply what is wanted without undue inconvenience?

It is incumbent upon all merchants and manufacturers to bring before the profession the fullest information as to changes in origin, form and manufacture. This is particularly true in the case of timber. Many of the ports which once sent us large quantities of the fir, pine or deal so largely used in building construction, both for joiners' and carpenters' work, have ceased to exist as sources of supply, and conversely other ports, till recently unknown, are now exporting to England some of the best and most suitable shipments.

It may be urged that the architect need not interest himself in areas of origin, ports of shipment or brands, it being his duty to see that good sound timber is supplied, irrespective of any other consideration. This might hold good if the standard of quality were always the same, and if builders and contractors were philanthropists eager only to please their clients and to achieve the highest possible level of artistic excellence in their work.

It has been the custom of the profession to lay down in its specifications certain definitions of what it requires in the way of timber for constructional and decorative work. The timber merchant and contractor are entirely within their rights in asking that these definitions shall be clear and definite, and as far as possible in accordance with the reasonable convenience of the trade. So far from deprecating any close and detailed limitations in the timber clauses, the sensible contractor asks for them. Nothing would please him better than to know that the terms used in describing the wood are meant and will be strictly enforced. Estimators now frequently complain that the formulæ tell them little or nothing. If they read them literally, they would never secure a contract under open

* Abstract of a paper entitled "The Specification and Inspection of Timber," by Mr. J. Davies, of *The Timber News*.

Digitized by Google

competition. They have to consider the class of erection in question and the idiosyncrasies and prejudices of the architect, so far as they are known to exist, plus the possibility of trouble from clerk of works.

So far from securing the desired level of quality, the clauses in question frequently open the door to the substitution of inferior materials. If the contractor demonstrates the inability of the timber merchants to supply satisfactory material of the exact description specified and obtains permission to supply something equal thereto, a great deal is at once left to his own discretion.

Many of the well-known builders and contractors may be associated with a certain set standard so far as their purchases are concerned. It varies with every firm, the experience of no two establishments being exactly alike. There are many who permanently exhibit an intense anxiety to carry out their woodwork in a manner creditable to themselves and just to the architects for whom they work. Even these are sometimes involved in serious difficulties through varying interpretations of timber specifications, and grave injustice has been inflicted upon them by the inability of architects to realise the difficulties of the situation. On the other hand, there are a few who prefer the existing state of things, and see in it opportunities for using indifferent wood under the excuse that what was specified is unobtainable and that "this is just as good."

Of course there are countless instances in which the good faith of the builders and the sound common-sense of the architect (best exhibited, when he has a conscientious firm working for him, in leaving as much to them as he can) have surmounted all difficulties without friction.

The wide differences between sundry clauses taken from recently issued bills of quantities will show clearly that all cannot be right and some must be wrong.

The first reads thus:—"The joiners' work to be executed with the best yellow Christiania or best red Petersburg deal"; and the second as follows:—"The joiners' work to be the best Christiania or equal quality deals."

These clauses are issued by eminent architects in active practice, associated with good work.

Christiania has not sent out, directly or indirectly, a good piece of joiners' timber for the last twenty years. The smaller wood that we receive from that place, in the form of planed boards, floorings and matchings, is of the class used in the most ordinary kind of speculating building.

One of these clauses permits the use of Petersburg stuff. This is more reasonable, but is open to the objection that it rules out by implication other ports which now send better and milder wood. Petersburg wood has shared the deterioration which has characterised the whole of our imports, and even the finest parcels show a considerable proportion of centres, knots and sap.

Another firm specifies the best Gefle yellow deal for joinery. This is nearer the mark, but similarly rules out other equally good Swedish shipments and the even more useful material which comes from the White Sea, except by the indulgence of the architect.

The next gives Onega, Petersburg or Archangel, leaving no room for even the best of the Swedish stuff.

Altogether it is clear that the information upon which these clauses have been based is very fragmentary and is greatly in need of revision. The same applies to the phrases governing the carcassing or carpentry. One says:—"The timber for carpenters' work to be the best Memel, Danzig or Riga fir, and no American, Swedish or Scotch fir is to be used in any part of the building."

Memel has ceased to send us fir. Riga still sends us fir, but of a spongy texture and poor quality. Danzig still sends fir in diminished quantities, of smaller sizes and lower quality than in the past. American red pine, which when obtainable is considered equal to any European stuff, is barred. Swedish fir is excluded. This rules out the firm, tough and elastic wood which comes in abundance from the best Swedish ports and which is largely used for high-class timbering. What is meant by the exclusion of Scotch fir is not clear. If the writer used the term commercially, indicating place or origin, it is unnecessary, as the quantity of Scotch fir or pine used in England or Scotland is negligible and would not enter into a builder's calculations. If he used the word botanically, to cover a species, he stultifies himself, as the Danzig fir, which he admits, and the Scotch fir, which he bars, are one and the same thing. No mention is made of Petersburg wood, which includes some very strong carcassing stuff.

Summarising the carcassing clauses, none of them specify the wood mostly used for constructional work where dimensions that are over 12 inches by 4 inches are required, viz. pitch pine, or in some cases Oregon or British Columbian pine. Most of our schools and municipal buildings are timbered in pitch pine or Oregon pine so far as the bigger sizes go, and in Russian or Swedish deals and battens where the smaller dimensions are concerned. Yet these items are not specified. Here we have a complete divorce between precept and practice, fraught with possibilities of endless disputes between the profession and the contractors.

It must be admitted that the task of compiling clauses which will govern the use of timber with fairness to all parties is not an easy one.

First, it may be appropriate to make a rapid survey of the important features of the timber trade to-day, with special reference to the soft woods, which form by far the largest proportion of imports. It will be necessary to examine the nomenclature of the staple building-wood in some detail, the terms which are variously applied to it being very puzzling to the uninitiated.

Although we speak of Memel or Danzig fir, the tree which yields it is a pine, botanically known as Pinus Sylvestris, a coniferous, needle-leaved tree growing very widely in Russia, Germany, Sweden and Norway and in some parts of Scotland and the North of England.

Whether in the form of squared-hewn logs from Danzig, or planks, deals and boards from Russia, Sweden and Norway, the wood is essentially the same, variations in its texture and quality being brought about by differences of climate and soil. That is why it is so difficult to draw distinctions between the shipments from various ports, any one shipment containing both fine, slowly grown and clean wood from the highlands, and coarse, wide-ringed and spongy stuff from the lower and moister ground. A joiner may get hold of a nice clean mild-working deal of a particular brand and swear by it ever after, giving precedence to a shipment the average quality of which may be very ordinary. Or he may come across a piece which is harsh and inclined to warp, or so resinous as to make it impossible for him to get a smooth surface upon it. He is then likely to condemn that mark for good, although its average quality may be very high. Possibly this is one reason why the men who actually work the wood differ so widely in their opinions about it and make such unreliable guides upon the subject.

It is known to the shippers as red and is so called in the Midlands and North; but most merchants and consumers in the South know it as yellow. It is thus variously called redwood, red deal, yellow deal, Baltic, Memel or Danzig fir, and has even two more names, Northern pine and Scotch fir, although these two are fortunately not often met with in the South.

It may be noticed here that the word "deal" is also used to denote a size, as 9 by 3, and in this connection has no relation to the name of the wood itself.

It is the wood about which nearly all the disputes occur, and is the one which is usually specified for most forms of building construction.

From thirty to fifty years ago it mainly came from Memel and Danzig, Stettin and Riga, in the form of logs, both round and squared. These were converted into carcassing and joiners' stuff in England, and undoubtedly yielded a large proportion of the finest and most durable wood. But as time went on Russia and Sweden developed an export trade in what is, as already explained, botanically the same tree. It came in a more easily merchantable form, viz. sawn square-edged planks, deals, battens and boards. Naturally the saving effected in buying the converted sizes had an effect upon the trade in Danzig and Memel stuff, and the imports of the latter fell away, until now we get very little indeed.

Still, as it was then correct to specify the latter variety, the terms became very firmly embodied in architects' specifications and have been copied and recopied until to-day. The situation is complicated by this fact, that although Riga fir is no longer of desirable quality and Memel fir is a thing of the past, we still get these hewn-squared logs from Danzig, and if an architect absolutely insists upon it, they can be had, although only in limited quantities and of very ordinary quality. Consequently, the builder who meets the recopied clause in a specification is faced by the probability that the architect is only using a figure of speech, but also the possibility that he has some reason for using the words and actually wants Memel or Danzig fir.

The question arises, "Where large sizes are required for main structural work, what is the best alternative, seeing that we do not receive imported planks larger than 12 inches by 4 inches from Russia or Sweden?" The answer to this

Digitized by Google

is pitch pine, and some would include the Douglas fir or Oregon and British Columbian pine.

The quality of nearly all timber imported into England has steadily deteriorated during the last twenty years, the leading exception—viz. Kauri pine—being unfortunately a joinery and not a carpenters' wood.

No doubt there are thousands of mature and well-grown trees in the forests of Europe and America which would yield just as good timber as that which we used to receive. But the trouble is that they are, so far, inaccessible. When the cost of carriage becomes prohibitive the shipper falls back upon those forests which lie sufficiently near to the railways and rivers to permit of his getting the wood to the port of shipment at a certain price. These have already been worked and the finest trees removed. Natural regeneration and State regulated replanting together fail to keep pace with the world's demand. European countries which once dipped very little into the available Russian and Swedish supplies now compete with the United Kingdom as bidders for yellow and white deal. At this moment Italy is buying it very largely for the erection of temporary buildings in Sicily and the mainland in consequence of the recent disastrous earthquake. The standard of comfort in the poorer countries is rising, which means that the demand for wood per head per annum is increasing. Our own Colonies import Baltic stuff for house building, finding it cheaper to do that than use their own woods, which are either too hard to work for the purpose or too valuable as exports.

Afforestation will not help us in our own generation. Although yellow deal now grows in the United Kingdom, it does not exist in really merchantable quantities or dimensions. The Royal Commission which has recently reported upon afforestation is of opinion that it can be grown here in bulk, and that scientifically planted forests will eventually produce good, clean, usable timber. But we shall have to wait about ninety years before the trees will yield cut stuff sufficiently wide and long.

Meanwhile the destructive process is going on, and the cutting of young wood in Norway and Sweden for wood pulp is further retarding the work of replenishment. While anxious not to appear as an apologist for poor or shoddy work, we must take these facts into account in the specification and inspection of timber.

Importers appeal to agents and shippers in vain for deals and planks which shall be free from sap, shakes, large, loose and dead knots and other defects. Money will not buy them. Timber is not a manufactured article, which a sufficiently tempting price will bring forth in perfection. The picturesque shapes which make a well-wooded landscape so attractive spell defects in the wood from an architectural point of view. If you take a walk through Kew Gardens, or through such a well-preserved section of the Sussex Weald as the Duke of Norfolk's natural park at Arundel, you will see some noble trees, but surprisingly few which are sufficiently straight in the stem and free from branches to produce a 20-foot plank free from pith, sap and knots.

To sum up, the wood of to-day is admittedly imperfect, and the question arises, "What measure of imperfection, if any, is permissible in timber used for contract work?"

The answer to that question will determine the wording of timber specifications. What shall we say about sap? It is safe to say the area of a transverse section of a typical Pinus Sylvestris will show about two-thirds heart and one-third sap. That two-thirds heart is roughly circular in shape. Cut a parallelogram from it. You have about half the area of the original section in that parallelogram, with a centre or pith in it. Can we afford to lose half the tree? Of course, everything depends upon the class of work in hand, and for some exceptional contracts no doubt every particle of sap must be eliminated.

If trees are felled in the winter, when the live sap is not filling the cells, and properly seasoned, the sapwood is visible, but bright and light coloured. If trees are felled during spring and summer when the juices are circulating, the cells contain chemical combinations which are liable to decomposition or to the attacks of fungi. The sapwood of such trees becomes discoloured, turning green or blue, and is unfit for use. At best the sapwood is less durable than the heart. But if perfectly bright and not exposed to variations of humidity in the atmosphere it will last and take a share of the load. That is to say, a 9 inch by 3 inch, showing 1 inch of bright sapwood at the edge, will be stronger than the 8 inch by 3 inch which would remain were the inch of sapwood removed.

So far as internal joinery is concerned, in panels, mouldings, &c, where the element of strength is not important, the problem becomes largely one of appearance or interference with decorative effect. The general practice of to-day tolerates the use of a limited proportion of bright sap for all but the very highest class of work. But very few specifying clauses contain any hint of permission for the inclusion of the smallest modicum.

Then what about knots? The large dead knot is a source of weakness, but the live knot, firmly attached to the rings of living wood, may be regarded as playing its part in bearing stress. The small dead knot, if its dimensions do not break into many of the annular rings, is a negligible quantity so far as strength is concerned. Here again the question of disfigurement comes in.

As to centres, a sound centre is rarely objected to if completely boxed in by the surrounding wood, and is of course inevitably passed in the case of very large carcassing stuff.

Putting all these considerations together, the following were suggested as workable clauses for the regulation of joiners' and carpenters' timber:—

Wood for carcassing or carpentry shall be sawn out of sound, bright, square-edged Baltic or White Sea planks, deals and battens, or Danzig fir, pitch, Oregon or British Columbian pine of similar quality.

The wood for joinery to be Baltic or White Sea yellow, equal in quality to the best Russian or Swedish shipments.

All to be free from injurious open shakes, large, loose or dead knots, or more than a small proportion of perfectly bright sap and thoroughly seasoned.

GOTHIC STYLES IN MODERN ARCHITECTURE.*

IN speaking of the use of the Gothic styles in modern work one must necessarily confine oneself chiefly to dealing with ecclesiastical buildings, because for buildings of the civil class fashion now favours almost exclusively the modern Palladian manner, and this fashion also to a great extent influences domestic work.

That Palladian Classic is alone suitable for modern methods and requirements seems indeed to be generally accepted without question, but the truth of such a view is open to much argument, and certainly its blind acceptance does not tend to the advancement of architectural art.

The late Mr. James Fergusson, in the introduction to his "History of Architecture," gives an illustration of the front of a supposed building. The first section is absolutely plain, like the front of any tenement house in a back street, and he shows it repeated five times, with various degrees of increasing enrichment, in the shape of cornices, pilasters, architraves, arches, balustrades, rustications, &c. The front might be that of a cotton mill, a bank, mansion, or a hotel; and though the first section is nothing but the commonest building, the last or fifth has some considerable pretensions. This fifth section I consider very fairly represents the generally accepted type of the modern method of civil and domestic architectural design. It is not, however, architecture at all, but merely the application of architectural ornaments of a more or less satisfactory character to the front of a building, which building, so far as practical requirements are concerned, would be quite as satisfactory in section 1 of Mr. Fergusson's illustration as in section 5.

Such a method of design, though no doubt recognised in the later Renaissance and modern Classic work, was not the method of the builders of either the Antique or Mediæval schools, where, apart from the ornamental features, the methods of construction, though widely different in the various stages of development, expressed the use, and so governed the form of the building.

Separated from this leading principle of utility (which is not apparently usually accepted in modern work), I do not believe good design can be produced in any style, and certainly not in Gothic, which, as was well said by Pugin, is the art of ornamental construction as opposed to constructed ornament.

This great principle guided the masters of the Gothic revival, such as Sir Gilbert Scott, Street, Bodley, Pearson, Butterfield, and others, in the most successful of their works; and these works will, I feel sure, come to be more justly appreciated when the present fashion for ponderous and clumsy revived Classic Renaissance has had a little time to cool down.

In criticising the civil buildings of the Gothic revival,

* A paper read before the Sheffield Society of Architects and Surveyors by Mr. Temple Moore, F.R.I.B.A.

such as, for instance, in London, the Houses of Parliament, the Law Courts, and St. Pancras Hotel, &c., great allowance must be made for the difficulties the architects had to contend with in the carrying out of work at this time. For instance, among other things, the fashion of the day prescribed as an absolute necessity large sheets of plate glass in all windows, which alone is sufficient to spoil the appearance of any building, besides the desire for a machine-like accuracy in all architectural details, mouldings and carving, which gives to many buildings of this period a harshness which, had the methods of Gothic workmanship been better understood, would have been avoided.

In spite, however, of minor defects, the best of the Gothic revival buildings of this period are full of character and interest, and if the style had been persevered in its various characteristics would have become gradually better understood, and I believe a higher level of architectural art would have been reached than we are at present likely to see in what may be called public buildings.

The departure from the true principles of architectural design seems to have begun in this country with the works of Vanbrugh, whose pompous and heavy version of the Palladian manner has, I think, largely influenced from time to time the popular conception of architecture with us. Its influence is very evident in our more recent public buildings, with few exceptions, and it seems likely with men of the Classic school to cause the gradual obliteration of the much finer traditions of the earlier English Renaissance.

This English Renaissance may be said to have commenced in the reign of Charles I., and to have reached its highest point in the works of Sir Christopher Wren. The best examples of this period are unsurpassed in their particular way in the dignified simplicity of their proportions and details. The influence of this time gave us much charming domestic work of the simpler character, and its traditions remained to a large extent in our less pretentious buildings to quite the end of the eighteenth century. The influence of these traditions was, however, finally extinguished by the window tax and the earlier Building Acts.

The reaction against the utterly commonplace and unworthy buildings of the earlier part of the nineteenth century brought about the first serious attempt to revive the use of the mediæval styles; and I suppose that no one had greater influence in this than the elder Pugin, who certainly had an extraordinary insight into the true principles of Gothic design, based as it was in his case on a thorough study of old work.

Pugin is best known by his ecclesiastical work, and, to name a few examples only, his Roman Catholic cathedrals at Birmingham, Nottingham, and Derby, and the church at Ramsgate, are works of great excellence. The Birmingham church is one that has always attracted me in spite of its two very wretched western spires, but despite its spires this church is a very instructive one, showing as it does what may be done with quite simple materials and design. Externally it is of brick, and is fitted with great skill on to a falling and awkward site at the east end. It is, however, the interior which is the striking part of the building. The scale is, of course, small when compared with many ancient works, but is quite sufficient to give great dignity, and it is certainly one of the best works of its time.

Pugin's connection with Barry in the carrying out of the Houses of Parliament is, I think, now generally admitted, and the detail of much of this fine building certainly suggests Pugin's handiwork. The great fault, however, of this particular work is the over-elaboration of detail, every bit of the exterior being covered with niches and panelling, &c., which, though in themselves often of excellent design, become wearisome by endless repetition. This fault, indeed, is not confined to the Houses of Parliament, but is largely shared by most of our great buildings of late years, quite apart from the particular style in which they may have been designed.

Now I have come to think that this over-elaboration is largely due to people attempting to judge of buildings purely from the mechanical drawings showing them. As you perfectly well know, no building can ever be seen as it is shown on an architectural elevation or section, but the public (and I fear many architects) appear to think only of what the drawings look like. To make an architectural elevation look attractive it has to be loaded with a quantity of details and features which, when translated into the actual building, produces the fussy, restless feeling which is unfortunately the distinguishing feature of most of the architectural work of the last sixty years.

For example, if you will compare the drawings of nearly any old building of recognised architectural merit with a drawing of a modern design, you will at once be struck by the extraordinary difference of the two things on paper. Probably to most people the drawing of the modern building would be the most attractive, the old one would look bare and uninteresting, and the other would look ornamental.

Or again, I believe that if either the Ducal Palace at Venice (I speak of the front or Gothic portion facing the Grand Canal), or, say, Durham Cathedral, both of them in their different ways perhaps the finest buildings of their kind in the world, would, if drawn out to ⅛-inch scale elevations, stand a very poor chance in a modern competition. The assessor and his committee would almost certainly pass them both by as being bald and uninteresting, monotonous, lacking in originality, and so forth.

I feel sure that the great development in the skill of the architectural draughtsman within the last fifty years has hindered rather than tended to improve architectural design, the very natural tendency in these competitive days being to think more about the appearance of the drawing than the design and consequent appearance of the building it is intended to illustrate.

Please do not misunderstand me. I by no means wish to depreciate in any way good, accurate and sound architectural draughtsmanship; it is a real necessity under modern conditions, but it must never be lost sight of that it is merely a means to an end, and not the end itself.

Nor is this overloading the design of which I have been speaking confined to work of the Gothic school; it is quite as noticeable in modern Palladian; for if the draughtsman on the Gothic design runs riot with panelling and pinnacles, his brother on the Palladian design gives you a surfeit of rustications, which I think is possibly even a more wearisome form of—shall I call it?—decoration.

Not, however, content with rustication on the wall surfaces, which would enable you to count every stone in the building if you wanted to, a further development of the same idea has been reintroduced, and finds apparently much favour with the Palladian men—namely, the cutting up of engaged columns into short lengths by square blocks of stone.

It is hard to understand what beauty there can be in such a treatment of a Classic column, except it be with the object of making the drawings look more dotty. The columns of any of the antique orders are among the most beautiful architectural things ever designed, and with their perfect proportions, beautiful mouldings, and the enrichment of their caps, &c., are never likely to be surpassed in their own way. Whether used on a colossal scale in a portico, or in a Sheffield plate candlestick of the best Adams' period, a Classic column is a thing of beauty; but it is utterly unreasonable to cut its shaft into chunks by square blocks, which absolutely contradict and nullify the whole motive of the design.

In a large block of buildings lately erected in London the order (in this case, I think, Roman Ionic) has its shafts cut up for a considerable portion of their height in the abovementioned manner, and the effect is most unsightly, especially when the columns are seen in sharp prospective from below, which must so often be the case in buildings erected in a street.

The general tendency of the modern English Palladian school of design does not appear to me to promise well for the future. An increase in extravagance of design and material, together with in many cases an altogether uncalled-for increase in the scale, of the newer town buildings (notably in London) seem to be its leading characteristics. In scale the newer buildings frequently quite dwarf their surroundings, and the wildness of the design of many of them rivals the stick and rag architectural vagaries of the White City.

There are, of course, honourable exceptions, and one not infrequently sees in works of the domestic class buildings of refined and artistic design which show a careful study and appreciation of some of the best traditions of English domestic work.

(To be concluded.)

A Scheme is being promoted for a Scottish Exhibition of National History, Art and Industry to be held in Glasgow next year. Primarily the aim of the scheme is to raise funds for the endowment of a Chair of Scottish History and Literature in Glasgow University, but buildings, it is estimated, could be constructed at a cost of 30,000*l.* to 50,000*l.*, and defrayed by the sale of season tickets.

Fire Risks in Buildings.

SIR,—As you were good enough to refer to my letter in *The Architect* of February 26, in your article on "Westminster Abbey and Fire Protection," I should like to say that the fact that there are hydrants to which the fire-engine hose pipes can be attached does not afford a satisfactory answer to the question you originally raised. Attention was drawn in *The Architect* "that some of the important buildings in the metropolis were not protected as fully as they might be if advantage was taken of the hydraulic mains of 700 lb. per square inch at their doors." A fire might break out at the Abbey when the engines were occupied at other conflagrations in distant parts of London, and we have to consider this fact, that New York has in parts of the city where there are high buildings abandoned the method of connecting the hydrants on the face of the buildings to the fire engines, and a special system of high-pressure mains has been laid for the sole purpose of fire extinction. After Mr. Wallace's explanation I will withdraw the expression "antiquated," but still think the appliances described are not up to date.

KILLINGWORTH HEDGES, M.I.C.E.,
Consulting Electrical Engineer.

10 Cranley Place, S.W.: March 16, 1909.

[Mr. Robinson, the late chairman of the L.C.C., stated a short time back that the New York fire mains are supplied with 350 lb. pressure per square inch.—ED.]

A. A. Play.

SIR,—Can you spare me a few lines in your correspondence columns to call attention to the fact that the A.A. play is taking place this year on March 24 and 26? My reason for writing is that last year so many people remarked that they did not know anything about it and would most certainly have gone if they had known. We are anxious, therefore, to bring it before the notice of your readers.

Tickets can be obtained from the undersigned or at 18 Tufton Street, S.W.

Thanking you in anticipation for inserting this short letter, I am, yours faithfully, THOMAS W. WATKINS.

11 Old Queen Street, Westminster, S.W.:
March 17, 1909.

[See announcement on front page.—ED.]

GENERAL.

The Royal Commission on Ancient Monuments in Wales, of which Professor Rhys is chairman, will resume its inquiry at Cardiff on March 23. After Cardiff other parts of the Principality will be visited.

Mr. Thomas Brock, R.A., in accordance with his intention announced some time since, has retired from the presidential chair of the Society of British Sculptors, and Sir Charles Lawes-Wittewronge has been elected president, with Mr. Brock as treasurer.

A Select Committee of the House of Lords, presided over by the Earl of Kintore, met on Tuesday to consider the Malvern Hills Bill, which proposes to give the Malvern Hills Conservators definite powers to preserve the hills from defacement by quarrying operations.

M. Bigot, former resident at the Villa Medicis, and winner of the Grand Prix de Rome in architecture, has been commissioned to produce a plan in relief of ancient Rome. M. Clemenceau has made a grant of 25,000 francs for the purpose.

The Dean of Canterbury has issued an appeal to incumbents within the Southern Province asking that each church should make a contribution—"perhaps a single offertory"—towards the 20,000*l.* now required to place the cathedral in a state of satisfactory repair.

The Meeting of the Edinburgh Architectural Association arranged for March 24 has been postponed till an early date next session, in consequence of Mr. Morley Fletcher's absence from town to attend the International Archæological Congress meeting at Cairo.

Mr. Ibrahim Shaik Ahmadi, Fellow of Bombay University and the first Indian F.R.I.B.A., died last month. He was for some years executive engineer of Bombay city, and was subsequently appointed special engineer of the Bombay Improvement Trust.

The Prizes were distributed on the 10th inst. to the successful competitors in the Manchester Society of Architects competitions. They were as follows:—Design for a church tower: Senior prize, F. Cowper; junior prize, E. B. Norris. Design for a timber-framed ventilating turret: Senior prize, W. J. Roberts. Design for a dressing shelter: Senior prize, W. J. Roberts. Design for lych gate: Senior prize, W. J. Roberts; junior prize, E. B. Norris. Prize winner for best work done in School of Architecture classes: Second and third year student, F. Cowper; first year student, H. O. Hill. Session 1908-9—Mr. Ogden's prize, design of a country house: Senior, first prize, Hubert Worthington; special senior prize of 2½ guineas, J. F. Cowper; special senior prize of 1½ guineas, W. J. Roberts; junior prize, E. B. Norris. Design for an entrance doorway: Senior prize, Leo H. Cross. Design for a college of arts: Junior prize, G. Hemm. Design for a country bungalow: Senior prize, L. M. Angus; junior prize, G. Hemm.

The Margaret Stokes Memorial Lectures will be delivered at Alexandra College, Dublin, on Wednesday, March 24, and the two following days at 4 P.M. The lecturer will be Professor W. Ridgeway, D.Litt., LL.D., Professor of Archæology in the University of Cambridge. The subject of Professor Ridgeway's first lecture will be "Ireland in the Bronze Age." In the second he will deal with "Ireland in the Early Iron Age," with special reference to the "Oldest Irish Epic," on which Epic he published a book in 1907. In the last lecture he will treat of "Ireland in the Early Middle Age."

The Cambridge Syndicate appointed to obtain plans and estimates for a museum of general and local archæology and of ethnology on the Downing College site are of opinion that, as the fund amounts to over 10,000*l.*, leave should be asked from the Senate to begin at once the first portion. Some of the rooms will be available for the Cambridge Antiquarian Society. The building, designed by Mr. T. G. Jackson, R.A., will abut on the Squire Law Library, and occupy the vacant ground at the corner of Downing Street and Tenniscourt Road

The Council of the Surveyors' Institution have accepted an invitation from the South Wales and Monmouthshire committee of the Institution to hold the next country meeting at Cardiff on May 20 and 21.

It is Stated that the Very Rev. Dr. Cameron Lees, minister of St. Giles's Cathedral, Edinburgh, and Dean of the Order of the Thistle, has received a letter from Lord Knollys on behalf of His Majesty the King as head of the Order of the Knights of the Thistle, stating that the Knights of the Thistle desired to have a chapel or stalls of their own in the capital of Scotland, that they had given up the idea of having such in Holyrood, and now wished to know if the authorities of St. Giles's would favour the idea of accommodating the Knights in the Cathedral. Lord Leven and Melville has placed at the disposal of His Majesty for this purpose his share of the 40,000*l.* his father left for the restoration of Holyrood Chapel, which sum went back to the family estate on account of the project not begin proceeded with. The sum in question amounts to 20,000*l.* or 25,000*l.*

The Leighton House Committee are raising a sum of 250*l.* for the purpose of acquiring for the public Lord Leighton's first large and important picture, "The Death of Brunelleschi," painted when he was twenty years of age at Frankfurt, where it has remained till now. The work belongs to Dr. von Steinle, son of Professor Eduard von Steinle, Lord Leighton's master [illegible] friend, who has lent it for exhibition in the studio [illegible].

The Northants Education Committee have agreed to the following appointments of architects for new work:—Badby new school, Mr. J. T. Blackwell, Kettering; Burton Latimer new school and special centre, Messrs. Gotch & Saunders, Kettering; Corby new school and special centre, Messrs. Sharman & Archer, Wellingborough; Rothwell special centre, Mr. J. T. Blackwell, Kettering; Silverstone new school, Messrs. Brown & Fisher, Wellingborough; Towcester new school, Messrs. Law & Harris, Northampton.

The Royal Academy of Arts will, on the 23rd inst., elect one Cousins annuitant. Applicants for the annuity, which is of the value of not more than 80*l.*, must be deserving artists, painters in oil and water-colours, sculptors, architects, or engravers, in need of aid through unavoidable failure of professional employment or other causes.

The Architect.

THE WEEK.

ON Wednesday last the Lord Chief Justice, Mr. Justice DARLING and Mr. Justice JELF, sitting as a Divisional Court of the King's Bench Division, gave judgment in the appeal case of the London County Council *v.* the District Surveyors' Association. As our readers may remember, the London County Council, although succeeding to the duties and responsibilities of the School Board, considered that they were not bound to give notice to the District Surveyors or to be subject to their supervision under the provisions of the London Building Act. A test case was tried before Mr. GARRETT, the stipendiary magistrate at the South-Western Police Court, and he decided against the County Council, but stated a special case for the High Court. Their lordships held that although the London County Council did not come within the purview of Parts VI. and VII. of the Act, they did come within the provisions of Section 145. The appeal of the Council was therefore dismissed and the decision of the magistrate affirmed.

AN important decision was given on Friday last in the Consistory Court of London, at St. Paul's Cathedral, by Dr. TRISTRAM, the Chancellor of the Diocese of London. An application was made by the Vicar (the Rev. WALTER FORSTER, M.A.) and both the churchwardens for a faculty to authorise the erection of a rood-screen, the essential feature of which, as proposed, was a rood-beam with a central cross containing the figure of Our LORD, crowned and reigning on the Tree, with the accompanying figures of the VIRGIN and ST. JOHN. That is, in short, the screen was to be a veritable rood-screen. The main point of the learned Chancellor's judgment was to determine whether the rood-screen was an architectural ornament or a church ornament as referred to in the rubric in our present Prayer-book. "And here it is to be noted that such ornaments of the Church and of the ministers thereof at all times of their ministration shall be retained, and be in use, as were in this Church of England by authority of Parliament in the second year of the reign of King EDWARD THE SIXTH." The Chancellor decided that a rood is an ornament of the Church within the meaning of the rubrics, that it is not prescribed by the rubrics, and not necessary or subsidiary to the performances of the Church, and therefore he declined to grant the faculty, notwithstanding that it was urged on behalf of the application that the erection of the screen would materially assist in strengthening the piers of the chancel arch, which had been affected by recent drainage works.

ALTHOUGH half a million sterling is a large sum to raise for any one object in these days, there is good reason to hope, after the meeting held at the Mansion House last Tuesday, that the Shakespeare National Theatre in honour of the tercentenary of the poet's death, which took place in 1616, may become a reality. Enthusiasm was imparted to the committee by the announcement of an anonymous donation of 70,000*l.*, and starting from this encouraging commencement there appears to be a strong probability that we may have in London a repertory theatre which shall do for dramatic art in England what the Comédie Française has done in France.

IN the Newcastle section of the Society of Chemical Industry a paper was recently read by Mr. CHARLES J. POTTER on "Chemical Changes in Portland Cement Concrete and the Action of Sea-water thereon." Some concrete has been found to be injuriously affected by the action of sea-water, and as a result of various experiments it has been discovered that the addition of six parts of red calcined clay to ten parts of the cement clinker before grinding gave the best results and obviated the damaging effect of the sea-water. It has also been found that the action of carbonic dioxide on cement concrete brings about a high degree of induration. Some years ago we analysed some specimens of American hydraulic lime which had been successfully used with sea-sand, and found that this lime contained a high percentage of magnesia and a very small amount of alumina silicate, from which we deduced that whilst ordinary hydraulic lime cannot well be used with sea-sand, a dolomitic lime is not open to the same objection. With regard to the use of red calcined clay in concrete, we have found that burnt clay ballast with Portland cement for matrix produced a concrete which, when examined some twenty years after it had been laid in foundations, was of remarkable hardness and strength. It is scarcely necessary to say that the clay had been thoroughly well burnt.

THE British School at Rome is desirous of undertaking excavations at Malta on the lines of the successful and valuable explorations of Dr. EVANS, this year's Royal Institute gold medallist, and Dr. MACKENZIE at Cnossos, and hopes to obtain thereby results of equal importance. Funds are wanted, and the Secretary of the School has made an appeal for contributions.

SCOTS law is not on all fours, as they say in the Courts, with that of England, but nevertheless the result of the appeal of the executrix of the late WILLIAM MACKISON, borough engineer of Dundee, against the decision of Lord GUTHRIE in the action of Mr. MACKISON *versus* the Corporation of Dundee, is not without interest. Mr. MACKISON, as our readers may remember, was borough engineer of Dundee for some thirty-eight years, during which time he performed many services beyond what he or anybody else, as far as we can make out, anticipated would be within the sphere of his duties when he was appointed. The value of these services he estimated, and no doubt rightly, at 45,000*l.*, but he claimed and sued for 15,000*l.* only. He died whilst the action was in progress, and although the Town Council offered to compromise for 4,000*l.*, this was refused by his trustee, the case was lost, and his estate condemned in costs. The appeal has been no more successful, and has been dismissed with costs. This case is illustrative of what is happening all over the country. Public authorities, in plain language, are robbing the engineering and architectural professions of enormous sums of money. They decide to employ a salaried official, as borough engineer, council surveyor, education architect, or in some such capacity. They appoint a young man, at the outset of his professional career, to whom a fixed salary of some 300*l.* a year or thereabouts, sometimes less, is more attractive for the moment than the uncertainties of private practice. At first he is, at the figure, well paid; the work is not excessive, but it grows. As an instance, when the late Mr. MACKISON was appointed his staff numbered three; when his employment was terminated in 1906 it was eighteen. The salary no doubt increases to some extent, but not to anything like what it should be if it were in accordance with the skill and experience gained by time and study or with the added responsibility, until the unfortunate paid official finds that he is carrying on a practice which, in the ordinary way, would probably bring him in ten times what he receives. He has no redress; like Mr. MACKISON, at his appointment he was bound to give his whole time to his masters, and no matter what the value of his services might be, he can claim no more than his salary, but must be humbly grateful for any little extra honorarium or Christmas-box his employers like to give him. The Dundee Town Council generously gave Mr. MACKISON during his thirty-eight years of admittedly conscientious and unsparing work the munificent additional sum of 205*l.* No wonder at their last meeting they congratulated themselves that they had good reason to be satisfied with the decision. Are the Councils of the Institution of Civil Engineers, the Surveyors' Institution, and the Royal Institute of British Architects also satisfied?

MADRID.*

WHEN one is contemplating and planning a holiday abroad one is thankful to be furnished with a clear and concise account of what is to be seen in the localities to which one's thoughts are inclined as a possible object of pilgrimage, and such guidance is admirably furnished by the Spanish Series of Mr. ALBERT CALVERT. When an architect has left behind for ever his *Wanderjahre*, and can no longer spare time for the delights, the disappointments and the thrills of discovery that go to make up the charm of an exploring tour, he wants to know beforehand where to go without loss of time and with prescience of what he will find. The present volume opens out the possibilities of Madrid, "Imperial y Coronada, muy noble y muy leal y muy heróica."

Madrid is essentially a modern city and has little to show in the way of antiquities as compared with other towns of Spain—Segovia, Toledo, Avila, Burgos, Seville, Cordoba and Granada. It is emphatically not the place for a young architectural student, for a Soane medallist or a Tite prizeman, but for him whose faith is on a sure foundation and whose judgment is sound the opportunities that Madrid affords of studying the work of the seventeenth and later centuries of Spanish architecture are valuable and suggestive. For Moorish work and the *plateresco* period of Spanish Renaissance a twenty-mile journey must be made out of Madrid to the old university town of Alcala de Henares, but the Herreresco, the Baroco and Rococo can be found in the capital city of Spain to quite as great an extent as is wholesome.

The handbook before us is just what is wanted as a preparation for visiting a city like Madrid without the tedium of the ordinary guide-book. After a chatty chapter on the general aspect of Madrid, hygienic and social, we have a sketch of the history of the city from the tenth century to the latter part of the nineteenth, and of the manners and customs of the Court and society. Then a chapter on art in Madrid. This being a book for the Philistine, art, of course, means painting and painting only. VELASQUEZ, MURILLO and GOYA overshadow all other Spanish painters, and it is in Madrid, particularly in the Museo del Prado, that their masterpieces are to be found. Art in Madrid is not, however, confined to painting, but is prominent in remarkable works of the best armoursmiths of Europe, collected in the Royal Armoury, a collection unsurpassed by any other and approached only by that in the Imperial Armoury at Vienna. This collection owes its high position not to Spanish craftsmen, celebrated as were the sword-blades of Toledo, but to the superlative workmanship of famous Bavarians and Italians, notably the COLMANS of Augsburg and the NEGROLIS of Milan.

A sketchy account is given of the architecture and history of the churches and public buildings, as also of the little town of Alcala de Henares to which we have already alluded, and then a tolerably full description of bull-fights and bull-fighters makes up no inconsiderable proportion of the literary part of the handbook. Quite properly, for the bull-fight is the most assertive feature of the life of the Madrileños, and Madrid is the Mecca of every Spanish *torero*. Mr. CALVERT seems to think that a feeling is growing up even in Madrid against the worst feature of the Spanish bull-fight, the massacre by the horns of the bull of the miserable specimens of worn-out horses that are ridden to their death by the *picadors*. The Spaniards might very well learn in this respect from their neighbours in Portugal, where the gallant bull is not killed, and where any horseman who allowed his steed to be even scratched would be hissed out of the ring. Hence the finest horses and the finest horsemanship in the country are displayed in the Portuguese bull-ring, and both horse and bull probably enjoy the sport as much as the man and more than the spectators. There is, in fact, in the Portuguese bull-fight no more cruelty than in a Rugby football match, and the sport is in no way inferior, if indeed it be not superior, to the Spanish form. Even if, to preserve the exhibition of the high skill and courage of the *espada*, the death of the bull still remained the crowning feature of the fight, the introduction of the Portuguese equestrianism would add largely to the interest of the spectacle and deprive it of its most revolting episodes.

We now come to a remarkable feature of this charming handbook. There are 169 pages of letter-press, in large print with wide margins, and 453 pages of illustrations, almost all reproductions of photographs. Of these a large proportion are views of buildings and parts of buildings old and new, and although the scale is too small to admit of serious study of their architecture, they nevertheless gives us an excellent idea of what Madrid has to offer, the formality of HERRERA, the Late Gothic of the Hospital of the Conception or "la Latina" in the Calle de Toledo, the wildest extravagance of the Baroco, as in the façade of the hospital in the Calle Fuencarral, besides the modern work of the nineteenth century. Although HERRERA's work may be formal, it is not without dignity and power, and there is much that is admirable in his designs. The tabernacle in the Escorial Church, executed by TREZZO, although "restored" in 1827, is a very excellent piece of detail.

The Escorial, monastery, palace and tomb, is fully illustrated, so that the reader may form his own independent judgment of its merits or defects, and may or may not agree with the opinion of the author, whose impression can be gathered from these words:—"In its simplicity and hugeness it might easily be mistaken for the work of Nature, not of man. Artistically this is perhaps its sole merit, yet, as I have said, it never fails to awe." This impression is probably the result of the material of the building, grey granite, and the severity of its façade treatment, but what particularly strikes us is the maintenance of what seems to have been a dominant characteristic of composition in the work of the early Spanish Renaissance architects—restraint in the lower portions of their buildings with richness in the upper parts. The façade of the University at Alcala de Henares, included in the illustrations, is an instance of this mode, and is but one of many that may be found throughout Spain. The austerity of the wall treatment of the external façades of the Escorial is, to our mind, an admirable foil and support to the grouping and piquancy of the features that go to make up the skyline. To appreciate the general composition of so huge a building one must view it from a distance, such as the point from which is taken the general view. Mr. CALVERT tells us that the original plans were drawn by JUAN BAUTISTA DE TOLEDO, and the first stone laid in April 1562, and that on the death of the original architect in 1563 the work was carried on by his assistant, JUAN DE HERRERA, and completed in June 1582. But our author says, "The real architect was PHILIP himself." "TOLEDO and HERRERA can have had little else to do than commit the scheme to paper." We should rather say that the designer of the Escorial must have studied the work of BRAMANTE and PALLADIO, and then, influenced no doubt by his studies but without copyism, he has imbued his conception with his own personality, and that the personality of a Spanish architect. For example, the little octagonal temple in the centre of the Patio de los Evangelistas reminds us irresistibly of BRAMANTE's San Pietro in Montorio, and yet it is in no sense a copy, but, we agree with Mr. CALVERT, "one of HERRERA's best works" and thoroughly characteristic of that architect at his best. We are somewhat amused at Mr. CALVERT's stricture on the palace portion of the Escorial, the interior of which he says is "altogether in the style of the eighteenth century, a sufficient condemnation." This reminds us of the story of the missionary who warned the Esquimaux of the fires of Hades—they all wanted to go there. "The style of the eighteenth century" is an attraction for our readers nowadays. The truth is that in the Escorial we have eighteenth-century work devoid of the extravagances of the Rococo.

Numerous illustrations are given of the artistic work

* ***Madrid: an Historical Description and Handbook of the Spanish Capital.*** **By Albert F. Calvert. (London: John Lane, the Bodley Head. 3s. 6d. net.)**

Digitized by Google

of the famous Italian and Bavarian armoursmiths of the sixteenth century, the period when in the last days of armour-clad warriors art in the most extraordinary degree was superimposed on utility. It is in this particular phase of the armourer's craft that the Madrid collection, thanks to the patronage of CHARLES V. and his immediate successors on the throne of Spain, excels all others. Of earlier work "it includes few pieces anterior to the last years of the fifteenth century, and none at all of the fourteenth."

The gateways of Madrid are admirable pieces of architectural design, and so too is the Toledo bridge, whilst the modern work is, as elsewhere, sometimes good and sometimes not, but is usually characteristic. In short, Mr. CALVERT'S handbook shows us that Madrid is well worthy of a holiday visit by English architects. Judging from their works, some of our leading architects have already been there.

ARCHITECTURE: ITS TRUE PRINCIPLES.—VI.

By R. OWEN ALLSOP.

BUILDING MASSES.

TO "mass" is to collect into a body, and the object in architectural composition is the attainment of unity. The ultimate effect of massing in building is to interest by the disposition of parts. All mere creation of *outline* for its own sake is bad. The skyline of a building can never be considered as a primary effect. Intentionally silhouetting reduces the art of architecture to that of fretwork.

Massing may be either general, subordinate, or of detail. Thus we may group a roof and tower, or the parts of a façade, or the foliation of a capital. The art of arrangement—fine grouping—is pre-eminently the art to strive for an architectural design. Good grouping means good outline as a natural result, whereas effective outlines may be cut out of cardboard and silhouetted against the sky. The latter effect belongs more to the scenic painter's art. The charge of mere fretting cannot be brought against such an object as the spire of Antwerp Cathedral, because the beautiful silhouette is derived from skilful arrangement of necessary features. Besides, no one ever *saw* a symmetrical outline in a building, whereas symmetry is the great aim of the fretworker, and from the smallness of the completed object a practically symmetrical view is given to the eye. A *pattern* against the sky is not required in architectural design. Perspective effect destroys any "symmetry" in large objects. The main plea for a well balanced effect of building outline must be based on the supposition that the building is to possess some beauty and interest at a distance. One general description of the nature and requirements of architectural design may be gained by advancing towards a building. Afar off we see interesting outline rising against the sky. On nearer approach the general grouping begins to affect the observer, and what might be called the middle-distance view has, for its base of effect, outline *plus* composition. The nearer we approach the less importance is attached to mere outline. The arrangement of masses becomes of the first importance; nearer still the subordinate grouping interests us, until when we stand beneath the portals outline and grouping, both major and minor, cease to have any value (because we cannot see them) and we become absorbed in the details. Providing that the practical needs —service—of the building are properly fulfilled, we have, if satisfied with our view, from distance to close proximity, been beholding a true work of architecture. If now we start away from a building and recede, we can equally show what is not architecture. Our examination of the detail work may be satisfactory, and the main grouping of parts may be passably interesting; but let it be supposed that as we move off we discover bad major grouping—uninteresting and tame—ugly to the stage of that is revolting, and that when we see the general outline only there is nothing but a monstrously ugly silhouette; then we may fairly say such is not architecture—being imperfect in its nobler qualities. And here we may see that detail of itself cannot be counted architecture, can indeed scarcely be termed architectural, if it has no harmony with the larger mass. Truly, of such a work all the beauty might have been shown in a museum.

Such a composition as last described may well have been produced by one who had no grasp of the whole problem, or by one who had never thought of architecture except of the elevational type or as a mere frame for exhibiting detail. All such detail might have been hung for exhibition on a screen. Assuming that of itself such detail were pleasing, take it away, and what remains? There is a building certainly, just as in the most utilitarian engineer's design there is a building. But there is no architecture. Architecture, then, is pre-eminently a compound. And if a compound, is composed; and, therefore, in the actual composition must reside effect for good or for evil.

In natural scenery and in natural things the universal tendency is towards grouping and the formation of masses. A view over a countryside does not reveal sheep and cattle, trees, clouds and sky mixed up heterogeneously. The clouds group in the heavens, sheep graze with sheep, kine keep to kine; there is a breadth of hill country and broad stretches of marshland, belts of trees of a kind, land here in mass and water there, flights of duck or starling—everywhere the old saw as to birds of a feather applying to all things animate and inanimate, in a wonderful manner when we reflect that we might reasonably expect some intermingling. Generally, this rule is correct; plantations, farmyards, and "happy families" being artificial. All painters in pictorial composition imitate this principle of nature. The essential of the picturesque would be lost by, as it were, putting a landscape into a mixing machine and producing a mass homogeneous in all its parts—that is, having the same amount of bird, beast, tree, water, land, and sky to the unit of surface. The climax of "patchiness" would result. It would seem at times as though a designer of buildings having, say, twenty or thirty fine columns at his disposal, considers that he will do best to eke out his stock, a little here and a little there. To make groups and to mass the groups seems the truer principle. So powerful for effect is massing that painters not only seek groups of like things, but bring together unlike groups, tier behind tier, mass upon mass, as best evidenced in many of TURNER'S great pictures. There are some who complain that they cannot see St. Paul's Cathedral, and would apparently be pleased to find the building standing isolated like a model on green cloth, and to deprive those who have eyes, and see, of numberless examples of magnificent massing, and of the necessity for viewing the building in many places, in sharp perspective, in the manner that WREN evidently intended. Bred on elevations and impossible geometrical representations, the taste for elevation and two-dimension effect persists.

If the architect should be judge as to what constitutes architecture, the artist should say what constitutes beautiful architectural effects. That which the latter abhors seems first of all a rigid, symmetrical, elevational effect and the uprising of isolated masses in bald nakedness. In consequence, in picture-making where the least chance and justification occurs he will group and mass; and this being so it seems necessary that the architect should group parts of a building in a manner that will attract his eye. In his reliance on the principle of placing mass against mass, the artist is strictly following nature. Only when we seriously ponder over this question does the principle of massing observable in nature impress us with some sense of its aspect of infinity. It might reasonably be imagined that the eye would soon weary of endless variety, and that, say, when we beheld a flower it should be placed against a monotonous background and clearly relieved in all its parts. The truth lies at the other pole. A moment's consideration of the exact point shows first that in nature one object is placed behind another in practically endless vista; and, secondly, as shown us by the artist, monotonous background never occurs in

Digitized by Google

Digitized by Google

nature, but as a general rule an object breaks from obscurity into prominence, here emerging from the light and there lost in shadow. If any kind of a rule could be suggested in this matter as affecting the art of architecture, it might be that each relieved object must be *sui generis*—pure and not mixed up, in its form and nature, with parts in a different plane. Impurity seems the one great sin in architectural design. The thundering of one-half the biblical writings—against impurity—may suggest the wrongfulness of impurity in all things under the sun; for unless the abnormal had in itself the seeds of death—or impotency in continuing as a series—weird types would be evolved. And we must consider that, for example, Ionic volutes and pointed arches would be a very weird type indeed.

It might be urged that the matter of massing more affects the architectural artist than the architect. The truth is rather that it is impossible to too much consider the principles of orderly grouping and effective massing of groups. And to this is closely related the principle of concentration; for massing has plainly to do with what we finally call "proportion," since it leads to an interesting contrast of varied sizes and dimensions, linear and superficial. If we construct an arcade, we mass arches, and their ultimate grouping constitutes something that contrasts with a residue—hence brings about an effect in the nature of proportioning. The final outcome is that we have *created an effect* that would have been lost by frivolous patching of the arches all over the façade. The beautiful effects of condensation on a window pane result from grouping, as distinct from the diffusion of water as vapour. In the Gothic style pointed arches are massed; in the Classic, square-headed openings. The principle involved evidently conduces to more power and breadth—more character—in ultimate effect, than if an admixture were made of the two species of form.

(To be continued.)

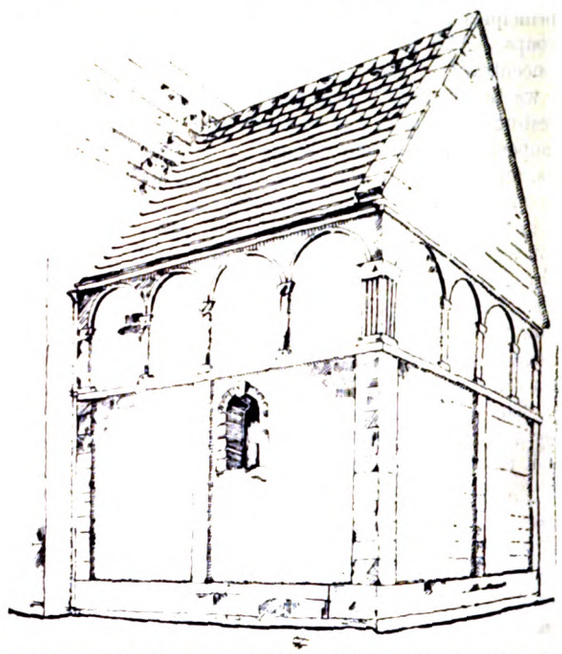
NEW BOOKS.

THE latest addition to the books dealing with sanitary subjects published by CHARLES GRIFFIN & Co., LTD., is "Principles of Sewage Treatment," a translation by Dr. H. T. CALVERT from the German of Professor Dr. DUNBAR, who is Director of the Hamburg State Hygienic Institute. England has the dubious privilege of having rivers which are worse polluted than those of France, Germany, or any other European country. This misuse is traceable to the introduction of the water closet in 1810; although it was not until half a century later that underground sewers were constructed which emptied into the rivers at the nearest possible point. In 1865 the first Royal Commission was established in England to inquire into the pollution of rivers. Four years later a Commission was appointed to consider the disposal of London sewage, and out of it arose the Local Government Board—a body, we are told, which "has exercised a somewhat fatal influence on the development of the problems of sewage disposal and river pollution down to very recent times, not for want of good intentions, but rather as a result of its bureaucratic constitution." Indeed, Professor DUNBAR believes that the past has clearly proved that in this country legislation alone will not achieve the desired results, but that much more may be expected from the formation of a special authority free from bureaucratic influence, consisting of experts in the various branches of the subject, occupying such a position as to command the sympathy of all parties, able to follow any developments, and free to make its decisions. Part I. deals in thirty pages with the historical development of the sewage problem, while the two hundred odd pages of the second part treat of the present position of sewage treatment. Six methods are described for the removal of suspended matters, viz. (*a*) detritus tanks, (*b*) sieves, gratings and screens, (*c*) grease extraction, (*d*) settlement, (*e*) septic treatment, (*f*) precipitation. This long chapter, and the still longer one that follows it on "Methods for the Removal of Putrescibility" are generously illustrated. The author seems as much, or more, conversant with English experiences than with German. His studies have made him convinced that many towns will eventually abandon irrigation in favour of the cheaper artificial biological processes. The book is remarkable for the amount of information that is put into the space, and it is easy to believe the statement that Dr. DUNBAR has consulted, and doubtless thoroughly studied, over a thousand reports and publications dealing with his subject.

Mr. JOHN S. BRODIE, M.Inst.C.E., says in the introductory chapter to his book, "The Ventilation of Public Sewers" (The St. Bride's Press, Ltd., London), that "up to the present time little real progress has been made in the direction of uniform success in the solution of this difficult problem"; although as far back as 1835 a large number of gully traps were formed in the surface-water gullies of the Metropolis. The author takes early opportunity to emphasise his opinion that any scheme for ventilating a defective sewer (*i.e.* one with insufficient gradients or of unsound construction) will only end in disappointment, the only remedy possible being to take it up and relay it on proper principles. Mr. BRODIE is convinced that even perfectly designed and well-laid sewers require proper ventilating arrangements to make them work satisfactorily. Chapter III. is chiefly made up of reports from municipal surveyors and independent engineers on the forms of ventilation by natural air currents. It would appear that the surface gratings in centres of streets are now being replaced by, or used in conjunction with, upcast shafts. The two chapters entitled "Sewer Ventilation by Artificially Produced Air Currents" and "Deodorisation of Sewer Air and of Sewer Gas" give exhaustive accounts of various methods, though they are more descriptive than critical. The author says elsewhere that no reliable information is obtainable to enable a correct general conclusion to be arrived at; each system of sewers must therefore be considered and dealt with on its own basis. Very useful information is given in the chapter on "Comparative Costs of the Various Systems now in Use," including the first cost of installation as well as the charges for working and maintenance. It is estimated that the first cost per mile of sewer ventilated by open surface gratings with 6 inch by 4½ inch shafts against gables of buildings is 57*l.* 15*s.*, and the annual cost per mile is 11*l.*; if 6 inch diameter ventilating columns 30 feet in height placed on lines of kerbs are employed, the figures are given as 108*l.* and 16*l.* respectively. The appendix forming the second half of the book is made up of abstracts of reports, papers, &c., of which the majority were delivered during the last ten years. The great diversity which exists in both theory and practice is well exemplified in the replies to fourteen questions sent out by the Kensington Vestry to thirty-one towns.

"A Text-book of Theodolite Surveying and Levelling" for the use of students in land and mine surveying (London: CHARLES GRIFFIN & Co., LTD.) has been written by Mr. JAMES PARK, who is Director of Otago University School of Mines, New Zealand. It admirably fulfils its avowed purpose of dealing in a simple and elementary way with the course of instruction in theodolite surveying now laid down for engineering and mining students and for candidates for examination as licensed land surveyors in the United Kingdom and in the Colonies. The matter in the pages, when taken with the concurrent field work, is intended to cover a two years' course in surveying.

"Modern Methods of Sewage Disposal" (London: The Sanitary Publishing Co., Ltd.) is a small handbook of less than sixty pages which has been written for members of local authorities and their officials who may lack time and opportunity to study elaborate treatises when it is necessary for their boards to undertake the construction of such works. Mr. W. H. TRENTHAM and Mr. JAMES SAUNDERS, A.M.I.C.E., the authors, can scarcely expect, however, that their condensed account will enable an unaided choice to be made as to the most suitable system. Indeed it is evident that they regard as a *sine qua non* that the sanitary engineer, presumably a consulting engineer, who designs a sewerage scheme will possess a great amount



Digitized by Google

of skill and experience, and be conversant with every part of the management. Consequently their small book is in the nature of a general introduction to more detailed studies, or a guide for earnest representatives on sanitary committees who wish to display an intelligent interest in the matters entrusted to their charge. Mr. Saunders should know the sort of information that is wanted, for he was late resident engineer at the Chichester Sewage Disposal Works. The phraseology adopted is as simple as possible considering the technical character of the subject.

Port Sunlight is one of England's show-places, and has been several times visited by deputations who come to study that economic experiment. There should be an ample sale for "Labour and Housing at Port Sunlight" (London: Alston Rivers, Ltd.). Mr. W. L. George obtained his information from eighty-seven people, only nine of whom were officials, while thirty-one were working men and women, and thirty-six were employés of institutions and others. The three first chapters give a detailed account of the admirable organisation of the scheme; the fourth is entitled "The Village: Topography and Architecture." The illustrations to it are distributed throughout the book and are made up of photographs and a fair number of plans of the different buildings together with a block plan of the entire village. Charming as the township is shown to be, we can readily agree that "the final conclusion as regards the general effect is that it depends to a great extent on circumstances other than architecture; Port Sunlight without its spirit would be only an ideal city, an antiseptic paradise." Unfortunately this leaven has not yet produced any visible effect on improving adjacent villages. Nevertheless it is comforting to look through the pages and to know that the picturesque buildings and far-sighted provision for the workers can be proved in material figures to be profitable to the shareholders themselves. The book is a valuable and interesting study.

The quickening interest in the topography of the Metropolis should receive a fillip from the latest contribution, called "Old London" (London: Alexander Moring, Ltd.), which consists, with one exception, of fifty reproductions of engravings made during the last half of the eighteenth and the first half of the nineteenth century. The handy size of the book (9 inches by 6½ inches) and its cheapness put it on a different footing to some other works dealing with the same subject which are too formidable for the average citizen to purchase or examine. It therefore in no way clashes with the important publications of the London Topographical Society. Each plate is faced by explanatory letterpress giving concise historical notes concerning "the London of our ancestors." An interesting plate is of the Mansion House in 1750 with the "Mare's Nest"—*i.e.* two detached blocks of two storeys each on the roof, and which were used for the servants' accommodation. The addition makes a striking change in the appearance of Dance's building. It is curious to be reminded that as recently as forty years ago the Thames used to wash the southern front of Somerset House. Mr. W. L. McNay, the compiler, has been able to make up an index.

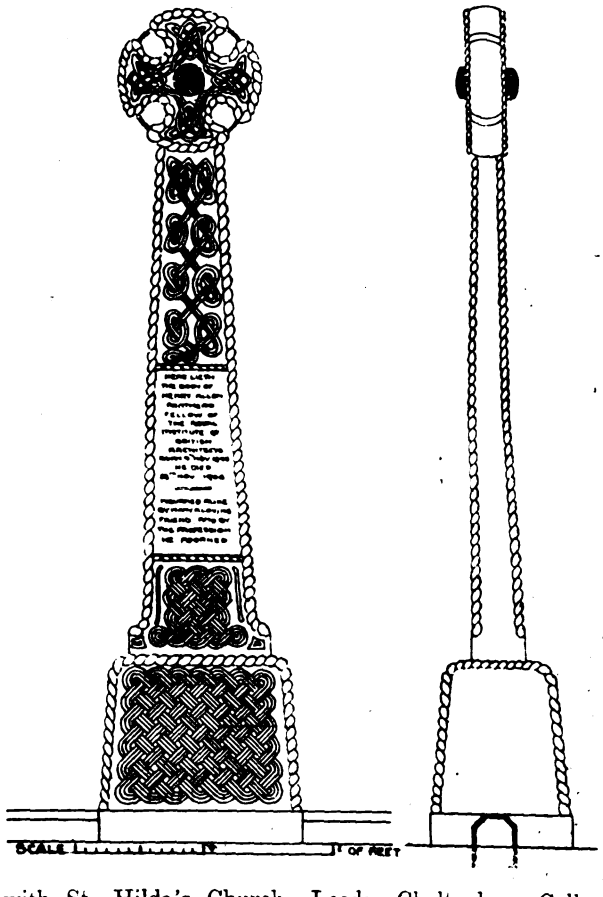
"English Church Architecture, from the Earliest Times to the Reformation." By G. A. T. Middleton. (London: Francis Griffiths, 2*s.* 6*d.* net). Though not to be compared with the writings of Mr. Prior and Mr. Bond, or even with our old friends Parker, Bloxam, Britton, and Sharpe, to say nothing of Sir Gilbert Scott's lectures, this little book is useful as a "first-aid" to the study of our English mediæval architecture by the amateur or even the youthful professional student. Mr. Middleton's meat is not too strong for babes and sucklings, and while he does not attempt to teach everything about English Gothic, what he does teach is put clearly and simply, so that his reader will know something and that something worth knowing after by no means laborious study. We think Mr. Middleton hardly emphasises sufficiently the Keltic influence as a formative element of English architecture. It is rather the fashion to assume that the Saxons, the Danes, and the Scandinavians drove all the Kelts into Cornwall and Wales, but it is scarcely possible that the Vikings swept the land completely of its former inhabitants, and the production even late in the Norman period of such work as that at Shobdon—and this is by no means a singular instance—is evidence of the long continuance of the Keltic influence, while the fact that the square east end and the lateral entrances of our mediæval churches were undoubtedly derived from the Keltic church plan shows how powerful must have been that influence. Mr. Middleton, although somewhat timorously, upholds Parker's theory of the stone-carpentry origin of Anglo-Saxon wall treatment, but we hold that the view of the late Mr. John D. Sedding is far more rational, and that Earl's Barton and similar work is the untravelled English mason's translation of the verbal descriptions or primitive drawings of the Romanesque architecture of Ravenna

brought over by Italian clerics. The subjects of the illustrations are for the most part well chosen, and, by permission of the publisher, we reproduce one as a specimen of the draughtsmanship. The capital from Roche Abbey, fig. 55, is, however, a bad example, and proves that mediæval work was not always good. Jointing is so essentially part of the design in English Gothic that we are sorry to see, as in figs. 43, 44, 46 and 47, geometrical drawings in which the masonry joints are omitted instead of being shown as they should be and as they are in most other cases.

The "Cement Laboratory Manual" (London: Chapman & Hall; New York: John Wiley & Sons) has been prepared for the use of students taking the cement laboratory practice in Illinois University by Professor L. A. Waterbury, who is Professor of Civil Engineering in the University of Arizona. The title of the manual is therefore misleading in so far as it is not intended to serve for laboratories at cement works, but only for those in colleges and universities. An important feature of the book is the part devoted to problems in which the page facing the problem is left blank for the student's notes. For example, problem 1 is for the determination of fineness, and describes the apparatus required, the materials required, the method of operation, and of making up a report. These problems are not intended to serve as instructions for the testing of cement for commercial purposes, but they include all the usual tests.

Mr. Albert C. Freeman, who has already written books on Poor-Law buildings, mortuaries and crematoria, has now completed one dealing with "The Planning of Fever Hospitals" and disinfecting and cleansing stations (London: The Sanitary Publishing Co., Ltd.). The one hundred and sixty pages cover the restricted range of the subject; they are lightened by many text illustrations and by interleaved plans. After Mr. Freeman has intro-

Digitized by Google



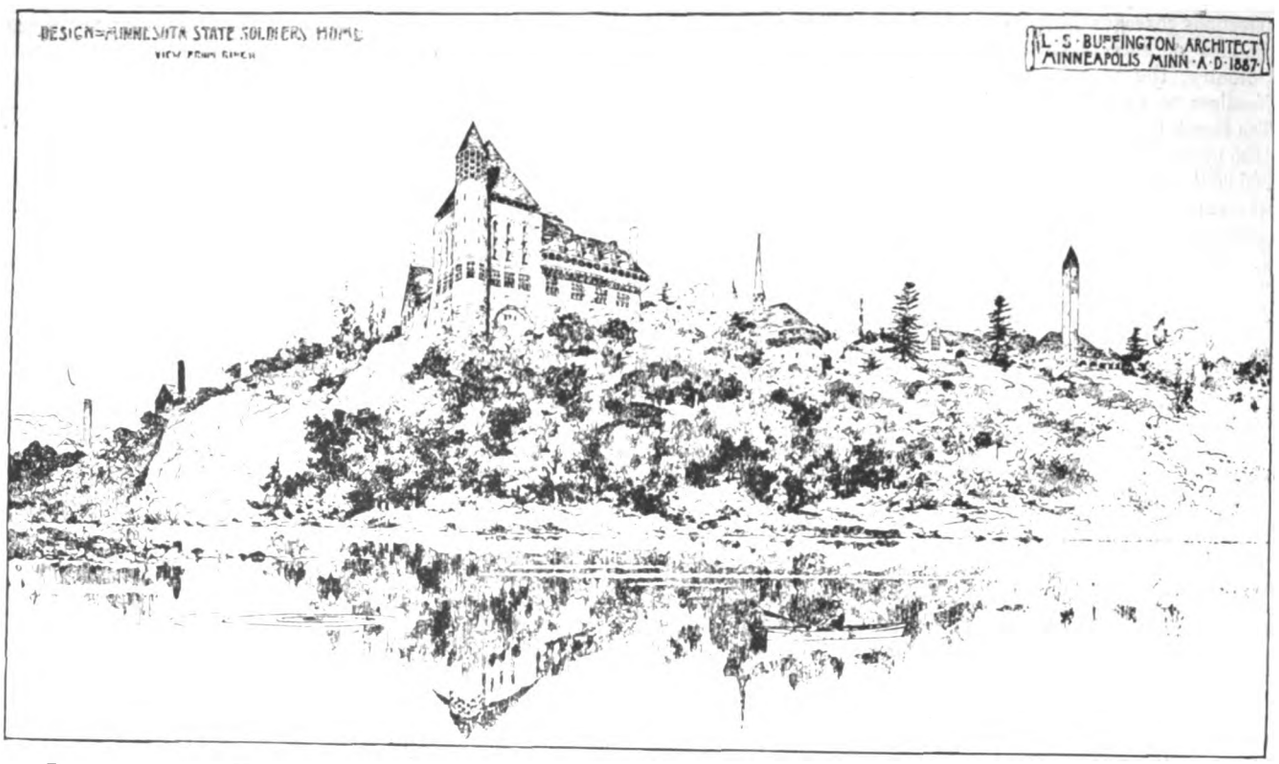
duced the subject as a whole, he deals with particular infectious diseases hospitals, giving briefly the principal features of each. In one or two instances, such as Coventry, the plans are left to speak for themselves. Needless to say, there is a wide difference in outlay. The Brook Fever Hospital, Shooter's Hill, was erected in 1895 by the Metropolitan Asylums Board at a total cost of 286,262*l.*, giving an average cost per bed of 503*l.* 15*s.*; whereas the Crewe Hospital cost 7,000*l.*, or an average outlay of 250*l.* for each of its twenty-eight beds. Mr. T. W. ALDWINCKLE, who designed the hospital at Shooter's Hill, advises the erection of two hospitals for 200 beds each, rather than one for 400 beds, and considers that the maximum number should be 300 beds. The book will prove a valuable and very practical guide to architects and officials who have to design these buildings.

It might seem an exaggeration to say that the castles of England have been neglected by historical-antiquarian writers, but that they are not a great source of attraction is undoubted. Mr. E. B. D'AUVERGNE, in the preface to his book "The English Castles" (London: T. WERNER LAURIE), says that since 1884 only two works of note dealing with the castles of this country have appeared—viz. CLARK'S "Mediæval Military Architecture" and Sir JAMES MACKENZIE'S "The Castles of England." The former is described as "a work written by an architect for architects, and contains a mass of details, valuable enough it is true, but a trifle wearisome, I imagine, to the general reader"; and in addition the theories advanced have been exploded. The author, whose aim has been to hold the balance even between the architectural and historical treatment of his subject, found the division of the work into chapters and the classification of the castles a perplexing and unsatisfactory task. The chapters are arranged thus:—(1) The citadels; (2) Norman and Pre-Norman castles; (3) castles of the Angevin period; (4) the Edwardian; and finally the palace castles. The introductory chapter gives a general review of castle-building from the advent of the Conqueror, who in the first year of his reign summoned Bishop GUNDULF to design the Tower of London, until the sixteenth century, when HENRY VIII. erected Pendennis Castle, in Cornwall, to accommodate artillery. There are now open to writers many sources of information which were closed to their predecessors, for manuscripts and other records have shed a flood of light on the intimate details of mediæval times. Mr. D'AUVERGNE seems to have fully availed himself of these opportunities, and his book has no doubt gained by the experience acquired in compiling his booklet "The Castles of England." This latest work might perhaps have been with advantage more profusely and better illustrated. Almost without exception the plates are small reductions of old engravings in which the "setting" has been of more importance than the castle which gives the title. But the publisher has brought out a highly useful complement to his Cathedral Series.

"The Everyday Uses of Portland Cement" (London: The Associated Portland Cement Manufacturers (1900), Ltd. 1*s.* 6*d.* net). It is suggestive of the universal use of cement when a book is published with the primary object of educating the non-technical public in its uses and of dealing with the domestic side of the material. The booklet, however, contains information that will be valuable and new to many who might be unwilling to class themselves as lay readers. It was impossible to exclude altogether mathematical calculations, but those few that are given should not frighten anyone. The book is divided under the following headings:—Portland Cement, Aggregates, Concrete, Memoranda for Concrete Users, Workmanship, Reinforced Concrete, Concrete Blocks and Moulded Concrete, and Various Uses of Concrete. The latter chapter gives, amongst other things, illustrated directions for making fence posts, paths, steps, water troughs, cisterns, cow houses and piggeries, fruit houses, greenhouses and sheds—all of which must arouse the interest of the farmer or estate owner. In addition some ten pages are devoted to "Concrete on the Farm," with several photographs of work carried out a few years ago at Borris, co. Carlow, and at Great Canfield, near Dunmow. But this is rather an inducement for the lay reader to diligently study the booklet than an essential part of it. The most instructive chapters are those which precede it. The publishers conclude with a leaflet which is to be filled in by those who desire to receive a free copy of any supplement that may be issued. The booklet should fulfil a very useful purpose in affording in simple language an excellent account of Portland cement and of its ubiquitous offspring, concrete.

MALPAS CHURCHYARD CROSS, MONMOUTH.

THIS cross, composed of Irish limestone, has just been placed in Malpas Churchyard, Mon., to the memory of the late HENRY ALLEN PROTHERO, F.R.I.B.A., of Cheltenham, by his brother, Mr. F. PROTHERO, of Malpas Court, near Newport, Mon. The late Mr. PROTHERO was at one time Diocesan Surveyor for the Archdeaconry of Monmouth. This name is associated



with St. Hilda's Church, Leeds, Cheltenham College Chapel, and the tower of Wrexham parish church. He built and restored a large number of churches throughout South Wales. The cross was designed by Mr. G. E. HALLIDAY, F.R.I.B.A., of Cardiff, and executed by Mr. W. CLARKE, sculptor, of Llandaff.

The Cuckfield (Sussex) Rural District Council have decided to use all British granite for their road repairs this year, it being proposed to use Penmaenmawr, Forest of Dean, Mendip, and Scotch granite in preference to foreign granite. The Council's district is a wide one, and the granite contracts will amount to about 5,300 tons.

At the Royal Institute of British Architects on Monday a lantern lecture will be delivered by Mr. M. H. Spielmann, F.S.A., on "British Sculpture of To-day," in place of the paper announced to be read by Sir Aston Webb, R.A.

Mr. H. B. Pollard, surveyor, has removed from 13 Henrietta Street, Covent Garden, to No. 5 Lower James Street, Golden Square, W.

PERSPECTIVE BY HARVEY ELLIS FOR SOLDIERS' HOME ON BLUFF OVER THE MISSISSIPPI, NEAR MINNEAPOLIS
L. S. BUFFINGTON, Architect.

NOTES AND COMMENTS.

HARVEY ELLIS in the last quarter of the nineteenth century was in the United States as prominent a personality amongst architectural draughtsmen as HERBERT RAILTON or RAFFLES DAVISON has been amongst ourselves, and, like our own artists, almost founded a school of draughtsmanship. Almost, but not quite, for, however numerous their imitators, the works of these three men could not impart their individuality to the copyists, who, as always, picked up the peculiarities rather than the personalities of those whom they attempted to follow. The *Architectural Review* (Boston, U.S.A.) contains an appreciative sketch of the life and work of HARVEY ELLIS, illustrated by many examples of his genius, one of which we reproduce, interesting, we think, not only as a specimen of draughtsmanship, but as an example of modern American architecture.

THE case of VINCENT *v.* SKARDON and SELMON seems to be a curious one. The scene was laid in Plymouth, and Mr. J. H. VINCENT, who was, according to the report, described by counsel as "young and enthusiastic," seems to have been clever and capable of filling many parts, for he negotiated the purchase of a site by a syndicate of which he was a member, prepared designs for a building at an agreed fee of 5 per cent. on the estimated cost, superintended its erection not only as architect, but as builder, and acted as expert witness in a successful action against purchasers of the building, who were dissatisfied with their bargain. Although the syndicate made a profit of nearly 50 per cent. on the transaction, the remaining members objected to Mr. VINCENT's claim for payment as builder and expert witness. The jury gave Mr. VINCENT a verdict for more than he claimed. The moral is that legally an architect may, in partnership with others, be his own employer and still claim and receive full payment for his services as architect, builder, or anything else.

THE near approach of the date 1911, when the National Telephone Company must transfer their business to the Post Office, has suggested that the Company must be on the verge of dropping constructional work and dismissing the staff of that department, but the Postmaster-General in the House of Commons pointed out that the Company must continue constructional work for the normal growth of their system between now and the termination of their license, and that although he could not compel the Company to replace obsolete or worn-out-plant, the condition of the plant will form a material element in fixing the price at which the Post Office will purchase. Our personal experience is that the Company is at the present moment keener than ever on keeping the plant in good condition and on getting new business.

WHEN the Philistine begins to talk about ventilation he generally makes a mess of it, and the First Commissioner of Works scored easily over his interlocutor on Wednesday in last week, when yet one more attack was made on the ventilation of the House of Commons. Forty members are laid up with influenza and the majority of them, said Mr. PIRIE, attribute their illness to the bad ventilation of the House; therefore would the First Commissioner consider the desirability of a more natural system? Mr. HARCOURT pointed out that the proportion of members attacked was not larger than in other buildings and professions which are subject to the most natural ventilation, and in reply to further heckling on the topic of the Committee of 1903, scored again by stating that the Committee made a large number of recommendations, all of which he had carried out.

WE think the present President of the Local Government Board can be trusted to use any power he possesses to squash the vandalism of the Windermere Urban District Council in their proposal to establish a sewage farm on the shores of Lake Windermere between Bowness and the Ferry.

COMMENDATORE BONI, the famous archæologist, has proposed to the Italian Minister of Education that the vacant nunnery on the Palatine, near the Villa Mills, shall be converted into a museum for housing casts of the principal busts scattered about Italy, and thus form a supplement to the Forum Museum and Library now being established in the former convent of S. Francesca Romana.

THE EDINBURGH LIFE ASSURANCE COMPANY'S NEW OFFICES, GEORGE STREET, EDINBURGH.—BOARD ROOM—PUBLIC OFFICE.

IN 1823 the Edinburgh Life Assurance Company commenced business in the "Interim Office," No. 24 George Street, which site adjoins that of their recently completed head office, 26 George Street and 53 Hanover Street, Edinburgh. The architect being of opinion that the rounding at the corner of the site would be detrimental to the appearance unless vigorously treated, it was decided to introduce a dome of such diameter as to make it a marked feature. The dome rises to a height of 100 feet, its diameter at street level being 34 feet. It is surmounted by a bronze figure, "Prudence," the work of Mr. P. PORTSMOUTH, A.R.S.A. The base of the building is of grey unpolished granite. Above the granite, the ground floor is treated with plain rustication so as to give strength for the support of the columns which rest on it, and are carried up through the two storeys above. The company's public office measures 54 feet by 45 feet, and in it are four handsome pillars in Pavonazzo marble supporting the upper floor. The height of the ground-floor storey had to be made very considerable so that windows of adequate size could be introduced. There is an attic floor, lit by roof lights, for use as studios. The board-room on the first floor is panelled with figured Utrecht velvet, removed from the old board-room, where it had hung for sixty-four years, and is as good now as in 1844. The remaining part of the first floor and the floors above will be available for chambers and offices to be known as the Edinburgh Life Chambers. Owing to the difficulty of getting good weather-stone of satisfactory colour it was decided to use Portland stone. It was shipped direct from the quarries to Leith, and was worked in Edinburgh. The building is constructed throughout with steel stanchions and floors of reinforced concrete. The drum of the dome is made of steel and concrete, and the dome itself is covered with copper. The architect is Mr. J. M. DICK PEDDIE, 8 Albyn Place, Edinburgh.

THE RETREAT, LLANDAFF.

THIS house has just been erected in the city of Llandaff, situate about two miles from the county borough of Cardiff. The walls are of brick cement rough-casted. All the external dressings are composed of granolithic. The barge boards, half-timber gables, and shoots are

painted black; the rest of the woodwork is white. The house was designed by Mr. G. E. HALLIDAY, F.R.I.B.A., of Cardiff. Messrs. SYMONDS & SONS, also of Cardiff, were the contractors.

DINING-ROOM, WEST HALL, BYFLEET.

THIS dining-room, built for Mr. F. C. STOOP, measures 40 feet by 20 feet in addition to the large ingle shown in the illustration. It is panelled in oak to the height of 9 feet, and has an open oak roof with dormer lights along both sides. At one end an oak sideboard is worked in with the panelling, and at the other end are windows opening into a conservatory. The stone for the frieze, arch, and windows was obtained from Ham Hill. The builders were Messrs. J. PARNELL & SON, of Rugby, and the architect Mr. G. L. SUTCLIFFE, A.R.I.B.A., 17 Pall Mall East, London, S.W.

THE UNITED COUNTIES BANK, BRISTOL.

THIS building stands upon the site of the old Bristol Penny Bank in St. Stephen's Avenue, and faces the church of St. Stephen. The material employed for the façade was Monk's Park Bath stone, the carving being entrusted to Mr. GILBERT SEALE, and the wrought-iron gates to entrance and the window grilles to Messrs. GARDINER & SONS, of Nelson Street. The greater portion of the ground floor is occupied by the branch of the United Counties Bank, Ltd., and comprises a banking hall, measuring 40 feet by 27 feet, directors' room, manager's room, with the usual strong-rooms and lavatory accommodation. The large public space has been divided by a mahogany glazed screen, through which Messrs. A. TRAPNELL & Co.'s offices, on the first, second and third floors, are approached by a mahogany staircase, the second floor including a board-room, measuring 25 feet by 21 feet. The building has been effectually heated on the low-pressure hot-water system by Messrs. CRISPIN & SONS, of Nelson Street; while the electrical installation was entrusted to the Sphere Electrical Company, the fittings being supplied by Messrs. VERITY. The whole of the building work has been carried out by Messrs. C. A. HAYES & SONS, of Thomas Street, under the supervision of Mr. W. H. WATKINS, A.R.I.B.A., of Provident Buildings, 15 Clare Street, Bristol.

THE BLACK LION INN, TRENT VALE, STOKE-UPON-TRENT.

THESE drawings illustrate work that has been carried out at an old hostelry much out of repair, and a portion of which, from about the double gable end to the second chimney, caused a serious obstruction at the junction of two main roads. It was desired to keep up as much as possible of the ancient portion after the removal of the obstruction, but to retain the old style of inn. Most of the exterior has been finished in rough-cast, the lower portion of new front in red Accrington bricks 2¼ inches thick, and the roof in red brown tiles. The whole has a pleasing effect. The property belongs to a brewery company. Mr. J. BEARDMORE is the architect.

RESIDENCES, CASTELLO AVENUE, PUTNEY.

THESE residences are now in course of erection at a cost of 2,000*l.* the pair, from the designs of Mr. ALFRED E. NIGHTINGALE, architect, Putney, under the superintendence of Lord WESTBURY's surveyor, Mr. J. C. RADFORD, A.M.I.C.E., Putney.

The Sub-committee of the Exeter City Council recently had before them the elevation and sections of the proposed Day Training College and University College extension buildings with specifications, the approximate estimate of cost being:—Day Training College—According to plans and specification, including heating, lighting, and architect's and quantity surveyor's remuneration, also including 200*l.* for fittings (*i.e.* desks, &c., in class and lecture rooms), 5,950*l.* University College extension—According to plans and specification, including heating, &c., as above, also including 450*l.* for fittings in laboratories, &c., and class-rooms, 8,300*l.*; total, 14,250*l.* The plans and specifications were approved.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

The SECRETARY announced that the last spring visit, fixed for March 27, would be to the engineering works of Messrs. Richard Moreland & Son, Ltd., Silvertown. The directors, it was stated, have kindly arranged to have the machinery working, so that members of the party may see the various iron-casting processes.

The visit of the Association to the Building Trades Exhibition, Olympia, will take place on Saturday, April 17, at 3 P.M.

On the motion of the PRESIDENT, a hearty vote of thanks was passed to the Royal Institute of British Architects for its eighteenth annual grant of 100*l.* towards the A.A. education scheme.

Mr. J. A. MARSHALL read the following paper, entitled—

A Lesson from the Past.

Quite recently I came across an interesting collection of rare old books on architecture; they were in poor condition and it was not an easy task to determine their age, but after a careful examination, in the manner of the seasoned bibliophile, I had no hesitation in ascribing most of them to those enterprising publishers who flourished in London at the beginning of the twentieth century of our era. Among these books was one on "The Five Orders," this well-worn subject being treated in what was then quite a new way, with the object, I suppose, of giving to it a new lease of life. In another an attempt was made to throw some light on the strange obscurity so long associated with the ancient cathedral builders of this country. Others did the same for the temple builders of ancient Egypt, Greece, Italy, and these were embellished with conjectural restorations that rivalled in dexterity the efforts of a Cuvier or an Owen in another department of research. Others, again, illustrated every phase of the Renaissance; while still another, modest in size if not in subject, gave a comparative description of the architectural styles of all the ages. Besides these I found elaborate and exhaustive monographs, and, most entertaining of all perhaps, huge volumes of designs by the leading architects of that day and by many others who apparently were not so distinguished.

Judging from the publishers' advertisements that encumbered some of these books, we may, I think, safely infer that the age was one of considerable literary activity on the part of many whose calling or profession was essentially practical, if not technical, in its nature. There was evidently a widespread demand for information, in a handy and entertaining form, on subjects that had merely a superficial relation to the practice of architecture; and this demand was partly met, if not satisfied, by such works as those I have referred to, and also by the regular publication, at short intervals, of dissertations, criticisms, news, lectures. I feel sure you will pardon me for expressing the satisfaction I felt at my recovery of some fragments of this ephemeral literature of the twentieth century when I explain that I had already taken some interest in the remains, scanty though they are, of the buildings erected at that time in this country. In looking over these I had not failed to note the marked evidence they bore of that practice of selecting from and adapting the traditional styles of the past, termed "eclecticism"; they betrayed an extraordinary acquaintance with the outer aspects of the buildings of all time; yet it was clear the architect was invariably embarrassed by conditions and requirements more or less opposed to any recognised style, and his efforts too often lacked coherency and expression.

I have said the architectural remains were scanty for so prolific an age. Buildings extending for miles—yes, hundreds of miles—had once proudly reared their palatial fronts in the cities and the towns, but of these few vestiges are now to be seen; they have suddenly collapsed, as if by seismic disturbance or some more subtle agency; certainly there are no signs of that slow decay we associate with sound construction; and I was quite at a loss to account for this until I discovered that the work of the architect has been entirely dependent for support on that of the engineer; it had had no inherent strength, it did not express the construction; it was a mask, aiming at deception, yet never succeeding. Clearly the term "architecture" in this connection is a misnomer.

Science, that most progressive department of man's activity, was in direct conflict with art, as that term had long been understood; like the canker in the rose, its insidious encroachments could not be suppressed; new systems of construction—not amenable to any style of the past—had arisen almost without warning, and the older methods were becoming as obsolete as the sedan chair of Queen Anne or the *Fighting Témeraire* of Trafalgar.

Now, in case you should think these remarks are based on the vain imagination of the antiquary, permit me, in support of what I have said, to read to you an extract from a contemporary newspaper—a quite genuine copy, I may say, notwithstanding the pinky freshness of its complexion:—"The construction of this important building is being rapidly proceeded with. The most interesting point is that ferro-concrete is being used throughout. As was recently announced, the London County Council will shortly apply for Parliamentary sanction of amendments to its building by-laws, which will then, for the first time, permit the construction of buildings entirely of ferro-concrete. The Government, however, is exempt from the existing regulations, and are adopting this novel form of construction in their latest buildings. There will be a remarkable saving in space. For example, the retaining walls are only 7 inches thick instead of 7 feet, as would have been necessary for brick or stone. The continuous foundation slab upon which the whole of the building will rest is only 5 inches thick, but is so ingeniously reinforced by steel that the pressure over the whole area is absolutely uniform. The staircases and landings are entirely without vertical supports, but are simply cast in ferro-concrete and let into the wall; only an earthquake would make them tremble. The architect was anxious that certain parts of the building should be unimpeded by columns and stanchions, as would have been inevitable had ordinary methods of construction been adopted. The use of ferro-concrete, however, has made it possible to build a part of the upper storeys as a cantilever, projecting about 15 feet beyond their supports. The roofs will be flat, and upon them will be constructed four large shooting-ranges, as a precaution against assault by those representatives of the 'gentler sex' that now harass the Government. Members of the Council of the Royal Institute of British Architects are keenly interested in the work."

Now, ladies and gentlemen, I think you will agree there is nothing in the architectural descriptions of either Vitruvius or Pliny more remarkable than this, and it would be idle for us to speculate on the appearance of such a structure; that must be left to other commentators. It may, however, interest you to learn that the "Royal Institute of British Architects," referred to in the last line of the text, was a society established in the early part of the preceding century, the main objects being, I believe, to encourage the advancement of architecture and the interests of the profession generally.

At that time it was open to anyone, irrespective of sex, nationality, credentials or even qualifications, to practise in this country as an architect, if only he or she could find a client to bear the cost of the experiment. This principle, or policy, if you will, of "the open door" no doubt led to some abuses, but it must also have encouraged latent talent, and the young aspirant was then as free to soar into the realms of glory as the painter, the sculptor and the musician are at the present time. "Design in beauty, build in truth" was the watchword of the Institute, and if a man could do this he was, in all essentials, an architect, whether equipped with the diplomatic ægis or not. But when the Government of that day adopted a system of web-like tenacity for important public buildings, in direct opposition to all preconceived methods of construction, caring just as little for out-of-date "essentials in architecture" as did the constructors of a *Dreadnought*, then your professional ancestors became "keenly interested."

And this need not surprise us, for were not millions of money waiting to be spent on similar projects as soon as the building by-laws had been amended? Did not the intruder give promise of a new style, that might perhaps some day become universal and be regarded as the cosmogony of the arts? It was impossible to believe that the death-blow of architecture had been delivered; the faith in its vitality was too deeply rooted for that in the various colleges, academies, institutes and associations established under royal patronage to further its advancement. As I have suggested, the climax did not come entirely without warning. The use of iron, as formulated by the rolling-mill, had been tolerated for years, though incompatible with window recesses and thick walls, and your predecessors had thus gradually become inured to that feebleness and slightness which culminated in the extreme tenuity of the twentieth century.

Ladies and gentlemen, it is very far from my wish to cast a gloom over this meeting by harping on this melancholy aspect of the past; I would rather—in closing the first part of this paper—suggest that the architects of those days were not entirely lost to virtue; they still held that truth was beauty, and beauty, truth, but unfortunately it was not always in their power to perpetuate these qualities in brick and stone.

Part II.—It is well stated in your curriculum that "the growth and development of the various phases of historical architecture have arisen mainly through constructional and actual necessities, modified by varying social conditions and the material available."

In following this development you will find that, although historical architecture has its phases of incipiency, maturity and decadence, yet throughout the ages there was a distinct and uninterrupted advance in the science of building, an advance that was as little affected or impeded by ornamental art as is the tidal ocean by the undulations on its surface; and your attention cannot fail to be arrested by those brilliant achievements in constructive skill that stand conspicuous and unapproachable amid the ever-widening stream of architectural activity.

Thus in the fifth century, when the religious zeal of the Emperor Justinian urged him to build the finest church in the world, the result was a sudden expansion—almost to the bursting point—of the crude principles of pendentive vaulting. In the twelfth century the constructive expedients resorted to by our own Wren were dimly, yet surely, foreshadowed in the Baptistery at Pisa. In the fifteenth century the citizens of Florence, in their religious pride, surmounted their cathedral and the whole city with the largest dome in the world, built on a principle for which there was absolutely no precedent beyond the obscure crudity of the Roman Pantheon. A century later the Roman pontiffs aimed at something still more daring, and at St. Peter's the massiveness of the Florentine dome is sustained by the buoyancy of the Byzantine. And finally, in the seventeenth century, Sir Christopher Wren, for the citizens of London, produced the greatest artistic effects by a novel and skilful disposition of the slenderest materials.

If you turn to the Gothic period you will find the continuity of the advance perhaps still more marked. During the early stages the statical conditions are abundantly maintained in the sturdy proportions of the design. Later, this timidity gives place to a more economic adjustment of the various parts on a grander scale, until all redundant material is eliminated and the structure may be said to present a diagrammatic illustration in stone of the strains and stresses. Finally, this open sincerity is succeeded by an artificial display of the mason's craft, as meretricious and as ingenious as it is splendid. Instances of these phases are well known to you. As intimated in the first part of this paper, the historian and the archæologist have very kindly traced for us their evolution. Due chiefly to varying social conditions, the mutation was generally a matter of slow time and there was nothing startling about it; but when a great calamity occurred—like the plague of the fourteenth century, which swept away more than one-half of the four millions who then formed the population of England—the thread of tradition was somewhat weakened, and the succeeding outburst of the mason's skill at Gloucester may, we are told, be regarded as something remarkable. The gossamer-like veiling that was then spread over the venerable features of the Norman choir and projected right through the apse compels our admiration, and the audacious interference is condoned in view of the independent expression it ultimately assumed in the lady chapel beyond, and later in the chapels at Windsor, Cambridge and Westminster.

(To be concluded.)

JOHN CARR, OF YORK, ARCHITECT.

BEFORE the Leeds Philosophical and Literary Society a lecture was delivered last week by Mr. Sydney D. Kitson on "An Eighteenth Century Architect: Carr, of York."

John Carr, of York, said the lecturer, designed practically all the large buildings which were erected in Yorkshire during the last half of the eighteenth century, besides many outside the borders of the county. In fact, he shares with Wood, of Bath, who was also a Yorkshireman, the distinction of being the greatest architect of his time who practised outside London. From 1750 to 1800 was a dull time in the annals of English architecture. Carr was content with the traditional language of design as he found it, and he reflected in his buildings the ideas and limitations of the age in which he lived. From the Middle Ages right down to the end of the eighteenth century there was a living building tradition, learnt in the workshop and on the works, and independent of drawing and books. Carr was one of the last exponents of the traditional manner. His work, although it was frankly dull, satisfied his generation, as was shown by the fact that he left a larger fortune than had ever previously been made by the practice of architecture. The son of a mason, he was also the grandson and the great-grandson of stonemasons who had practised their craft in Horbury, near Wakefield, for more than a hundred years. In 1750, before he was thirty, Carr left Horbury and settled in York. It was on the racecourse at York that he found his first opportunity, for in 1754 he designed and built the grand-stand on the Knavesmire, a work originated by two young Yorkshire noblemen, Lord Carlisle and Lord Rockingham. The grand-stand—a fine work of Palladian design—was paid for by the issue of five-guinea admission tickets.

Although Carr was responsible for a good many public buildings, it is as a designer of houses that he is chiefly known. His earliest house, so far as can be ascertained, is Arncliffe Hall, near Northallerton, built in 1753. This is the type of house he built for the country squire or the successful tradesman. The other type he used consisted of a central block with two balancing wings, which he built for the great noble or the merchant prince. The work by which he is perhaps best known came to him in 1759, when he designed Harewood House for Mr. Edwin Lascelles. Harewood took twelve years to build, thus showing the homely way in which the employers of the period were content to move. Unfortunately, the building was much altered eighty years later by Sir Charles Barry, who added attics to the wings and a high balustrade to the central block, removing at the same time the columned portico in the centre of the south front. As originally designed, it was well proportioned and as free from affectation as it was from originality.

GOTHIC STYLES IN MODERN ARCHITECTURE.*

(Concluded from last week.)

TURNING to modern Gothic work, this is now almost entirely confined to ecclesiastical buildings, but with the exception of the cathedral in Liverpool no very large new work of this kind has been commenced of late years. There are, however, a great number of parish churches being built all over the country, owing to the rapid increase of the population and consequent growth of the towns. These buildings are usually of no architectural interest, which is partly due no doubt to the necessity in most cases for great economy; but what is so deplorable is that the architects of them generally show very little knowledge in planning, arranging, and designing, and no motive of economy excuses this want. Rather does the need of economy demand a greater knowledge and skill.

Now I believe this lack is almost always due to a want of real living interest on the part of the designers of these buildings in the work they are doing, so that they are content for the most part with a constant lifeless repetition of a set of stock patterns, so to speak. But I can assure you that if there is to be good modern church architecture, it can only be obtained in one way—viz. by a thorough and a constant study of ancient examples and methods. As you know, there are plenty of examples of ancient ecclesiastical work of a severely simple and economical character as well as of the more magnificent and costly sort, but it is surprising how little attention these buildings receive, and I am convinced that the very weak and unsatisfactory character of so much of modern church work is at bottom due to this neglect.

The ordinary modern church almost invariably follows one set type, which is, roughly speaking, that of a nave with low lean-to aisles, a clerestory of very stunted proportions, a short, stumpy chancel rather lower than the nave, with possibly a chapel on one side of it and an organ-chamber on the other. If there be a tower, it is usually put on one side of the nave or chancel, a position given it, I suppose, with the idea of obtaining what is thought to be a Gothic irregularity of outline. I may remark in passing that I do not say a tower may not sometimes be advantageously placed at

* A paper read before the Sheffield Society of Architects and Surveyors by Mr. Temple Moore, F.R.I.B.A.

the side of a building, as, for instance, in the charming little church of Skelton, in Cleveland, one of the best churches done by the late Mr. Johnson, of Newcastle; or in Mr. Bodley's church at Chapel Allerton, near Leeds; besides many other examples ancient and modern. But where this treatment has been adopted successfully it is invariably due to some special circumstance connected with the site or position which fully justifies a departure from the normal place of a tower in a parish church—namely, the centre of the west front. But to return to the common type of modern churches, which indeed has been little varied during the last thirty-five to forty years, and which is as a type surely as uninteresting and unsuitable one as could have been pitched upon, I can only suppose its popularity is due to the fact that it does not require much study or thought, and that it can be produced at a comparatively low price by being thinned down to the utmost permissible limits in its construction.

It is true that buildings of this type are not quite the same to-day as they were twenty-five or thirty years ago. Now the style is generally supposed to be some form of the late English Gothic, instead of being as formerly more or less of a caricature of French thirteenth century, and the east end now frequently finishes in an apse. Possibly there may be some little gain in this, but not much, for we still have the ugly red-brick interior, "relieved," as it is almost always described, by dressings of Bath stone, the thin weedy columns, and sprawling arches. The north side of the building almost invariably is an exact counterpart of the south, except for the chimney of the heating apparatus. The pitch pine and the gaudy, vulgar metalwork of brass or iron, the cathedral glass, which has lately started a development of its own, of wriggling patterns of sickly pink and green, suggesting a wall paper of the "new art." It is true that the coloured tile reredos suggestive of a lavatory has disappeared, and with it the stone pulpit, or parson cooler, as Sydney Smith called it. Their place has been taken, however, generally by hardly less unsatisfactory woodwork from the ecclesiastical furniture-shop, real pastry-cook's Gothic.

It is also true we miss now the striping of the internal walls with black and white bricks (a fashion taken from the peculiar methods of the late Mr. Butterfield and which was formerly highly popular), the polished columns of Aberdeen granite or marble, and the ponderous caps carved with rude representations of fruit and vegetables. These have given place to stone pillars and moulded capitals, but more often than not very ill-designed; and when all has been said, the ordinary modern church is mostly a dismal thing.

I do not think that the foregoing is by any means an unfair description of nine out of every ten modern church buildings, and we cannot wonder at the contempt that is frequently expressed for modern Gothic work, or at the curious remedies one sometimes sees suggested.

I noticed, for instance, a letter in one of the Church papers the other day suggesting the use of ferro-concrete as a material, and neo-Classic (whatever that may be) as a style, for producing good inexpensive church buildings. The former would certainly not be economical under present conditions in this country, though I believe it is by no means an impossible material where it could be suitably employed.

With regard to the latter suggestion, a mere change of style would not of itself produce better buildings, for there is no such thing as an easy style to design in, and never will be.

But although the picture of what I may call the ruck of modern Gothic is so depressing, there are happily many bright exceptions, and I consider that the works of the late Mr. G. F. Bodley, G. Gilbert Scott, jun., Thomas Garner, and Sedding, not to mention others, fully justify as possible and reasonable the use of Gothic work in the present day. These exceptions show that when men thoroughly study and understand their work modern Gothic may be produced which will hold its own with, or even rival, ancient examples, and I consider that they more than justify the retention and use of Gothic for modern requirements.

One often hears it said that, even admitting the Gothic styles are suitable for ecclesiastical work, they cannot be used successfully in public buildings or domestic work; but so far as the latter is concerned it may be fairly answered that much of the most successful modern domestic work has been designed in the late Gothic manner, and the more closely the spirit and feeling of the old models have been followed, the more successful has been the result. Can it be doubted that this is largely due to the fact that the country is rich in fine old examples of late Gothic and Tudor houses of all sizes and degrees of richness, and that men study them?

Regarding public buildings the case is somewhat different, because during the Middle Ages our towns were mostly small, and any buildings of the civic character they possessed, or that still remain, are of a very simple nature. The case is, however, widely different on the Continent, where in the Low Countries and the Hanse towns of Germany, and above all in many old Italian cities, may be seen and studied civic buildings of great size and often magnificence, which clearly show what splendid results can be achieved in the Gothic styles in this class of building.

I will make a few practical remarks here on what I feel should be the general guiding principle in the erection of our smaller and simpler ecclesiastical buildings.

There is no doubt that most people care little, and know less, about architecture, and are principally influenced in their appreciation or otherwise of a building by its size and cost. On the other hand, there are many who are thoroughly and intelligently interested in the matter to whom a good building is a real pleasure, and I am sure that as architecture becomes better, architecture will be better understood and appreciated. The church of either an ancient parish or a new district should be, and generally is, an important centre of influence and interest, and it is important that however simple and homely such a building may be it should be the best that is possible.

In the case of our old churches this is almost always so, but they have the additional advantages of historic association and gradual development which a new building must lack. I do not advocate the mere reproduction of ancient examples, as obviously the requirements of to-day are not exactly what they were in the past, and a building should express in its design the time and purpose for which it was erected.

Primarily, then, the careful working out of the plan is an essential of successful building, and this must always be considered in connection with the site to be built upon. It is very seldom that a church planned for one place will come in well for another, each case requiring special consideration. As our modern churches are required above all things for a large congregation, it is important in planning the building to obtain as open and spacious an interior as circumstances will permit. It is therefore, for instance, much better in a simple building to divide your nave and aisles (which is, by the way, generally also the most economical type) by a few wide and lofty arches, carried on fair-sized piers, sacrificing the clerestory altogether, and getting the centre and aisles as much of one height as is possible.

It is true this is a departure from the general run of old English churches, where the bays dividing the nave from the aisles are generally comparatively narrow; but remember that in the old churches it was the central nave that was used principally for the congregation, the aisles being largely occupied by chantry chapels; in fact, this was often the reason of their addition to an originally aisleless building. There are not wanting, however, old churches in the country of the type I describe, and they are very common, generally on a large scale, in Northern Germany, where frequently the nave and aisles together are practically as broad as they are long.

Of course, where funds are sufficient, a finely designed clerestory is a grand feature to the central aisle of a building.

It is also more reasonable as a general rule in a modern church to omit the chancel arch and to run the chancel through at the same roof-level as the nave. This arrangement is common enough in many of the later large churches of the eastern counties, and is also to be met with in a good many of the fifteenth-century churches of the West Riding and Lancashire.

Another type very suitable for our modern purposes, where economy is of importance, is that of two or three aisles of about equal width, such as is frequently met with in Devonshire and Cornwall.

Types such as these would be infinitely preferable to that ordinarily adopted and need not be more costly. There are indeed many ways in which the problem can be solved, though the success or otherwise of doing so depends, of course, on the skill and knowledge of the designer.

I mentioned that an apsidal termination to the chancel is less popular now than it was a few years ago, and there is no doubt that the square-ended chancel is as a general rule the right thing for us. It is the traditional plan in England, which tradition undoubtedly goes very far back. I have heard it said, though I would not express any opinion on the accuracy of the statement, that it arose in early times from the precedent set by St. Joseph of Arimathea, when he erected a rectangular church of "daub and wattle" at

Digitized by Google

Glastonbury. However this may be, it is a fact that the square east end has always been the favourite plan in the British Isles, and has invariably reasserted itself after the introduction of the apsidal form from the Continent, as, for instance, by St. Augustine's missionaries from Rome, and again after the Norman Conquest. The few instances of apsidal terminations in English parish churches, such as St. Michael's, Coventry, are not strikingly successful, and one reason is that an apse to be satisfactory must have a vaulted roof, for a flat perpendicular wooden ceiling does not fit nicely to a canted or circular end, and the high-pitched roof of barrel form is still worse, because unless the walls are of great height, as one sees sometimes in France, the great mass of roof at the east end above the windows gives a very heavy and dull effect. Where the height to the wall plate is moderate, as it must be in any economical type of church, the square end to the chancel allows of the east windows being taken well up above the wall plate and gives the apparent height required for a satisfactory effect.

The French apse with its tall proportions and vaulted roof and circlet of chapels is probably the most beautiful finish to a Gothic church that could be conceived, of which we have an unrivalled example in Westminster Abbey.

I have heard it asserted that the actual merit of the design of the interior of a church is not of such very great importance; that it is possible to make it beautiful by good decoration and fittings. Statements of this kind may sound plausible, but are entirely misleading.

If a building is badly designed, I mean in the architectural sense, no amount of decoration or other adornments will make a good building of it. I could *name* instances within my own knowledge where much money has been spent in the attempt to get a satisfactory effect in this way, but the success has been invariably very limited.

On the other hand, a good building will repay proper furnishing, and its good qualities will even assert themselves in spite of, as is too often the case, mean and unsuitable furniture.

I do not wish to be misunderstood on this subject of the furnishing and appointments of the interior of the church. The matter of their design and workmanship is of the highest importance, and it is often most difficult to get people to understand this. The illustrated catalogues of the church furnishing shops contain almost everything in the way of ecclesiastical furniture and fittings, from the smallest to the most important, and all, I may say without exception, of the vilest description both in design and execution. There may sometimes be the excuse that their things are cheap, that they are the best that can be got for the money, and so forth; but this is really not so, for it is quite possible to get good simply designed things made at a moderate cost.

A few concluding remarks as to the type of English Gothic most suitable for modern work.

I do not consider it is advisable to set up the claim for the sole employment of either the earlier or later Gothic styles. It is not of great importance whether you prefer to design in Early English, Flowing, Decorated, or Perpendicular, so long as the design itself is good. But a good design in any of the Gothic styles can only be achieved by careful first-hand study of old examples, firstly in this country, but not neglecting the magnificent Gothic styles abroad. In the later styles the object was chiefly to obtain as much window space as possible for the display of the splendid stained glass of the period.

Now modern stained glass is not as a rule of such quality as to justify the provision of very large windows; and the risk of having your interior disfigured by, say, a large east window filled with some atrocious production from the studio of the cheap and popular glass painter, British or foreign, is well worth keeping in mind. Less risk of a disaster of this kind is run with the smaller windows of the earlier style, but in this case the lancets must have good broad splays, or be set in deep recesses, as nothing can be worse than windows of the early type put in thin walls.

Much more might be said on the choice of styles and other matters, but there is no time for it now. What I wish to emphasise above all things is the importance of a thorough and constant study of old work by architects if they wish to produce good work either in large or small things.

I once heard it stated by an architect in considerable practice that it was unnecessary now to spend time on the study of old work, because there are so many illustrated books of buildings in all styles that architects can easily give their clients anything they require in this way. Doubtless this has been the general practice with many, and is, I believe, responsible for much of the lifeless work we see and deplore.

VICTORIA AND ALBERT MUSEUM ACQUISITIONS.

A LIST is here given of the more important objects acquired for the collections by purchase in 1907 and 1908. In 1907: a collection of English furniture principally of the eighteenth century, Swiss and German stained and painted glass of the sixteenth and seventeenth centuries, and an incense burner with two vases of Chinese cloisonné enamel of the eighteenth century, formerly belonging to the Massey-Mainwaring estate; the panelling and fittings of two rooms of the first half of the seventeenth century from a house known as the Casa Mattei at Osogna, Switzerland; two carved wood groups representing St. Anne with the Virgin and Child, and the marriage of the Virgin, Flemish and German (Lower Rhenish or Westphalian) work, about 1500; an oak cabinet, Dutch carving of the first half of the seventeenth century; a collection of Hispano-Moresque lustred pottery dating from the fifteenth to seventeenth century; a collection of Persian lustred ware and tiles of the thirteenth century; a small collection of Græco-Buddhist sculptures of the third and fourth centuries, carved in talcose-schist, found in the Swat district, North Panjab Frontier; two carved stone chimney-pieces, English, about 1600; an English clock-watch of the late seventeenth century in silver case, pierced and engraved (the back inscribed with the dates of church festivals, saints' days, and law terms), with striking and alarm mechanism and an outer case of shagreen and brass, signed "Eduardus East Londini"; a collection of eighteen bowls and salvers of hammered brass, German, sixteenth-century work; a German badge of a guild of St. George of silver-gilt set with coral and malachite, in the centre an equestrian figure of the saint on a background of translucent enamel on silver, the back engraved with the inscription SANKTVS GEORGIVS ORA PRO NOBIS A.D. MDXXVIII; a large brass chandelier from the Nieuwekerk, Amsterdam, Dutch, early eighteenth century; a jewel case mounted in gilt metal, cast and engraved, Augsburg, sixteenth century; a double cup, silver-gilt, made by Jeronymus Behaim, Nuremberg, about 1600; a cup "Monatsbecher," silver-gilt, made by Hanss Beutmüller, Nuremberg, late sixteenth century; a bronze candlestick, inlaid with silver, Saracenic work of the fourteenth century; a brass tray and candlestick, inlaid with silver, Saracenic, thirteenth and fourteenth centuries; a chasuble of Florentine crimson velvet brocade of the middle of the fifteenth century, with English embroidered orphreys bearing the arms of Henry de Beauchamp, Duke of Warwick (d. 1445) after his marriage with Lady Cecily Nevill in 1434; a collection of woven fabrics, chiefly Italian and Spanish, fifteenth and sixteenth centuries; a collection of Persian brocades, sixteenth and seventeenth centuries; a Persian brocaded dalmatic of the late seventeenth or early eighteenth century; a miniature dated 1781 by John Smart, of Sir Philip Francis, the supposed author of the letters of "Junius"; a miniature dated 1719 by Christian Richter, of Dr. John Radcliffe, of Oxford, physician to Queen Anne.

In 1908: Florentine velvet chasuble with embroidered orphreys, fifteenth century; panelling and ceiling of a room with doorway dated 1493, from a house at Uerikon, near Zurich; seven small groups of oak, representing scenes from the history of the True Cross, Flemish, early sixteenth century; figure of a bishop in carved limewood, German (Franconian), late fifteenth or early sixteenth century; three panels of stained glass, Flemish, first half of sixteenth century; panel of stained glass with the arms of Elizabeth Plantagenet, duchess of Suffolk, English, about 1500; six watches in elaborately decorated cases, English and French, seventeenth century.

The complete lists of the gifts and bequests for the years 1907 and 1908 are given in the reports of the Museum. Notable among them in 1907 are:—a collection of Chinese porcelain of the period and style of the Emperor Yung Chêng (1723-1735), given by Mrs. Gulland; a collection of blue and white Chinese porcelain chiefly of the period of K'ang Hsi (1662-1722), given by A. Burman, Esq.; a pair of stirrup-irons of enamelled brass, English seventeenth-century work, given by J. H. Fitzhenry, Esq.; a silver-gilt chalice, with enamelled bosses, Dutch (Zwolle?), dated 1524, given by J. B. Carrington, Esq.; a collection of twenty-seven Japanese netsukés, principally in ivory and wood, of the eighteenth and nineteenth centuries, bequeathed by R. T. Pritchett, Esq.; a grand piano made at Vienna, and an upright piano, harp-shaped, made at Amsterdam, early nineteenth century, given by Sir W. Q. Orchardson, R.A.; objects of ancient Egyptian workmanship have been received

Digitized by Google

from the Egypt Exploration Fund, and the British School of Archæology in Egypt.

Among the principal gifts in 1908 may be mentioned:—Portion of a woollen pile carpet woven with the royal arms of England and the initials E R, English, dated 1600, given by Major Harlowe Turner; oak dole-cupboard, English, about 1500, given by F. G. Hilton Price, Esq., Dir.S.A., through the National Art Collections Fund; pair of carved oak doors and walnut coffer, French, late fifteenth century, given by J. H. Fitzhenry, Esq.; Chinese cast bronze bell, Chou dynasty (1122-225 B.C.), given by the executor (A. Burman, Esq.) of the late Charles Meredith Dyce, Esq.; collection of 112 Japanese swords, daggers, &c., given by R. A. P. Davison, Esq. Objects of ancient Egyptian art have been presented by the British School of Archæology in Egypt.

There have been various gifts to the Art Library.

Herr Langhans, who has on former occasions given large numbers of interesting photographs of art objects in Bohemia to the Art Library, presented, in 1907, three sets of photographs of objects in the Archiepiscopal Palace at Prague; while a set of 161 views (principally of Byzantine churches) in Cilicia and Lycaonia was presented by Miss Gertrude Lowthian Bell. Additions were made by Mr. C. E. Keyser to the collection of photographs of sculptured tympana and Norman doorways in England which he has from time to time presented to the library.

Another notable gift was the "Inventaire de l'argenterie conservée dans les . . . palais impériaux," St. Petersburg, 1907, presented through the Imperial Russian Embassy.

The Phené Spiers collection of drawings of architecture received 493 additions during the year 1907, and on December 31 of that year numbered 652 measured drawings, plans, &c. Further additions to this collection have since been made. An important gift by Mr. C. Mallord W. Turner consisted of ten impressions from unpublished plates of J. M. W. Turner's "Liber Studiorum," and the collection of etchings was increased by examples of their own work presented by the following artists:—Mr. Frank Short, A.R.A. (one), Mr. W. W. Burgess (two), Mr. J. R. G. Exley (three) and Mr. Malcolm Osborne (three).

THE CONCRETE INSTITUTE.

AT the fourth general meeting, held on March 18 at the Royal United Service Institution, Whitehall, a paper on "Concrete in Arched Bridge Construction" was read by Mr. E. P. Wells, J.P., hon. treasurer, Concrete Institute. He said the materials used in the construction of arches in this country had been confined in the past to stone, bricks, iron and steel, and it was seldom that any other materials were used, unless it were for arches of very small spans, many engineers and architects, for reasons of extreme caution and safety, being indisposed to use concrete. But the use of Portland cement concrete was more satisfactory, not only as regards strength, but also as to first cost, an item which at the present day had in many instances to be seriously considered.

One of the principal reasons why concrete had not been more often used in this country was the fact that very few engineers had ever seriously experimented with this material; they had only considered it good enough for retaining walls and foundations, and some engineers did not place much faith in it even for the latter work, and where it was used it was very often made abnormally strong for fear of accidents happening.

The lecturer knew of cases where the loads on the foundations did not exceed 2 to 2½ tons per square foot, and the concrete was made in the proportion of four to one; whereas this material would carry with perfect safety 100 tons per square foot two months after being made, assuming, of course, that all the materials were good and clean and the Portland cement was of the ordinary best quality made and not adulterated.

Advantages of Concrete.

There was a homogeneity about concrete, when properly made, that was not obtained where bricks or stone were used; and those who had had to pull down structures built of either stone, brick or concrete, the lecturer thought, would agree with him that concrete was not the material he would prefer. His experience was that good concrete well rammed was a most difficult material to break up when made en masse; and if by any possible chance iron had been used in combination, then it required dynamite or some other explosive to shatter it.

The lecturer explained that he intended to confine himself principally to pivoted arches, which were theoretically and practically the only form of plain concrete arches that ought to be constructed, and he would show how pivoting at both the springings and centres came to be adopted.

Curve of Equilibrium.

Previous to the adoption of the pivot at both the springing and centre of the arch it was felt by German engineers that some method should be adopted whereby the curve of equilibrium could be absolutely confined within the centre third. It was well known that in a stone arch it was almost impossible to ascertain where the curve of equilibrium would run, as everything depended on perfect construction, especially in the grouting of the joints, &c.; any defects in grouting up would cause an alteration in the curve of equilibrium and in all probability might endanger the safety of the structure. It was this difficulty in bedding stones of large area that had compelled engineers to put such a large amount of material in stone arches so as to be on the safe side.

Settlement of Stone Arches.

To show what effect settlement had on a stone arch the lecturer called attention to the shore span of Waterloo Bridge on the Surrey side, where it was found upon examination that the abutment moved about half an inch, the result being that the joints opened at the keystone and the whole thrust of the arch passed through a few inches of the extrados; this had caused the voussoirs to spall, and a further movement of half an inch might cause serious mischief to this national monument.

Some years ago a bridge was constructed in Germany where mortar joints were dispensed with, and in place thereof sheet lead was used, each piece of lead being made the area of the centre third and fixed on the centre third of the stone. This overcame the difficulty to some extent, as the curve of pressure was compelled to pass through the centre third; but this method of construction was expensive, as the arch stones had to be very carefully dressed to an even thickness, so that all joints were linable throughout, or the thrust in the arch would have been very unevenly distributed. The lecturer believed only one bridge on this principle was constructed; but another bridge was built (viz. at Kirchheim) where only lead was used at the springing and centre, covering about one-sixth of the cross-sectional area of the arch. It was left to the late President von Liebbrand, the chief engineer to the State of Würtemberg, to adopt the method of pivoting in its application to the concrete and stone arches; and the adoption of this principle had enabled the State of Würtemberg to erect concrete bridges of large spans all over the country, where the use of stone would have been undesirable on account of cost.

Pivoted Bridges.

The first pivoted concrete bridge from the design of the late President von Liebbrand that was constructed in Würtemberg was a large one, viz. 164-foot span, and was the pattern in respect to facilitating erection, reducing the dimensions in the arch, and the use for the first time of the pivot at the springings and centre, which since then had been invariably adopted for concrete arch construction on the Continent, excepting those cases where the concrete had been reinforced with steel and the arches made with fixed springings and practically continuous from abutment to abutment.

Construction of Concrete Bridges.

The lecturer then proceeded to describe the construction of a concrete bridge having a span of 150 feet with a rise of 19 feet; this bridge, the dimensions of which he gave, was strong enough to carry the heaviest possible vehicular traffic as also the heaviest railway traffic, and to carry a load of over 3 cwt. per foot super on one half with the other half unloaded, and all this without the use of steel in its construction; but if steel were used then the loads could be very materially increased.

The principal reason why these concrete bridges were so safe under unequal loading was due almost entirely to the pivots at the springings and centre, which compelled the curve of pressures to pass through the same, the only sensible variation in the curve being at the haunches; even the loading given would not in any case alter the curve so that it passed above or below the middle third. Such being the case, it would be observed that no part of the arch could be in tension; but should such a thing happen theoretically, the spandril walls, by their great rigidity, would prevent any distortion of the arch; and, if the spandril walls and

Digitized by Google

tables were reinforced, it would be possible to put a tension of 10 to 15 tons in either the extrados or intrados without the structure collapsing or changing its form.

Another advantage that a concrete arch possessed over a brick or stone arch was its homogeneity, there being an absolute lack of joints, which were an element of weakness, as was the mortar in the joints; e.g. in the case of a granite arch, one-twentieth the crushing strength of the stone itself if made of lime and one-quarter the strength if cement grout were used; then why use a material that was stronger than the weakest part?

The Arch.

In designing a concrete arch it would be found necessary to start on the assumption that the thinnest part of the arch—viz. at the centre—is approximately one-fiftieth of the span; this you must increase at the springing by about 7 per cent. and at the haunches by about 27½ per cent., to allow at this point for varying loads tending to make the curve of pressures rise or fall either below or above the neutral axis, and so to always keep the said curves within the middle third.

Having then apportioned the sizes of the spandril walls, or spandril pillars, to the loads that the bridge is intended to carry, also the intermediate tables and tables to carry the vehicular and foot traffic, proceed to ascertain the weight of the structure and find the curve of equilibrium for the dead load only; having ascertained that, make it the neutral axis of the arch, and alter the shape of the extrados and intrados by compounding the curves so as to make both equi-distant from the neutral axis. The normal condition of a concrete bridge was its dead load and the greatest stresses were set up by the dead load; so the lecturer considered that, unless extraordinary loads were to be passed over the bridge, it was not necessary to take into account the live load, especially if it were only ordinary or vehicular traffic. If the curves for equally distributed loads and also for one-half of the arch loaded were worked out it would be found that the curve of equilibrium at the haunches did not vary more than 3 inches either above or below the neutral axis; in the case of a heavy rolling load, it was only when the load was at the centre of the span or a few feet on either side of it that the increased stresses at that point in the arch could be accurately calculated; because nearly the whole width of the arch, from the point under the load to the springing, took up the stresses induced, and the same were reduced to a minimum by the enormous area of arch that they were spread over; the reason why concrete arches were so strong was that the stresses induced by the weights were so well distributed; otherwise there would no doubt be distortion of the arch and great deflection at the centre, whereas in no case where exhaustive tests had been carried out had this been proved.

Under these circumstances it was perfectly permissible to reduce the thickness of the arch until the stresses amount to 36 tons per square foot; but it would then be required to ascertain the positions of the curves of equilibrium for dead load, equally distributed live load and also for one-half of the arch loaded, and likewise for the maximum rolling load placed in the centre of the span; the neutral axis could then be made the mean of all the curves.

The effect of this would be that at the haunches, for dead load only, the compression at the intrados would be slightly increased and correspondingly reduced at the extrados; the curve of the intrados would not require so much compounding, but would be more segmental in form, unless they were placing excessive dead loads on the haunches, when the curves of pressure would rise, and so enable the curves of the intrados to be compounded and the appearance of the arch very materially improved.

If it were possible in concrete arch construction to make the arch so that the dead load were equally distributed, then the curve of equilibrium would be a parabola; but the appearance of the arch would suffer, though theoretically correct.

Spandril Walls.

In all cases the spandril walls, and also the concrete filling over the arch beyond the spandril walls at the centre, should be bonded to the arch by means of stone figs or old iron rods, in the shape of bolts, &c., as by this means any separation taking place between the extrados of the arch and the spandril walls could be absolutely prevented and the cementitious nature of the concrete had not to be depended upon, which was not always desirable unless very great care be taken in roughing the concrete and making the same absolutely clean.

Centrings.

The centres needed for the erection of a concrete arch were similar in every way to those required for a stone or brick arch, with this exception, that less strength was wanted, owing to the fact that a concrete arch weighed less.

Where it was required to construct the whole arch of concrete and make imitation stone voussoirs, special shuttering must be made. This could be moulded to any desired form, but great care must be exercised in fixing the shuttering and in well strutting the same, so that in making the concrete voussoirs the ramming did not cause the shuttering to bulge. The shutters for concrete voussoirs could be formed out of 2-inch to 2½-inch wood strengthened with rails, &c., the surface exposed to the concrete being machine-wrought; but it was not essential that they should be of an even thickness, as a light variation would, when the voussoir was constructed, act as a key. On the top of the laggings the thickness that the concrete voussoirs were required to be formed should be marked off, the shuttering fixed, the faces in all cases being radial to the curve and care taken to thoroughly well strut the shuttering, so as to prevent undue distortion in consequence of the weight of concrete. After this was done the surface of the laggings should be covered with about 1 inch of one part sand to one part Portland cement (made dry), and then as rapidly as possible concreting commenced; the quicker the concrete was put in and well rammed, the stronger and better it would be. When once a concrete voussoir was started it must be finished without a break, and sufficient men should be employed so that from start to finish not more than two hours would elapse. When about three-fourths of the voussoir had been finished, the stone figs or iron rods, &c., should be built in for bonding the spandril walls to the extrados of the arch.

After the concrete was set the surface should be covered over with wet sacks and kept well wetted during the whole time that it is exposed.

Order of Fixing Voussoirs.

It was advisable when forming the concrete voussoirs to always place the first voussoir between the points of support of the centres, not over the supports; thus, if any deflection was caused by the weight, it was put into the beam before the remaining voussoirs were made.

In closing in with the voussoirs Nos. 3, 5, 7, 9 and 11 care should be taken that the faces of the existing concrete voussoirs were thoroughly clean and well roughened; and, as the concrete was brought up, neat cement grout or one to one cement mortar put on the faces of the existing concrete, so that a perfect bond was obtained between the new and the old. When ramming the concrete care should be taken that the existing faces of the voussoirs were not in any way damaged. To prevent this it was advisable to use special hardwood rammers. Lest by any chance the faces of the voussoirs previously put in should be honeycombed, some one to one mortar should be used to fill up all interstices previous to the concrete being filled in.

After the completion of the voussoirs Nos. 2 to 12 it became necessary to adjust the granite blocks.

Pivots.

The pivots should be made of the best annealed cast steel, carefully machined all over to uniform thicknesses; the rolling curves should be machined and finished to a dead smooth surface, the pivots being forced into the bearing plates by hydraulic pressure; if it be found that the faces of the pivots were not parallel with the bedplate, then the back of the same must be re-machined.

The granite bearing stones must be recessed for about 1 to 1½ inch, and the bearing surface bush axed or (which is preferable) sand rubbed, as it was advisable that there should be no inequalities in the stone to prevent a perfect bearing being obtained.

The stones should be made in about 2-foot 6-inch lengths, and the pivots should be about 1 inch less in length. The joints for these stones should be about ¾ inch, and were not to be made until after the final concrete voussoirs were filled in.

Before fixing the pivots in the stones, sheet lead, about ⅛ inch thick, should be put in the recess in the stones, and the pivots laid in and well hammered with a heavy wooden mall, after which the stones should be fixed in position, and very great care exercised in gauging the distance between the rails so as to ascertain whether the bearing of the two rails is true; any inequality in the position of the stones could be obviated by packings laid on top of the laggings.

Use of Screwjacks for Fixing Pivots.

After all the stones were in their correct positions it would be necessary to obtain four screwjacks so as to force the pivots as close together as possible and at the same time put a certain amount of compression on the lead seatings; when this was done, 2-inch square iron or steel bars should be forced between the back of the stones and the concrete voussoirs Nos. 2 and 12, so as to prevent any movement when the screwjacks are taken away.

In Germany they use ¾-inch bolts top and bottom, placed in the joints of the stones; but by this means very little pressure was exerted, and the bolts had to be left in until concreting was finished and afterwards cut out, which was a most difficult and very expensive method of procedure; it was, in the lecturer's opinion, one of the principal reasons why there was so much deflection in the arch when the centres were struck, owing to the fact that so little pressure was put on the seatings previous to concreting in.

There was no doubt that concreting exerts a large amount of pressure on the granite blocks, especially when the concrete was made fairly dry and heavy ramming was employed; but the pressure was light as compared to that exerted by four powerful screwjacks.

After all the stones were placed in position the concrete voussoirs Nos. 1 and 13 should be filled in; the voussoirs in the centre ought to be filled in simultaneously.

Striking Centres.

It was not necessary that the whole of the outer spandril walls should be constructed before striking the centres; but, if there were no urgent reason why the centring should be removed, it was better to let the same remain, as it acted as a staging to enable the masons to set the stones on the spandril faces. But within three weeks after the completion of the final concrete voussoirs it was advisable to ease the centres a trifle, so as to allow a moderate amount of pressure to be exerted on the pivots; where screwjacks were used this could be easily done without in any way setting up vibration in the arch such as takes place when folding wedges are used.

Roadway.

After the centres were finally struck the concrete over the arch, forming the roadway and footway, might be filled in, care being taken to make an expansion joint over the pivots in the centre of the span and also at the springing pivots. In this country a joint ⅛ inch was sufficient at the centre, and the same could be made with soft felt; but at the springings, if the concrete be put in in cold weather, fully ½ inch must be allowed. In forming the roadway, whether of wood paving, granite pitching, asphalte or macadam, the expansion joint might be ignored, though one must be put in on the footways, especially if the same were made of York paving or concrete.

In order to allow the arch to expand, the outer spandril faces must not be bonded to the abutments or piers, but be recessed into the same, so as to allow perfect freedom of action; this also applied to the parapet and cornice, because, if securely fixed, an accident was bound to happen in winter if the bridge were completed in summer, and vice versâ.

The lecturer then described some tests on a model bridge of 150-foot span to a scale of ½ inch to the foot, and then described a few of the principal concrete bridges that have been erected abroad, commencing with the Coulouvrenière Bridge across the Rhone at Geneva. These were illustrated by means of lantern slides. Finally, the lecturer made extended remarks on the making of concrete and the proper proportions that ought to be used for different kinds of work. The results of many tests and experiments on concrete carried out by the lecturer formed addenda to the paper.

The Conference on roads and motors, which is being called by the County Councils Association, will be held from April 29 to May 1, at the Institution of Civil Engineers, the Institution of Mechanical Engineers and the Surveyors' Institution, sectional gatherings assembling on the first two days, and a full meeting, at which alone resolutions will be put, on the last day. Lord Belper is to be president of the conference, and Colonel Dixon (chairman of the Cheshire County Council) chairman of the committee. Between forty and fifty papers will be submitted and most of the county councils, many of the municipalities and the principal societies interested in road matters have already appointed representatives.

GENERAL.

Sir G. Frampton, R.A., is to be invited to execute a statue of the late Marquis of Linlithgow, which is to be erected as a memorial in Edinburgh.

Mr. Solomon J. Solomon, R.A., has been entrusted with a commission to paint a portrait of Mr. William Longair, ex-Lord Provost of Dundee.

Mr. Mervyn Macartney, F.S.A., F.R.I.B.A., has been appointed by the President of the F.R.I.B.A. to act as assessor to the Berkshire County Council in their proposed competition for county buildings at Reading. Mr. Macartney will prepare the information for the competition advertisement and will report upon the plans submitted.

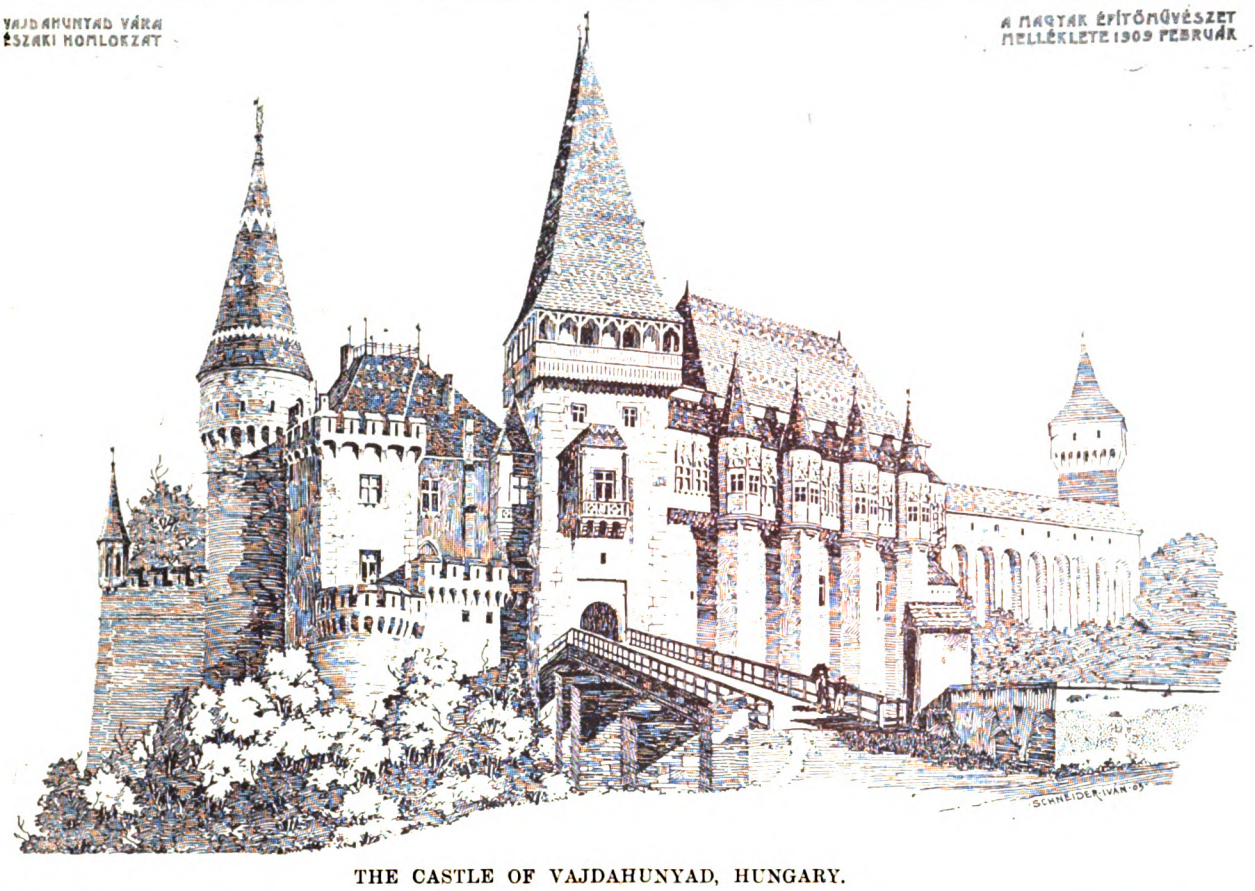
The Council of Liverpool University on Tuesday appointed Mr. Stanley D. Adshead, F.R.I.B.A., as associate professor of civic design in the University for a period of three years. This appointment has been rendered possible by the generosity of Mr. W. H. Lever, M.P., and is the first appointment of its kind made at an English university. It is hoped to found in Liverpool a strong department of civic design and landscape architecture in the School of Architecture. Mr. Adshead has had a distinguished professional career and is still a young man, having been born in 1868. It is believed that the new professor has not only the technical knowledge but the initiative, independence of judgment and power to conceive original schemes necessary for the teaching of this subject. Mr. Adshead has given proof that he possesses the ability to express his ideas clearly, more especially in the pictorial form.

Messrs. J. M. Bottomley, Son & Wellburn, architects, of Leeds, have been awarded first place in a competition for a municipal high school for girls at Doncaster. The cost will be 13,000*l.* Mr. E. F. Robson acted as assessor.

Grimsby Town Council has decided to invite competitive designs for the enlargement of the town hall at an estimated cost of 30,000*l.* The first prize will be 250*l.*, the second 150*l.*, and the third 75*l.* Should any of the winning designs be carried into effect the prize will merge into the successful architect's fees.

As a Protest against the threatened demolition of Bath Street, Bath, the agitation for its preservation still continues. A public meeting has been convened, at which the Rector of Bath will preside, and the speakers will include Mr. MacColl, keeper of the National Gallery of British Art, and Professor Beresford Pite.

Whalley Church, Lancashire, is to be renovated and altered at a cost of about 3,000*l.* The present church was erected in 1283. Whalley's legal parish is the largest in the county, covering in all sixty-six parishes.



An Anonymous Donor has offered the Plymouth education committee a copy of the thirty-seven volumes already issued of the library edition of the works of John Ruskin. The conditions attached to the gift were that the volumes should be placed in the school of art for study or reference there by teachers and students of that school, and that they should not be taken out of the school by any person except with the express permission of the head master. The committee decided to accept the gift with thanks.

An International Exhibition of railways and land transport is to be held at Buenos Ayres from May to November 1910. The first section includes projects, drawings and photographs of stations, general plans, passenger and freight stations, passenger buildings, platforms, tunnels and viaducts for communication between platforms. Anyone wishing to take part in the exhibition should apply to the district committee local board or delegates. Applications should be submitted not later than June 30, 1909, and the exhibitor binds himself *ipso facto* to abide by all rules of the executive committee.

Lady Margaret Hall, Oxford, is to be enlarged. Plans have been drawn up by Mr. Reginald Blomfield, A.R.A., for a building which will contain a dining hall, kitchen, library, principal's and students' rooms. The cost of the whole, with the addition of a chapel large enough for the increased numbers, will be between 17,000*l.* and 18,000*l.*—7,000*l.* for the dining hall and library block, 7,000*l.* for the new students' wing, and not less than 3,000*l.* for the chapel. A commencement of the work is to be made at once.

Dunbar Town Council have decided to augment their existing water supply by putting down storage tanks sufficient to provide about 20,000 gallons per day for thirty days, and negotiations are now in progress for the acquisition of the necessary land on which to erect the tanks.

THE CASTLE OF VAJDAHUNYAD, HUNGARY.

THE WEEK.

Few of us realise, when we take our "Hunyadi Janos" in the morning what the name means to a Hungarian. John Hunyadi was one of the greatest warriors and statesmen of Hungary, the world-famed defender of Christian Europe against the Osmanlis, the father of the splendid King Mathias the Just. Belonging to what was in his day a Magyar knightly family of new creation, he by merit as much as by favour rose rapidly in rank, married the daughter of a Hungarian lord, distinguished himself as a leader of the king's troops against the Turks, and, as Banus of Szörény, himself rose to the rank of lordship. Finally, after the early death of King Albert, he was elected, by the Diet, governor of Hungary during the time of the infancy of King Laszlo V. As a fitting residence for his exalted rank he built the castle of Vajdahunyad, of which we give a view and which is fully described by Professor Virgil Nagy in the "Magyar Epitömüvészet," together with numerous excellent illustrations. The castle was finished in the year 1452, but must not be taken as strictly representative of Magyar architecture at that date, for Hunyadi accompanied the Emperor Sigismond on his five years' Western journey to Switzerland, Germany, France, the Netherlands and England, and, being a man of refined taste, imbibed some of the feeling of the foreign architecture, especially of France, that he had seen on his travels. The castle was much damaged by fire in 1854, and practically all the present roofs are part of the restoration carried out by Professor Steindl. The Hungarian language is no doubt incomprehensible to most of our readers, but Professor Nagy has included with his descriptive article a page in English epitomising the main points of the history of the castle of Vajdahunyad and its owner, Hunyadi Janos.

Mr. M. H. Spielmann, in his lecture last Monday at the Royal Institute of British Architects on "British Sculpture of To-day," very ably put the case for our modern British sculptors. He not only pointed out the vast improvement that has taken place in our sculpture during the last thirty years which he was, as we all know, fully justified in doing, but upheld the doctrine that sculpture is and should be idealised form without colour. This doctrine we hold to be heretical as regards the exclusion of colour, and due only to the incomplete revolt of our sculptors against the paralysing thraldom of the ideas and conventions of the eighteenth and nineteenth century schools of sculpture. Our best men to-day have broken away from this thraldom as regards form and subject, but we cannot help thinking they are still slaves to monotint. In all great ages of art in the past, Greek, Mediæval and Renaissance, coloured sculpture was in vogue; in Nature there is no such thing as monotint, and our sculptors, in adhering to monotint, are maintaining an artificial convention that has no warrant either in Nature or in the best periods of art. There is no need for the colour to be imitative or realistic, but we believe colour must be allied with form, both idealised, before sculptors can expect the Philistine to properly appreciate their art. The art that requires explanation and education before comprehension is, like the work of the sculptor in the early Victorian era, artificial and dead. There is in the Philistine, after all, a good deal of Nature-instinct, and his taste is not always to be despised because he does not regulate it by the rules of academic teaching. Architects know very well how the colour of material modifies the effect of form in their mouldings, and in asking our sculptors to add colour to their form we are aware that we are setting them a stiff row to hoe, and that very considerable modifications of their technique will have to be adopted, but the strides that have been made are sufficient to lead us to believe that the added difficulty will only still further enhance the excellence of modern sculpture.

As a field for archæological research, Egypt proper is practically exhausted, but a rich field appears to be still open for explorers in the Sudan, where the Ethiopian kingdom of Meroë has left many monuments of its greatness, some still above ground, but many more probably still requiring excavation. The only trouble is that for the want of 500*l.* a year unauthorised pilferers are clearing away what should be unearthed by capable investigators, and that no adequate accommodation at present exists for the finds that the latter are obtaining.

THE DEVELOPMENT OF MEDIÆVAL ARCHITECTURE.

FROM the earliest times until the upheaval of the Renaissance movement, the history of architectural development was so unbroken in its continuity, at least in Europe, that the fixing of any particular date at which to commence an account of Mediæval architecture is purely arbitrary, and it is only the sharp contrast between the comparative slackness of building in Christendom during the tenth century, which prevailed whilst the minds of Churchmen were oppressed with the foreboding that the world would end with the year 1000 A.D., and the remarkable activity that occurred during the eleventh century, that affords a reasonable excuse for taking the beginning of that century as the starting-point for the study of Mediæval architecture, as does Professor Simpson in his second volume of the "History of Architectural Development." *

The history of Mediæval architecture is the history of building with the arch. In Greek architecture the column with its lintel reigned supreme; in Roman times there was a dual monarchy of column and arch; in the latter days of the Roman empire, the days of Diocletian and Zenobia, there arose a contest between the joint rulers, a contest in which the Romanesque period saw the victory of the arch, which henceforth during the Mediæval era reigned alone and rendered possible the construction of great and beautiful buildings with small stones. The evolution of the arch of small stones is admirably elucidated by Professor Simpson, who rightly points out that it is not the shape of the arch, circular or pointed, but its construction that determines whether the architecture that employs it is Gothic or Classic.

Small stone arches lead naturally to groin-rib vaulting, which, says our author, is "the most characteristic trait of Mediæval architecture," and the development of which, both constructive and æsthetic, is clearly and fully explained. What a pity it is that, when we are writing in English about vaulting, we cannot all agree on a consistent and uniform nomenclature. If we borrow "tierceron" and "lierne" from the French, why not also "formeret" and "croisée d'ogive"? But surely the resources of our native tongue are sufficient. The tierceron is intermediate between the wall-rib and diagonal-rib, and the title of intermediate-rib sufficiently denotes its position in the vaulting scheme. The lierne is wholly on the soffite of the vault, and, if we agree to call it soffite-rib, is more readily comprehensible by the student, and, after all, books on architecture are written chiefly for those who want to learn, not for those who know. In the second edition of Professor Simpson's book, which can hardly be long in appearing, we hope to see the barbarisms "four-tite" and "six-tite" amended to "four-part" and "six-part," which are quite as terse and far more expressive.

We are delighted to find that a writer on Mediæval architecture, with the authority that Professor Simpson's position carries, has emphasised, no more than is due, the high importance for a true realisation of Gothic architecture of the recognition of the part that colour played in Mediæval churches. He says, "When built they were a blaze of colour from floor to roof." It is true he limits his assertion to "the interiors of many Mediæval churches" with the care for scrupulous accuracy that is an outstanding feature of the book before us. We should go further and say that we believe that, at least in our own country and in the fifteenth century, every church in the land contained colour decoration. We do not even except our Romanesque or Norman churches, but hold that Copford, instead of being unique, is but the fortunate survivor of many contemporaneous examples. We are aware that the painting in Copford Church was restored by Mr. Bell, but it was conservatively done, with knowledge and reverence. The Professor, ever careful, says of the Romanesque workman, "the absence now of paintings in his churches does not necessarily mean that none ever existed there. Many have doubtless been destroyed." It would make a fifteenth-century builder or cleric shriek with horror to see what has been done in the nineteenth century, in ignorance of the general Mediæval use of colour—walls stripped of their plaster and rubble masonry pointed in black mortar!

It is well, therefore, that it should be universally recognised that a Mediæval church is incomplete without colour decoration.

The concentration of loads on definite points that resulted from the use of groin-rib vaulting gave the opportunity for the development of the traceried window, and the steps by which this grew from the simple lancet to the elaborate consummation of the fourteenth and fifteenth centuries is clearly traced by Professor Simpson. From the concentration of loads also followed the development of the buttress with its flying arches and pinnacles, and these go far to produce the predominance of the vertical line in the design of Mediæval buildings.

Thus all the characteristic elements of Gothic architecture which differentiate it from Classic spring from the development of arcuate construction with small stones, the typical treatment of mouldings, vaulting, tracery, and verticality in composition.

The development of church planning during the early part of the Mediæval period is best studied in the buildings of France and Germany, where there was evidently a struggle between the Eastern or Byzantine type and the Western or Basilican, as is evidenced by such examples in France as Germigny-les-Prés; S. Croix, Montmajour; S. Benigne, Dijon, and possibly Charroux; and in Germany, Aix-la-Chapelle; St. Gereon, Cologne, and Ottmarsheim. In England the Byzantine bid for supremacy is comparatively feeble, but the four so-called "Templar" churches, London, Northampton, Cambridge, and Little Maplestead, may be cited as examples, to which may be added the circular chapel in Ludlow Castle.

In the thirteenth century the typical church plan of Mediæval architecture may be said to have become settled, subsequent modifications being of minor importance, and then we have the characteristic French plan of a short and broad building with the chevet at the east end, the English long and narrow, with a square east end and prominent transepts. In Germany no one type predominated; there we find square east ends and apsidal, either with or without the encompassing chevet, long churches and short ones, with the peculiarly Teutonic hall-church plan, having its aisles of the same height as the nave. We are glad to find the authority of Professor Simpson endorsing the view that we have always held to be correct of the reason for the predominance of the square east end in English Mediæval church plans—the traditional influence of the early British Christian or Keltic type of plan, an influence that was only temporarily threatened by the reintroduction, after the cessation of the Roman domination, of the apsidal form by Augustine and his compatriots. By the way, Professor Simpson refers somewhat doubtingly to the two apses, one at the east end, the other at the west, that Augustine's church at Canterbury is believed to have possessed. The discovery, some few years back, of the foundations of an almost contemporary church at Lyminge and the collateral evidence of German examples lead us to believe that in Western Christendom during the Romanesque period this type of plan was very widely prevalent. We do not remember, for the moment, the precise instances, but we believe that examples exist also in Spain. We cannot believe that the original plan on vellum of the church of the monastery of St. Gall, Switzerland, is an unique example, but rather a sample of the plans sent out by the great Romanesque architectural university of Cluny. To our mind, the double-ended type of plan has been unduly neglected by writers on architectural history, and a comparatively unworked field is here open for archæologists. Although we agree with Professor Simpson that the square east end is not due to the Cistercians, we think that their activity in England during the "transitional" period of Sharpe assisted in the recrudescence of our national form, and we also imagine that

* *A History of Architectural Development.* Vol. ii.: "Mediæval." By F. M. Simpson, Professor of Architecture in the University of London, &c. (London: Longmans, Green & Co. 1909. 21s. net.)

Digitized by Google

it is not improbable that the Puritanism of St. BERNARD and his order, exerting its influence, as it did, at a critical period of development, had something to do with the superiority of English moulding.

Professor SIMPSON disposes, once for all, of PARKER'S theory of the "stone-carpentry" origin of Anglo-Saxon work as at Earl's Barton, and shows how it was derived from the Romanesque work of North Italy.

In conclusion, we commend the second volume of the "History of Architectural Development" to all serious students of architecture. It is clear, logical, and, above all, accurate, and far better value for the money than many lower-priced and carelessly compiled books on architectural history.

STEELWORK.—VIII.

By C. V. CHILDS, A.M.I.C.E.

IN the case of the floors being constructed of cross joists, spaced 2 to 3 feet apart, it is seldom that sufficient headroom can be allowed to permit of the joists resting on top of the girders, consequently shelf angles have to be rivetted to the web of the girders to form a seating for the cross joists; this means an additional expense to the girders in two ways. In the first place one 3-inch by 3-inch by ½-inch angle rivetted to each side of the web adds an extra weight of 20 lb. per foot run to the girder; and in the second place the price is raised by about 25*s.* per ton.

Another expense is incurred by having to notch the top flanges of the larger sized cross joists, in order to keep the floors within a reasonable thickness. It is mainly these three items of expense that allow of the various forms of ferro-concrete floors to compete successfully with floors constructed in the ordinary way of cross joists with concrete filling between them. A mere comparison between the price of the ordinary cross-joist construction—viz. the cost of the cross joists, the concrete filling and the centring—and that of the ferro-concrete floor is not sufficient to arrive at the true value, as the extra weight and cost of the girders, due to the shelf angles, are the chief points that tell in favour of the ferro-concrete construction.

The designer may find the following method of assistance to him in calculating the sizes of the girders. For symmetrically disposed loads it is easy to see at a glance where the maximum bending moment occurs. It is not so easy, however, when the system of loading is a complicated one. In this case the simplest method to adopt is by bringing in the aid of the differential calculus. It sounds complicated, but in reality it is exceedingly simple in practice, as the following example will show. Required the distance x of the point of the maximum bending moment from the point of support of a beam of 20 feet span, carrying a concentrated load of 10 tons 4 feet from that support, and a uniformly distributed load of ½ ton per foot run, equal to 10 tons. The reaction at the point of support nearer to the concentrated load is (8+5=) 13 tons; the expression for the bending moment at a point distance x from this support is:—

$$13x-10(x-4)-\frac{x}{2}\times\frac{x}{2} \text{ or } 3x+40-\frac{x^2}{4}$$

In putting the first differentiation of this expression equal to zero all that it is necessary to remember is that:—

where no x occurs this must be converted into				0
where x	"	"	"	1
where x^2	"	"	"	$2x$

Substituting these values the equation is:—

$$3+0-\tfrac{1}{2}x=0, \text{ or } x=6.$$

By substituting 6 for x in the original expression, this gives, as the maximum bending moment, 49 foot tons.

The same result is obtained in a simpler manner by working from the other point of support; e.g. the bending moment is:—

$$7x-\frac{x^2}{4}$$

$$\text{then } 7-\frac{x}{2}=0 \text{ hence } x=14.$$

So that the point where the maximum bending moment occurs is 6 feet from one support, or 14 feet from the other, in the case of a beam of 20 feet span loaded as stated above.

This is a simpler, quicker and more accurate method than that of employing graphic statics.

Whilst on the subject of bending moments a natural sequence is the selection of the required joist or girder; the tables given in some of the steelwork contractors' handbooks are apt to give the architect a wrong impression altogether in regard to their actual strength. The term "factor of safety" should be abolished entirely, as it is quite a misnomer. The writer has on various occasions been told that engineers design the girders far too heavily, as the joists, &c., will carry four times the load for which they are designed, because the tables state the safe load is one-fourth the breaking load. The breaking load in this case is based on the amount of tensile stress that is required to pull a small specimen test-piece into two pieces. Supposing this stress to be 28 tons per square inch, when the stress is about one-half this amount the elastic limit of the steel has been reached; that is to say, the steel has stretched to a point where, when the pull is released, it will not return to its original length and has taken on a permanent set.

In a beam this is the point where the deflection will cause a permanent sag and the beam will not recover after the load is removed, consequently 14 tons is the crippling stress; this alone should be the determining factor in regard to its strength. In some cases tables have been given based on what is called a factor of safety of three, leading anyone but an engineer to believe the beam will carry three times the amount stated; the breaking stress may have been taken at as much as 32 tons per square inch, so that the beams, to carry the loads stated in the tables, would be stressed to 10⅔ tons per square inch.

The breaking stress of mild steel is more frequently 27 or 28 tons per square inch, and half this amount—viz. 13½ tons—may be the crippling limit, so that the real factor of safety is 13½ divided by 10⅔—that is, 1.25; in other words, an addition of one quarter the amount stated in the tables will cause the stress in the beam to reach the elastic limit of the steel, and the deflection will cause a permanent set—a very different state of affairs from what the tables would imply.

The allowable safe stress should alone be the basis of determining the strength of steelwork.

Joists.—The chief point of difference between English and American joist sections is that, especially in the case of the larger sized joists, the American sections are rolled down to a considerably less weight per foot run, and the width of the flanges is less, than the English sections of similar depth; e.g. the flange of a 20-inch deep British standard joist is 7½ inches in width, and the weight per foot run is 89 lb.; whereas the finishing pass for an American joist is 20 inches deep by 6¼ inches wide, the weight being 65 lb. per foot run. By raising the rolls this can be increased to a maximum of 75 lb. This depth of joist can also be procured up to a weight of 100 lb. per foot, the finishing pass of this section being 80 lb. per foot; that is to say, there are two distinct sets of rolls. In a few of the larger sized joists this system might be adopted by English rolling-mills with advantage, so as to reduce the sizes to more economical sections; the only alteration required would be in the last few passes of the rolls; the breaking down mills would be the same in either case.

Formerly, in the days of wrought iron, the American joists were heavier in section, and new designs were made when steel was introduced. Apparently no alteration was made by English manufacturers, and this accounts for the joists (even in the case of those which have come into existence since that time) being heavier in section.

Within the last few years the sizes of British steel structural shapes have been standardised. Certainly this is a great advantage to the designer, in that it is now possible to make the sizes of the girders such that all firms are able to supply, and prices can be obtained from different firms all on the same basis. Before this occurred each firm almost invariably desired to alter the sections to conform with those they were in the habit of procuring from certain rolling-mills. The result was confusion and delay in rearranging the sizes of the girders, &c., before the work could be put in hand. At the same time, the British Standards Committee might have done a great deal more in the way of making the sizes of the joists such that their strength increases more uniformly in accordance with their sizes, instead of, as apparently has been the case, paying more attention to standardising certain makers' rolls. The moments of resistance of the various sections—that is to say, their strength—should have followed a uniformly increased increment as the sizes grew larger. For instance, in the smaller sections a 4 inch by 2 inch and a 5 inch by 2½ inch would have been far more useful, and might have superseded the present 4 inch by 1¾ inch, the 4¾ inch by 1¾ inch and the

Digitized by Google

5 inch by 3 inch; the latter, weighing 11 lb., is too nearly alike in weight and strength to the 6 inch by 3 inch, weighing 12 lb. So, again, in the larger sizes there is a considerable gap between the 14 inch by 6 inch, weighing 46 lb., and the 15 inch by 6 inch, weighing 59 lb.; also this latter too closely resembles the 16 inch by 6 inch, weighing 62 lb. Their respective moments of resistance are 62.9, 83.9 and 90.7, whereas the strength of the 15 inch by 6 inch should have been exactly intermediate between that of the other two sizes, and its moment of resistance, instead of 83.9, should have been about 77. As it is, the thickness of the flanges of the 15 inch by 6 inch is greater than that of the flanges of the 16 inch by 6 inch. If the rolls for the 15 inch by 6 inch, weighing 59 lb., joist could not have been adapted for this alteration, those for the 15 inch by 5 inch, weighing 42 lb., might have been re-turned; this latter size could have been dispensed with without being very much missed. Certainly there is the 14 inch by 6 inch, weighing 57 lb., joist, but this is not an economical section and is one of the standard sizes it is best to avoid, owing to its not being so generally procurable as the other sections. This size, together with the 12 inch by 6 inch, weighing 54 lb., the 10 inch by 8 inch, weighing 70 lb., and the 9 inch by 7 inch, weighing 58 lb., are more adapted for stanchions than for beams, the two latter so much so that they are almost solely used for that purpose. The 8 inch by 6 inch, weighing 35 lb., joist is but of little use as a beam; it might well have been increased in size to make it essentially a stanchion section, as it is to a great extent at present; but the want is often felt of a size intermediate between it and the 9 inch by 7 inch, weighing 58 lb., joist. Taken all in all, the British standards might have been greatly improved from the designers' point of view.

A few remarks may be made in regard to the spacing of the cross joists. The earlier forms of fire-resisting floors appear to have set the fashion in regard to the distance the cross joists should be spaced apart. In America one of the earliest types of floor was the corrugated iron permanent centreing sprung in between the bottom flanges of the joists in the form of an arch, on which the concrete was laid; this type was superseded by the terra-cotta flat arched floor, which probably still holds the record for the greatest amount of floor area constructed of a fire-resisting nature.

In each of these types the most suitable distance at which to space the cross joists was about 6 feet, and this distance became practically standardised in American design. In England the usual type of floor was that of the cross joists, spaced 2 to 3 feet apart, embedded in concrete; also floors were constructed of terra-cotta tubes resting on the bottom flanges of the cross joists, with concrete filling over, the joists in these cases being spaced 2 feet apart, so that 2 to 3 feet was practically the standard distance in English design. The English tube system was introduced into America, but it found no favour with the steelwork designer, mainly on account of the fact that joists spaced so closely together are not of sufficient depth to provide the desired stiffness when calculated for strength only. This is certainly the great drawback to the cross-joist system of floors; e.g. a 6 inch by 3 inch joist spaced 2 feet apart may be safe to carry a light floor, but is insufficient as regards stiffness. During construction the vibration is very noticeable before the wood fillets and floor boards are laid; these latter absorb to a great extent the vibration of the finished floor; but still it is the lack of sufficient stiffness that militates against the cross-joist system.

When the spacing becomes as wide as 6 feet the size of the joist would be of sufficient depth to make it rigid; the stiffness of a joist depends on the square of its depth whereas the strength depends directly on its depth. As against the wider spacing must be set the difficulty of filling in between the joists; solid concrete makes the dead weight of the floors too heavy. Other light systems may require a false ceiling, which means expense. The terra-cotta flat arch, laid in segments, was almost universally adopted in America to overcome this difficulty; but though it was introduced into England and was manufactured by Messrs. Doulton & Co., it has not been used to any great extent. Since the introduction of ferro-concrete floors and where this type of floor is used the spacing is more a question of the girders than of the cross joists.

(To be continued.)

Mr. Edwin J. Tench, A.R.I.B.A., architect and surveyor, of Station Chambers, Foundry Bridge, Norwich, has been appointed a diocesan surveyor to the Ely Diocese.

THE A.A. PLAY.

By Y. Y.

DULCE est desipere in loco.—The title should have been sufficient warning to me not to carry through my suggestion to her mother that Miss Innocent Trust should accompany me to this year's "Association" play. For in the past she has shown a curious inability to understand certain kinds of jokes. It is, indeed, related of her (though the story has to me something of a chestnut flavour) that not so very many years ago she was reduced from boisterous hilarity to stifled sobs at the pantomime, when in the Harlequinade, after the terrier jumped into one end of a mincing machine sausages came out at the other. This disconcerting tendency to take things literally proved disastrous on the ladies' night. I now realise too late how ominous was the title "The Rise and Fall of Architecture." But on the surface it seemed to promise an educational evening's entertainment for a serious-minded young lady, and one likely to still further heighten the esteem of Miss Trust for the profession to which I, her uncle, belong. How completely these expectations were belied I shall now proceed to show. It is hardly necessary to say that I very quickly realised what was afoot, and was able to enter into the fun of it; but it has been so far impossible to altogether restore Miss Innocent's trust in the profession which she had been encouraged to regard with awe as being full of sacred mystery.

It will be admitted that the sub-title is calculated to mislead anyone as to its true purport. "An up-to-date pageant, being the application of six stages of Architectural Art to present-day practice. Culled from the pages of the past by the Editors of the Purple Patch and brought into harmony with the present by the musical inspirations of Mr. Claude Arundale-Kelly." Nor was the arrangement of the Episodes calculated to arouse suspicion of its serious intentions. Act I. scene 1, The Youthful Prehistoric; (2) The Tactful Egyptian; (3) The Omnipotent Greek. Act II. scene 1, The Mighty Monk; (2) The Eighteenth-century Amateur; (3) The Present Age and the Descent of Man.

But the trouble began as early as the Prologue, for we were told:—

In Act I. we show that "art" isn't wanted at the start—
Simply "cheek."
Then as art becomes a fact, we require a little "tact"—
Just a streak.
But when art its summit reaches, true "forbearance" great it preaches;
Act II. will show you symptoms of its wane.
Dilettanteism spreads—in scene 3 our art is dead;
Try "advertisement" to set it up again.

The evil genius of Architecture is clearly proved by this historical review to have been the Purple Patch as far back as the dim days of palæolithic man. It was he who, announcing himself as a messenger from the gods, put strange implements into the hands of Ari-Ba and told him that he was to practise the profession and preach the art of architecture. And it is the Purple Patch who prompts this bewildered mortal how he is to bluff his first clients Ung and Boo, who are wanting immediate shelter after being evicted from their ancestral cave by a Great Green Beast.—Cheek.

In the course of the centuries which separated the Stone Age from the era of Ancient Egypt the status of the architect has so improved that he and his colleagues have formed themselves into the order of priesthood known as Riba. The high priest Manrula, F.R.I.B.A., has learnt by bitter experience of the waywardness of lady clients, and especially that of Queen Hatezu, who wishes to build a temple to Christabel. The queen is never of the same mind for two successive hours as to what kind of place she will have. Finally, she commands that a commencement be made with the foundations and all the rough walls; when these are ready she will decide what the superstructure shall be like. The distracted architect is again saved by the crafty Purple Patch, who comes disguised as interpreter to a foreign prince. His advice is for Manrula to erect the temple according to his own design, and then for

Digitized by Google

him to go to the client and extol her judgment to the skies, for "she'll soon believe 'twas all her will," and so must always be constrained to call it good. Here is TACT.

With its help you make a client, most uncertain,
Decide on just the thing you want to do;
By its aid you make a builder, old and cranky,
Quite cheerfully adopt all methods new.

Although architecture rose to its greatest height in the time of the Greeks, it is evident that the fatal influence of the PURPLE PATCH has been insidiously poisoning the honest minds of its practitioners. The incident taken from history is the little-known arbitration case between PERICLES (to whose generosity the Parthenon owes its existence) and BRYX, who carried out the contract. PERICLES claimed 30,000 drachmae under the penalty clause for delay, and also maintained that the temple was not up to specification. The case is being heard by CALLICRATES, P.R.I.B.A., and his partner ICTINUS, who has been made a partner so that he may do all the dirty work of the President's immense practice. The case goes hard with BRYX, especially as CALLICRATES wants it finished in time for lunch. The witnesses for the plaintiff are many and their evidence overwhelming. But the builder at last gets a hearing at the suggestion of the PURPLE PATCH. His defence is that, in addition to finding the marble harder than expected, and the frieze longer than it ought to be, he was hampered in his work by a slip of a girl who sat chatting on the scaffolding the whole day long. He appeals to CALLICRATES to make allowance for a lover. The arbitrator thereupon adjourns the case so that the beautiful damsel may be brought into court—FORBEARANCE.

By the fifteenth century the profession had deteriorated in something more than honesty, for the ecclesiastics who won fame as architects are nothing more than figureheads. Witness the behaviour of Sir THOMAS DE TUFTON, abbot of Blastonbury, who pretends to be superintending the erection of the south transept of his abbey. Progress in the operations is rudely checked by the arrival of the Sheriff's Clerk, who serves injunctions to restrain the monks from further trespass on the light and air of their neighbours by continuing to erect the three towers, which are being set up to mortify the monks in the neighbouring rival Benedictine abbey. The dilemma is solved by the PURPLE PATCH, the abbot's jester, who whispers that the official is something more besides the Sheriff's Clerk. He proves to be also the urban district surveyor and open to reconsider his complaint that no plans have been lodged. The rich benefactor once more finds that "when steel fails gold is the best metal to use"; in fact, to employ the auro-concrete system of construction. The difficulty with the local authorities is thus overcome by TACTICS.

Some three centuries later the PURPLE PATCH is at hand when ADDISON, in despair as to finding a subject for his weekly article, offers his artistic soul for an inspiration as to how to tilt at architects. The pledge is accepted, and ADDISON is told to "imagine a house designed as a place to live in: not an exercise in gentility, not an illustration of what its master would like to be thought, but a place in which a man of plain good sense might live, and move, and have his being"—DILETTANTEISM.

Miss INNOCENT TRUST had only been slightly affected by all this, for the rather damaging incidents that had been mirrored on the stage belonged to a dead and gone age. But the last scene was a painful reality to her with its twentieth-century garb and thoughts. It showed the exhibition of *Daily Mail* Ideal Home Competition drawings at Olympia. The prize-winner, Mr. SNATCHALL, has been living for the past two years on his articled pupil's premium. But when he pins his office card on his drawings orders crowd in. This idea is due to the lesson learnt as to self-advertisement from Messrs. SPARING & FLASHY, decorators, builders, and whatnots, who had almost ousted him out, and also thanks to Mr. SNATCHALL'S own energy in touting for clients. He has likewise discovered—

That clothes give a sense of stability;
We have now discovered that
A tail coat and good top hat
Are worth more than artistic ability.

The PURPLE PATCH, in order to show how little architects have really advanced in all these years in execution and the British public in powers of appreciation, conjures up the cottage that ARI-BA had designed in the palæolithic days, to find that (as STEVENSON wrote), the brick seemed to be blushing in the walls, and the slates on the roof to have turned pale with shame. The PURPLE PATCH then delivers this warning:—

Oh! you architects, you must be going blind;
Can't you see you're getting left centuries behind?
Your antiquated methods do not pay.
The wholesale art-providers soon will have you on your knees;
Your practice is already growing smaller by degrees
And beautifully less.
You'll be in a horrid mess
And a pickle when they come to you and say:—
Oh! you architects, you must be going blind;
No good to cuss,
You're left by us
Hopelessly behind.

Miss INNOCENT left the King's Theatre, Covent Garden, a sadder and a wiser maid.

The principal parts were sustained, and well sustained, by Mr. F. DARE CLAPHAM and Mr. G. B. CARVILL, the former in many aspects, but always the architect in each successive age—ARI-BA, the first architect in the prehistoric age; MANRULA, F.R.I.B.A., in the reign of the Egyptian Queen HATEZU; CALLICRATES, architect of the Parthenon and P.R.I.B.A.; Sir THOMAS DE TUFTON, a great architect and abbot of Blastonbury in the Mediæval period; and finally SNATCHALL, architect and designer and winner of the *Daily Mail* Competition. Mr. CARVILL, as the PURPLE PATCH, the organiser of the play, is throughout the piece the guiding spirit that ever prompts the architect and supplies him with the motive force—HUMBUG.

IRISH ARCHÆOLOGY.

IN Alexandra College, Earlsfort Terrace, Dublin, Professor Wm. Ridgeway, D.Litt., LL.D., delivered last week a series of three lectures dealing with the subject of Irish archæology, in connection with the Margaret Stokes Memorial Lectures for 1909. The title of the first lecture was "Ireland in the Bronze Age."

Professor Ridgeway outlined at the commencement of his remarks the lines upon which his course of lectures would proceed. The first period of Irish archæological history with which he would deal would be that of the earliest times, covering the stone and bronze ages, at the same time drawing attention to the question of the ethnology of this country. In his second lecture he would deal with a further stage of the development of the bronze age, and the final lecture would deal with the early mediæval period of Irish archæology, coming down to about the year 900. Ireland, of course, had her stone age, though not like that of the sister island. Ireland in those far-off days was detached from the mainland by stormy seas, so that here in this country no real palæolithic instruments had been found. Britain, on the other hand, was in those same days joined to the mainland, and hence there were found in that country remains of the palæolithic times in the form of ancient domestic implements and of weapons. Such monuments of the past spoke to them eloquently of what happened to man in those old ages. He had to struggle, not so much with the elements, although there were at times huge natural cataclysms. He had, rather, to struggle with the mammoth animals of the palæolithic ages, and all too often, it would appear, the beast had the best of the struggle. The new stone period was the first stone age which they had in Ireland. In that stage of the history of man a great change had taken place, and the rude implements of the earlier times had been very largely replaced by polished and pointed implements of attack and defence. There was a wonderful sameness about the implements of the palæolithic age; but when one came to the neolithic period man had learned, at least in the southern regions of Europe, to make better implements, and the methods of using those styles of implements were better known to archæologists than those adopted in regard to the earlier ones. The lecturer having shown on the screen examples of the various classes of weapons used in the Irish stone age and in the succeeding

Digitized by Google

bronze age, proceeded to state that in the matter of the manufacture of bronze implements Ireland at no time in the course of the bronze or iron age had been dependent upon Britain. It had been a fondly cherished idea of the people connected with the British Museum that everything in the matter of Irish culture in that particular branch depended entirely upon the supply making its way into Ireland through Britain. All the evidence, however, was directly to the contrary, and went to show that Ireland had always direct communication on her own account with the Continent, and particularly with either Spain or France. The fact that they found in North-Western Spain axes of the type of those in use in Ireland in her bronze age showed that Ireland was not indebted to Britain for her implements, but that she had direct communication with the mainland. In the case of the Irish bronze axes they frequently found specimens of them beautifully decorated and beautifully engraved—the most beautiful things, in fact, in the way of such implements to be found in any part of the world. The lecturer next showed examples on the screen of ancient Irish bronze spears and daggers, the different forms of construction of which he pointed out, explaining the nature and properties of the composition of bronze, and its adaptability to such a use as the manufacture of those ancient implements with which he was dealing. As he did not accept the theory of Ireland owing her progress in those matters to help from Britain, neither did he accept the theory that those arts might be, in some measure, traceable to the Phœnicians, a suggestion which had been so frequently put forward. He, personally, did not believe that the Phœnicians had ever passed the Bay of Biscay, and he had never been able to ascertain that any single ancient article which could be described as Phœnician had been at any time found in Britain. "However," added the lecturer, "the Phœnician dies hard. He has in his time played many parts, and I have no doubt that he will often be revived in the future."

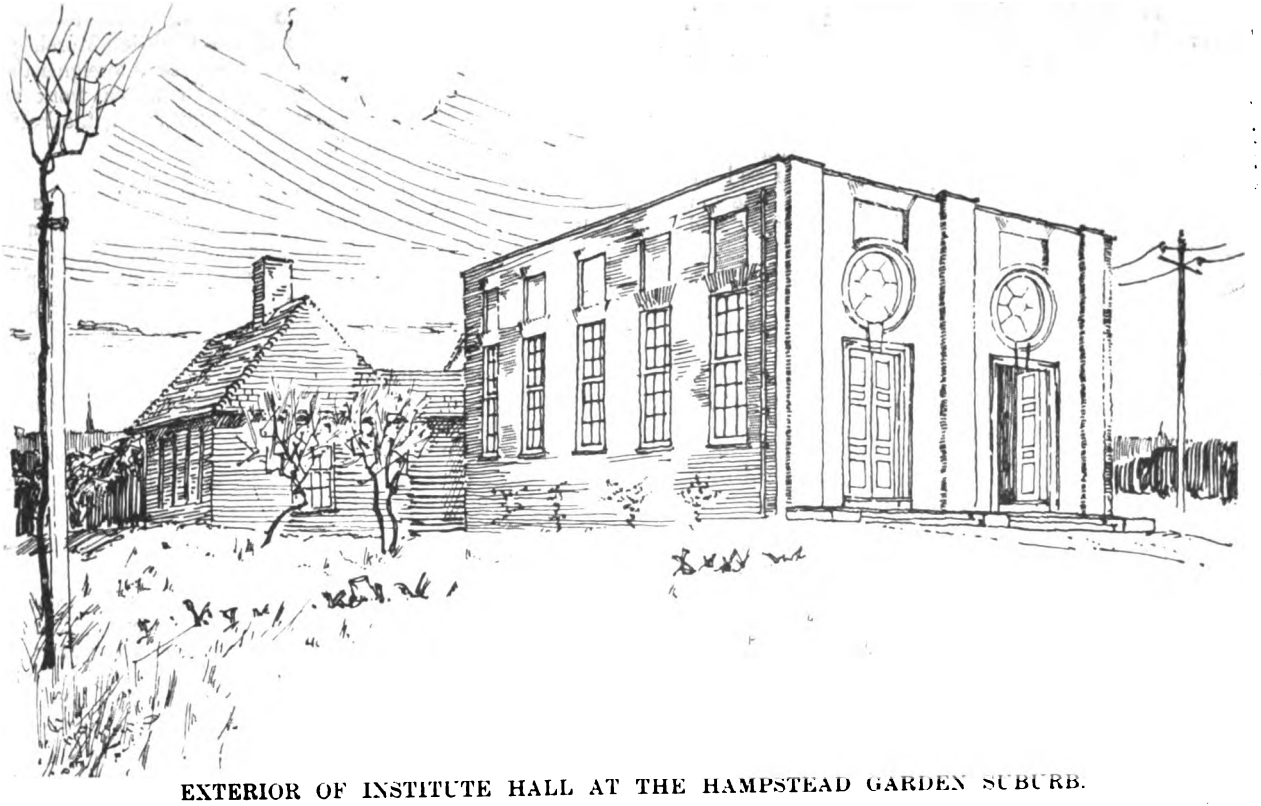
The second of the three lectures was entitled "Ireland in the Early Iron Age."

Professor Ridgeway pointed out that in the whole history of the progress of mankind from one stage of development to another no more important step had ever been taken than that initiated by the men who first discovered the power of working iron. The question was, Where did that power first come into use amongst men? It had for long been held that the discovery of the uses and the working of iron so far as Europe was concerned was a gift to that Continent from Africa or from Asia. He held that the art of working in iron had not come into Europe from those places, but that, on the contrary, the use of that particular metal had been evolved in Europe itself, and that, from the earliest period of the iron age, the working of that metal had been in the hands of Celtic peoples, who carried the knowledge of the art with them wherever they went. There was evidence that iron was in use in Central Europe long anterior to the year 1500 B.C. About 400 years before Christ the Gauls invented a species of ornamental work which distinctively belonged to the iron age, and of which traces had been found in Ireland, including six examples of a peculiar and highly ornate form of brooch, three of which had been discovered in the celebrated Navan-rath, itself the centre of the exploits of some of the ancient heroes of Ireland. The epics relating the adventures of those heroes, about whose existence there could be no doubt, though their doings might have been very greatly exaggerated by those who had written about them, showed them as users of chariots in the accomplishment of their warlike exploits. These chariots were examples of the methods adopted by warriors in the iron age, before the introduction of cavalry as a means of fighting, and proved conclusively that Ireland shared, to no small extent, in the progress and development which was to be found in that particular period of the world's history. That fact was further borne out by the examples which had been discovered of ancient Irish armour, and of the specimens of swords and other warlike implements which were fashioned from iron. In dealing with those matters the inquirer was once again, as in the case of the progress of the bronze age in Ireland, afforded proof that the art of working in iron had been introduced to this country without having come here from Britain.

Professor Ridgeway, in his concluding lecture, dealt with the subject of "Ireland in the Middle Ages," and stated at the commencement that by the combined study of ancient literature and of archæology great advances could be made in the matter of historical research. Whilst the archæologist lent a helping hand in securing a proper estimate of the ancient life of a people, he, on the other hand, owed a great debt to the scholar and to literature. In the elucidation of those matters in which they were on the present occasion interesting themselves, archæology and literature must go hand in hand. If archæologists could only get something substantial in the matter of the history of the countries whose archæological records they were investigating, that fact would be of great assistance to them. In the case of Irish archæology they could attain more and more to that end as they advanced in the study of the various cycles of Irish poetry. The cycles of Cuchulain and of Conchobar afforded them good reason for believing that the poems dealing with those periods were shaped at dates not very far removed from the times in which the events narrated therein were supposed to have taken place, and they brought them back to the end of the first or second century after Christ. There was no literature to be found in Europe north of the Alps which could compare in wealth of information with the ancient Irish poems. Teutonic literature had nothing to compare with those Irish works. Thus they would see the extraordinary importance of a work like the "Tain Bo," which represented the life of a certain number of those ancient Celts who had played such a prominent part in the history of Central Europe from the earliest dawn of history. The lecturer then proceeded to deal with the subject of the literature of the Ossianic cycle, which, he said, afforded most interesting and instructive glimpses into the lives and customs of the people who had lived in this country in that particular period. The same was to be said regarding the literature dealing with the exploits of Finn and the Fionna. Works like those were amongst the oldest literature in Europe, and some of them went back far beyond any of the records contained in the oldest known forms of Teutonic literature, and had given a literature not to be found in any country of Europe in its richness of detail and in its importance. He was glad to see that that literature was being studied by people at home as well as by foreigners. But the ancient literature of Ireland must be studied in connection with the archæology of Ireland in order that certain important definite results might be arrived at. They had Irish scholars to-day who were doing much useful work on both the literary and the archæological sides of that very important matter, scholars like their chairman, who was doing so much for the development of the literary and ecclesiastical side of the subject. All that work would lead up to something being accomplished which would show in time the extraordinary heritage which the people of Ireland had in their native land.

The abstracts of the above three lectures have been taken from the reports in the *Irish Times*.

THE LAND REGISTRY.



AT the annual meeting of the Land Law Reform Association held last week in the Conference Room of the National Liberal Club, the following resolutions were put to the meeting and carried:—

1. That in view of the fact that the system of compulsory registration of title that has been on trial as an experiment in the County of London since January 1899, has not proved satisfactory, and that as a consequence a Royal Commission has been appointed to consider the subject, and further in view of the fact that the Land Registry officials have since giving evidence before the Commission found it necessary to completely alter the practice, and to seriously increase the registration fees, this meeting is of opinion that the Privy Council should forthwith exercise the power they possess to suspend the operation of the Order applying compulsion to the County of London, so that pending the report of the Royal Commission, property owners may be left free to register or not as they deem best in their own interest.

2. That copies of the foregoing resolution be sent to the Lord Chancellor, the Privy Council, the Chairman of the Royal Commission, the Attorney-General, and the London County Council.

Mr. L. Harcourt, M.P. (the First Commissioner of Works) in reply to a question as to what progress has been made with the Queen Victoria Memorial in St. James's Park, and by what date it is likely to be completed, stated last week that a large portion of the sculpture was completed, and arrangements have been made to begin fixing it as soon as possible. The fountains and marble work around the base are finished, and it is intended to remove the hoarding during April, when they will be visible to the public. It is not possible to name an actual date for completion.

EXTERIOR OF INSTITUTE HALL AT THE HAMPSTEAD GARDEN SUBURB.
Edwin L. Lutyens, Architect.

INTERIOR OF INSTITUTE HALL AT THE HAMPSTEAD GARDEN SUBURB.
Edwin L. Lutyens, Architect.

On Saturday last the Institute Hall, built by the directors of the Hampstead Garden Suburb from the designs of Mr. Edwin L. Lutyens, was opened by Canon Barnett for the use of all the inhabitants of the new community. This building is but the first instalment, as it now stands, of what is anticipated in the future, a group of buildings providing an educational and recreative institution for the suburb, and comprising museum, galleries and library, in addition to the hall now provided. Our sketch shows therefore merely the embryo of the future scheme. The hall is built of red brick (on the faces shown) with stone for the architraves to the doorways and the circular panels over. The roof is flat. The interior of the hall is very refined in treatment and finished at present in white plaster.

NOTES AND COMMENTS.

HIS MAJESTY'S Government has adopted a welcome change of policy by advising the appointment of a Royal Commission to assist the Board of Trade in taking measures to ensure the proper representation of British Arts and Industry at the forthcoming International Exhibition at Brussels in 1910 and at Rome and Turin in 1911. The only architects whose names we note on the list of the Commissioners are Sir THOMAS DREW and HIPPOLYTE JEAN BLANC, Esq., the former as President of the Royal Hibernian Academy of Painting, Sculpture and Architecture, and the latter as Deputy President of the Royal Scottish Academy of Painting, Sculpture and Architecture. Whilst we acknowledge these two gentlemen as worthy exponents of the art of architecture in Ireland and Scotland, we regard it as an insult to the "Mistress Art" that she should be represented, on the advice of His Majesty's Ministers, only because two of her sons are so well acknowledged as artists as to be selected to preside over painters and sculptors. Why should not architecture be represented by a member of the Royal Academy or by a present or past President of the Royal Institute of British Architects? The Brussels Exhibition is to include an art section, and the Exhibition at Rome is to be wholly devoted to art and archæology. Is Great Britain to surprise her Belgian and Italian hosts by leaving out architecture as one of the arts practised in this country?

SIR F. BANBURY'S proposal in the House of Commons to omit from the London County Council (General Powers) Bill the clause granting a right to appeal to the County Council from a decision of a district surveyor by any person dissatisfied with that functionary's decision in regard to buildings of iron and steel skeleton construction has, to our mind, strong justification. The position of the new order of district surveyors and the method of their appointment makes them increasingly officials of the County Council rather than independent professional men, and the Tribunal of Appeal, which is independent, is the only authority to whom any appeal from the decision of a district surveyor ought to be allowed.

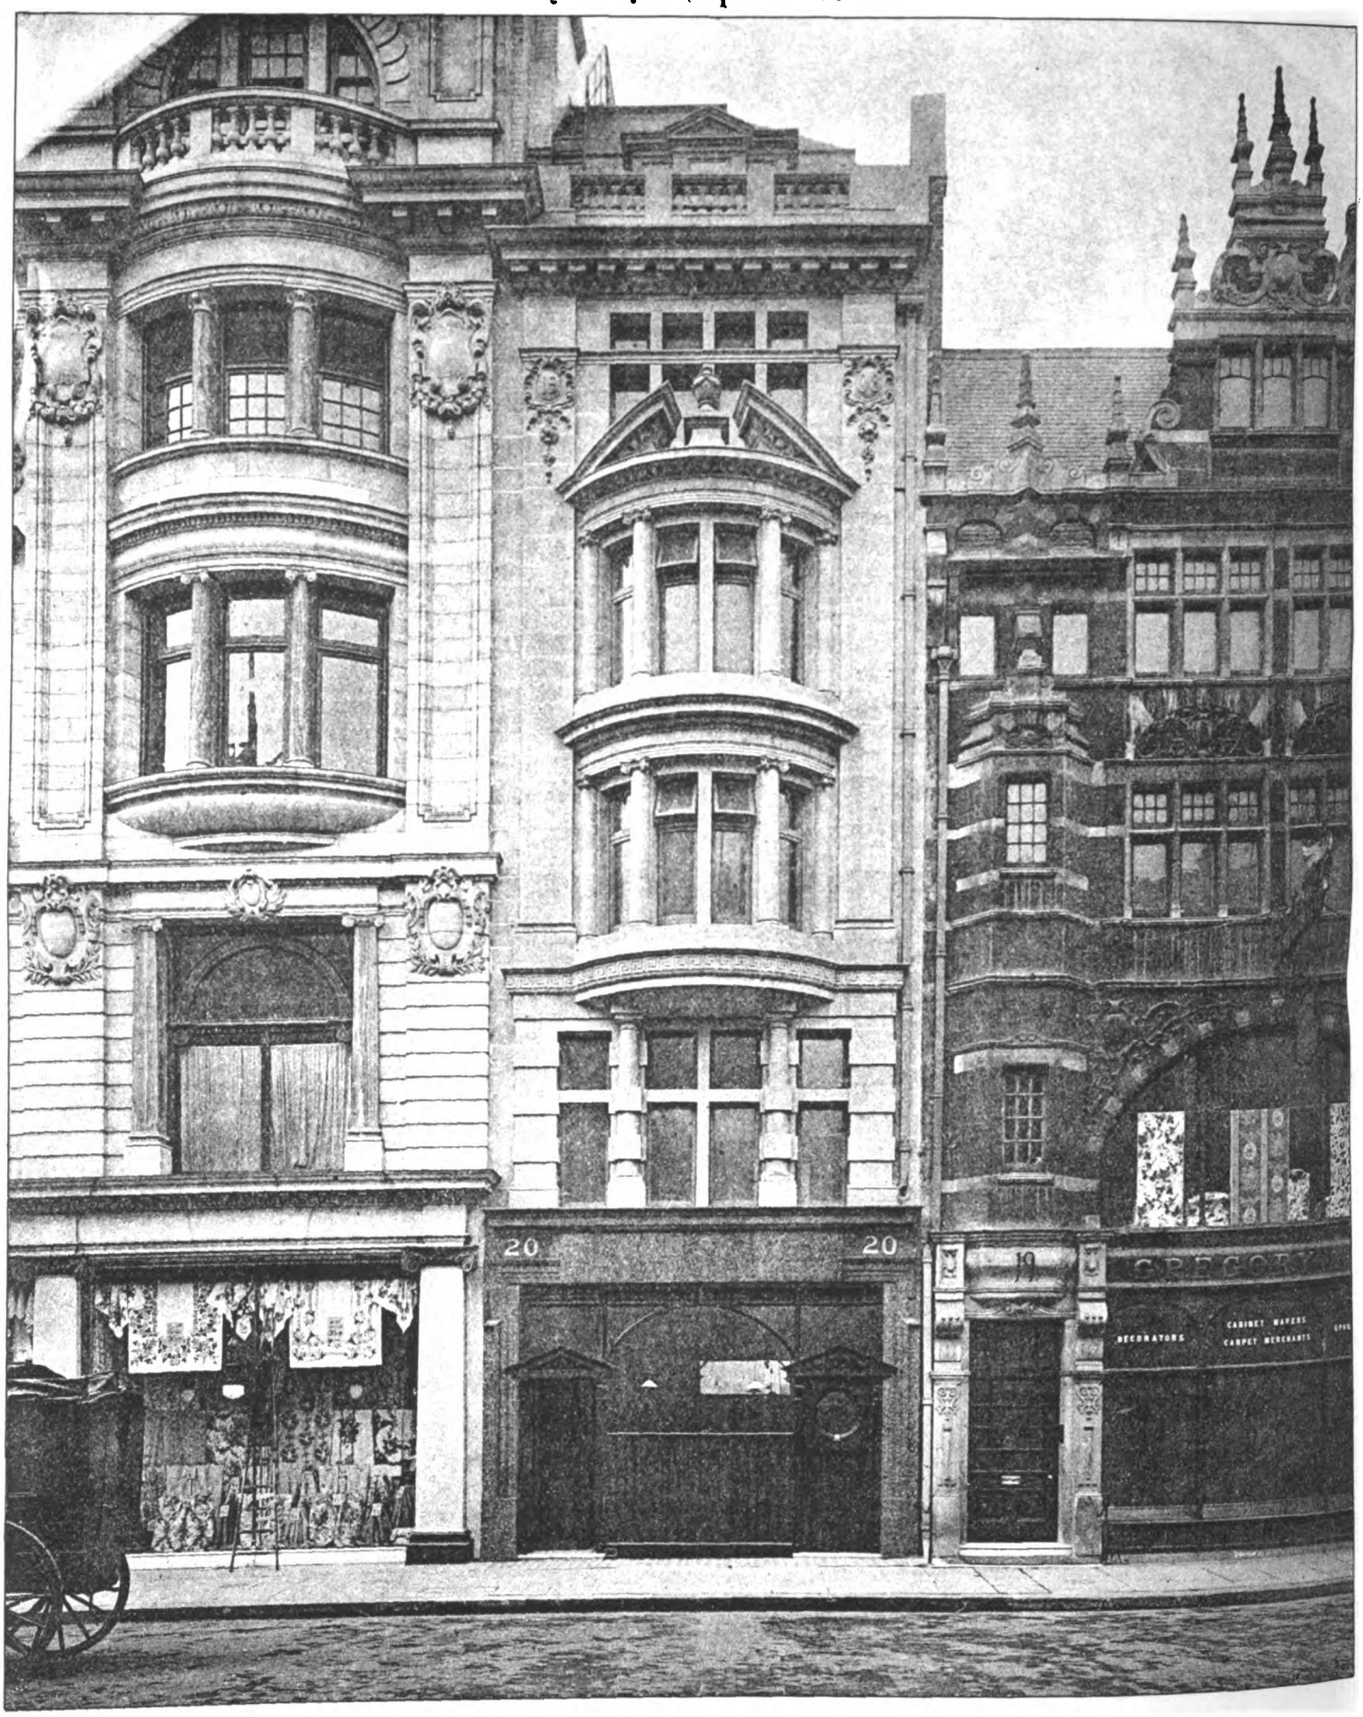
PROFESSOR HERKOMER says that in the past Art was an integral part of life, that now it is an "extra," and is charged for accordingly. He suggests that the remedy is to follow the example of his countrymen, the Bavarians, who send round the country collections of reproductions of modern and past masters, and encourage the peasant to buy copies from an exhibition in the local school-house. But is the Professor right? Has not the Philistine begun to recognise that oil painting is not the only form of art? The success of the Arts and Crafts movement would seem to answer this question in the affirmative, as does the increasing readiness of the public to prefer artistically designed furniture, textiles, and jewellery. The numerous well designed small houses that our younger architects are producing in such profusion in garden cities and suburbs are doing more to produce an appreciation of art by the people than any number of reproductions of the works of modern masters of picture painting, and the speculating builder, shrewd man as he is, has grasped the fact that an architect's house sells better than the atrocities of which he could readily dispose ten or a dozen years ago.

HIS HOLINESS Pope PIUS X. on Saturday last formally opened the new picture gallery at the Vatican, which is approached from the back of the building in the Vialone di Belvedere, and is on the ground floor, immediately below the Vatican Library. The architect of the gallery is Commendatore CONSTANTINO SNEIDER, and the collection and arrangement of the pictures is the work of the late Professor SEITZ and Professor PIETRO D'ACHIARDI. The arrangement of the rooms is mainly chronological, one room being devoted to Byzantine and trecento artists, one to those of the quattrocento and cinquecento, one to the seicento painters. Other rooms are given respectively to works of the Umbrian-Marchegian schools, to those of RAPHAEL and to those of foreign artists. The general superintendence of the whole work was assumed by Monsignor Marquis MISCIATELLI, the Prefect of the Apostolic Palaces.

THE Royal Scottish Museum at Edinburgh is the fortunate possessor of a large collection of specimens of pottery of the mysterious Incas of Peru. This has been recently presented by Mr. THOMAS COLSTON, and supplements the bronze and silver work of the same age given by Mr. COLSTON some ten years ago. The marked resemblance between the decorative work of the ancient Peruvians and that of Egypt is a very interesting feature, and lends colour to the theory that there was some connection between the peoples of the two countries, far distant in space though they were, whilst no little information is afforded by this pottery as to the fauna and flora of Peru under the Incas.

IT seems that the commission of eminent experts appointed by the Italian Government has decided that the Government has so many important excavations on hand that it would be quite premature to attempt to commence upon Herculaneum, which, however rich it might prove in discoveries, they say can only be adequately excavated at an enormous cost. Thus, having refused the assistance of Dr. WALDSTEIN, the Italians now find they cannot themselves do the work of unearthing Herculaneum, and they are content to believe that as the remains of that city have lain where they are for nearly 2,000 years, they will be quite safe for another century or two. They seem to ignore the fact that eruptions of Vesuvius have not ceased, and that possibly a fresh flow of lava might cover the site of Herculaneum.

THE Royal Victorian Institute of Architects evidently has to fill in Melbourne the functions of both the Institute and the Association in London, for at their annual conversazione, of which an account appears in the number of the Journal of Proceedings now to hand, they not *only* distributed prizes for the annual students' competitions—and very good are the winning drawings—but entertained themselves with an architectural comedietta, "The Blotted Blot," quite on the lines of those initiated by the Architectural Association. The plot of the play was a competition, limited, between a clever but struggling young architect, NORMAN CROCKETT, and a successful but unscrupulous architect, ADOLPHUS TUCKPOINTER, for an asylum for Unelected Politicians at the new Federal Capital of Never Never. Of course youth and virtue triumphed.



WE noted a few weeks ago that the New Yorkers proposed to restrict the height of tall buildings in that city to 350 feet. We now learn that the municipal authorities have refused to adopt the restriction, and decided that there shall be no limit to height, provided sufficient allowance is made for light and air to adjacent buildings. This provision is the crux of the whole question. If one man erects a skyscraper his neighbours are prejudiced because they cannot do the same without injuring his light and air. But "jumping the claim" is recognised in the States as a justifiable proceeding.

WATER paints or washable distempers sometimes give unsatisfactory results on newly plastered work, and treacly tears run down the walls. The reason is simple: many of these compounds contain a certain amount of oil, the lime in the plaster combines with which to form a soap. Hinc illæ lachrymæ. Others are themselves saponaceous, and the wet and still active lime plays the part of a reagent on their chemical composition. The best prevention of the trouble is to wait till the wall is dry and the lime carbonated and inert.

ILLUSTRATIONS.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL—LIBRARY.

MR. PAUL WATERHOUSE, the architect of this building, in response to our request for some particulars, writes:—"The difficulties of this design consisted in the fact that very large rooms, like the library and the museum, had to be combined in the same building with the nurses' quarters, which are, for the most part, rooms about 10 feet square. It was essential, in my opinion, that the complete composition should be of an Academic character and of balanced proportions. I therefore disguised the differences of window sizes and floor heights by making a large pilaster order the dominant feature of the wings and of the centre. The nurses' home is in the end furthest from the spectator (in the published illustration), and the Gower Street front contains the gymnasium (basement), library, museum, and on the upper floors rooms for research, anatomy, &c. The large lecture theatre, chemical class-room, administrative and official rooms, and theatre class-rooms for microscopic work are grouped in the central portion. The building contains, besides the scientific and technical accommodation, various clubrooms for the convenience of students, as well as a board room for the meetings of the governing committee. Between the nurses' home and the school is a small house of residence for medical students engaged in obstetric work. The contractor was Mr. CARMICHAEL, and the clerk of works Mr. KENNEDY. The whole undertaking owes its realisation to a generous gift by Sir DONALD CURRIE, whose portrait occupies the place of honour in the library."

ST. AGNES CHURCH, FRESHWATER, I.W.

THIS church, which was erected last year, was an attempt to produce a building which should be worthy of its purpose, and form a picturesque feature in the landscape, but should be at the same time inexpensive. It is, in fact, a contribution towards solving the problem of "cheap churches," coming year by year more to the front. With such a motive simplicity is imperative, but the materials are good and the work substantial. The walling is of local stone both inside and out, a large portion of which was taken from a demolished house in the parish. The tiles of the roofs of porch and turret are from the same building. The roof is covered with reed thatch. The floors and roof are deal; the remainder of the woodwork is English oak. The north front with porch and vestries faces the road. It is lighted and heated by gas. The site was given by Lord TENNYSON, on whose estate the church is built. The cost of the building was about 1,000*l*. The seating accommodation is for 150. Mr. ISAAC JONES, of London, was the architect, the quantities were supplied by Mr. J. N. NEWMAN, and the builders were Messrs. BROS, WHITE & Co., of Freshwater.

DESIGNS FOR COTTAGES.

THE cottages are of 9-inch work, with cream-coloured rough-cast, local plain tile roofs, red tile sills and green painted woodwork and leaded casements. The buttresses are put only where structurally necessary. The pair of cottages are near Reading. Mr. ARTHUR WHITCOMBE, A.R.I.B.A., is the architect.

NEW PREMISES, OLD CAVENDISH STREET, W.

THIS building, which has just reached completion, has been erected for Mr. JOHN SOPER, window-blind manufacturer, by Mr. W. J. MADDISON, of Clarkson Street, Canning Town, from designs by Messrs. BULMAN & DEAR, architects, of 67 and 69 Chancery Lane, W.C., who have been influenced in their choice of materials by the adjacent buildings. The ground-floor frontage is of royal blue granite (polished), and the shop front and doors of polished teak. Above the ground floor the whole of the front elevation is built of blue Forest of Dean stone. This stone has hitherto not been much used in London for elevations, owing to its cost, but of late, by the aid of the most modern machinery and appliances and an enormous development of the quarries, the finished price has been very considerably reduced, and Forest of Dean stone can now be put on the London market at a figure to compare favourably with Portland or other first-quality stones. For its wearing properties, blue Forest of Dean stone is renowned as one of the finest and most durable sandstones in the country. It withstands the London atmosphere most successfully and quite equally with Portland, and, contrary to all other stones, it weathers clean and retains its natural colour. It is wonderfully durable, and has been known to retain the tool-markings after hundreds of years' exposure, as can be shown in many old buildings throughout the country. The stone has been quarried, worked and fixed complete by the Forest of Dean Stone Firms, Ltd., of Bristol, and 13 Buckingham Street, Strand, W.C., who own a large number of quarries in the Forest of Dean. The carving has been executed by Messrs. E. J. & A. T. BRADFORD, of 62A Borough Road, S.E. The upper part of the building is divided from the shop by a concrete floor, and consists of five storeys, which will be used as offices and showrooms. The staircase and doors therefrom are of teak fire-resisting construction, and the stairs are lighted by means of borrowed lights in the doorways filled with electro-glazed fire-resisting glass panels by the Luxfer Prism Syndicate, who have also supplied the tiled-pavement lights. From the first floor the upper storeys are also reached by means of an automatic electric passenger lift on STIGLER'S patent, supplied and fixed by Messrs. SPAGNOLETTI, Ltd., of Shepherd's Bush. The Coalbrookdale Co. have supplied the "Tilt fires" and mantel registers used, and Messrs. LEGGOTT & SONS the door and window furniture throughout.

ARCHITECTURE AND THE CRAFTS.

MR. H. PHILLIPS FLETCHER, F.R.I.B.A., the architect to the Carpenters' Company, as chairman of a recent lecture to plasterers at Carpenters' Hall, in proposing a vote of thanks to the lecturer said that from his experience in different parts of the world he believed that the British craftsman, when given the time and the opportunity, was still the best in the world, but that owing to the stress of modern conditions he had fewer opportunities than heretofore. A debt of gratitude was due to the Carpenters' Company for stepping into the breach and trying to neutralise to some extent the decadence of apprenticeship by the establishment of their craft schools and the founding of lectures by eminent craftsmen. The problem of such modern conditions must be faced, and it was useless to sit down with folded hands to deplore the present condition of things. It behoved us all to be up and doing our utmost to turn out good work, and to tackle the problems of to-day as they were presented to us, not in the leisurely manner of our ancestors, but in such a way as to conduce to the benefit and enjoyment of our clients who, as they paid the piper, were entitled to call the tune. It was our duty to try and get them to appreciate the things that are inherently good and refined, or in other words to call for the right tune, which latter was not often improved by being produced upon a German band.

Architecture had been ignorantly described as ornamental building. This was entirely contrary to the proper spirit of architecture, and indeed good architecture often consisted of buildings without any ornament at all. If the ornament did not arise in the course of the constructive efforts of the architect, but merely had an appliqué appearance, it must be an outrage to a cultivated mind and the inappropriate ornamentation of many buildings of the present day was the cause of their being so unsatisfactory.

Mr. Fletcher mentioned that he had that afternoon received a catalogue containing designs in iron which obviously had been executed by someone who knew nothing at all about iron, and the result was that the draughtsman had produced drawings which were entirely incongruous, and must show to any practical man blatant ignorance of the first properties of the metal.

While it was impossible for architects to be absolute masters of every craft, they must at least understand the properties and the feeling of materials before they attempted to convey to craftsmen and manufacturers their ideas in design, and indeed they must try to be mates of all trades and master of their own; or in other words, to understand something about everything, and everything about something.

A LESSON FROM THE PAST.*

(Concluded from last week.)

THE decline of what has been termed "organic" architecture was attended by the development of a style of which a great deal is seen and heard at the present time. Precise and scholarly, with a close affinity to the articulation of antique art, it is devoid of virility, and rises superior to "constructional and actual necessities." With such attributes and with details that can readily be expressed on paper, when they are not tortured into some wild freak, it is well within the capabilities of the modern practitioner and the modern workman; therefore it is not surprising that the beguiling influence of its later phases should now be almost universal.

The German poet Goethe, whose mind, as you know, was pre-eminently receptive and discriminative, visited Vicenza 120 years ago. He there saw the finest buildings by the last great master of the Italian Renaissance. Of these he says:—"When once one stands in the presence of these works one immediately perceives their great value, for they are calculated to fill the eye with their actual greatness and massiveness and to satisfy the mind by the beautiful harmony of their dimensions. Therefore I say of Palladio, he was a man really and intrinsically great, whose greatness was outwardly manifested. The chief difficulty with which this man—like all modern architects—had to struggle was the suitable application of the orders of columns to buildings for domestic or public use, for there is always a contradiction in the combination of columns and walls." (An old-fashioned objection that we hear nothing of nowadays.) "But with what success," Goethe proceeds, "has he not worked them up together! What an imposing effect has the aspect of his edifices; at the sight of them one almost forgets that he is attempting to reconcile us to a violation of the rules of his art. There is, indeed, something divine about his designs, which may be exactly compared to the creations of the great poet, who, out of truth and falsehood, elaborates something between both and charms us with its borrowed existence." Again, he says:—"The noble buildings which Palladio has erected are disfigured by the mean necessities of the people; the plans of most of them exceeded the means of those who undertook them, and these precious monuments of one lofty mind are but little adapted to all else around." At once a eulogy and a condemnation. The architect, you see, has now become a great personality; he builds for fame, the structure is his monument, the necessities of the people are ignored, and the Gothic town hall at Vicenza is henceforth buried in Palladio's "imposing" arcades.

About 100 years later a mathematician and astronomer named Christopher Wren was entrusted with the important task of rebuilding a great part of the City of London, after the fire that succeeded a calamity like that I have referred to of the fourteenth century. It is not my purpose this evening to enlarge on the career of this great man, whose works are so well known to you, but merely to remind you of the fact that throughout his extensive practice he accepted the prevailing fashion of his day, and by a scientific adjustment of slender materials produced artistic effects, stamped with individuality, yet charmingly varied to suit the exigencies of the site and the purposes of the building.

Wren's works present a happy combination of that "truth and falsehood" so much appreciated by the German poet; but, partly owing to the fact that the English architect had seldom the leisure or the means to elaborate his designs beyond their natural development, it is the "truth" that is predominant. The germs of decadence—inseparable from a Renascent style—are present, but the high-water mark of constructive skill had been reached, in combination with a definite and artistic expression.

Thus throughout the ages, say, from the hall at Karnak to that at Westminster and onwards to the eighteenth century, the capacity to produce really interesting work, and an absence of that aptitude—so prevalent in the present day—to produce anything uninteresting, seem to have been universal. In this connection it should be remembered that not only were the social conditions simpler than they are to-day, but the amount of architectural building was comparatively small; the materials used were the natural products of the country; the style of building was universal and so was the system of workmanship.

The world has turned round many times since then, and to-day constructive skill has overreached the legitimate capabilities of honest material. We are invited to leave the path of architectural rectitude for the labyrinthic deceits of the persuasive engineer, and the intimacy between the two professions is now so cordial that one is apt to identify the Royal Institute of British Architects in Conduit Street with the Institution of Civil Engineers in Great George Street; indeed, the amalgamation is becoming more firmly consolidated, or cemented, every day, and we must, I suppose, regard it as the inevitable sequence to that steady advance in scientific construction that I have ventured to draw your attention to this evening. Is it not, I would ask, the result of those "actual necessities" that have arisen from ultra-commercialism and overcrowding? And so long as these remain the dominant features of our social conditions the investigation of the engineer's anatomy will be retained as a subject on the pages of your curriculum. No doubt this is very flattering to the engineer. He has nothing to lose by the interest you take in his work. His susceptibilities and instincts of form and beauty are not likely to be weakened or destroyed by the coalition. But what of yours? A gasometer may be more expansive, but is it more impressive than the Roman Pantheon? The Tower Bridge may be "a joy for ever," but is it really more beautiful than Waterloo Bridge? Can any combination of engineering and pseudo-architecture rival the transparent candour of the Crystal Palace? The works of Palladio and his compeers are, indeed, "divine" when compared with those parodic efforts, exalted to the skies, at the corners of our streets.

You have been reminded of the utilitarian principles adopted by the builders of ancient Rome; how they threw aside the stone lintel and the wooden beam to make use of their natural cement for concrete vaults, that covered the space, without thrust, like a metallic lid. Well, we have improved on the Romans in the manufacture of metallic lids and iron grids, but whether these are destined to survive the decay of our civilisation is a question that need not concern us; it is of greater importance to know that utilitarian architecture is not necessarily opposed to art. The evidence of Roman greatness, as reflected in its architecture, is not to be sought for in the borrowed styles of Etruria or Greece, but in the native style of imperial days, "when beauty was in a great measure incidental, and not specially aimed at by the designer." This spirit led naturally and easily to the development of a style which at least had that beauty which fitness is supposed to bring with it. The motto of the Roman architect was merely, "Build in truth." No question arose in his mind as to whether "agreement in the principles of architectural design was possible," or whether "the system of architectural education was ideal." These were settled for him by the principles of authority and continuity. By the principle of authority we mean that recognised standard which enabled the profession as a whole to agree about the truth; and by the principle of continuity we mean the tradition by which this standard was carried on, and modified or expanded to suit the wants of the time.

It is evident, after the lapse of hundreds of years and after many attempts, we cannot successfully resume the thread of tradition; and even the principle of authority—according to our definition—seems beyond reach, in view of the complexities of modern requirements and the duplicity that permeates our methods. What the future has in store it is impossible to say, and it is well we do not know. But if growth is the law of art, as of every kind of life, then undoubtedly there will come a time when architecture will be entirely free from those archæological entanglements that now retard its progress. As the Romans threw aside the lintel, so are we throwing aside the arch, and time alone can show whether, like our great progenitors, we shall be able to evolve an unaffected yet expressive style of architecture. But if ever again there is to be a prevailing style—assuming this to be desirable—there must of course be a general compliance to established methods and rules. In the meantime the efforts of those whose ideal is a universal system of training for the architect in this country should be acknowledged with gratitude by all who desire the advancement of architecture. What that system should include and what it should reject are questions that could not have arisen a century or two ago; now they are both wide and deep, and cannot properly be discussed here. Indeed, I fear I have already incurred the displeasure of your Council, and I await their vote of censure with "fear and trembling." May I therefore hasten to remind you that your first duty

* A paper read by Mr. J. A. Marshall, at the last meeting of the Architectural Association.

Digitized by Google

as students of this Association is unquestionable submission to the course of study laid down for you by your advisers?

"What you best can understand,
Is just the thing that's near'st to hand."

Goethe.

You need not fear that obedience to rules and methods will check the artistic impulse or the latent genius, any more than it did in the past. Salutary restraint in art is not opposed to originality. As Ruskin has said:—"A man who has the gift will take up any style going that is the style of his day, and will work in that and be great in that, and make everything that he does in it look as fresh as if every thought of it had just come down from heaven." When Ruskin wrote, modern architecture was—to him—in a hopeless condition, and he was oppressed by the futility of preaching a doctrine of celestial excellence in view of the want of that obedience, unity and order without which the architecture of the past would have been impossible.

Your hope to-day, then, should be that these conditions will be re-established in your profession, on a basis favourable to that art with which sublimity and beauty are peculiarly associated. These it was that ensured the transcendency of Hellenic art, the majesty of imperial Rome, the glowing wonders of Byzantium.

Mr. H. Home proposed a vote of thanks to Mr. Marshall for his paper, and wished, as a constructional engineer, to be permitted to make a few remarks upon some of the points raised by it. Four or five years ago he was asked to design a steel bridge; it was specially arranged that it should be of steel, and he was told that when the bridge had been designed and constructed an architect would be employed to make it beautiful. The architect was supposed to have accomplished this by hanging little stones all over the bridge, thereby adding sixty tons of extra material to be carried by the main girders. In another instance a ferro-concrete roof, admirably designed in every way, was used on a building supported by buttresses which would have served in any Gothic cathedral. As an engineer, he would not have employed the buttresses. In commenting on the use of ferro-concrete, Mr. Marshall had brought an accusation against the engineering profession, and yet the extensive use of the material was a question in which all constructors were very much interested. He (the speaker) had had an opportunity of examining a number of the old buildings of the world, and it had struck him that the designers and builders of early times seized on any material which would simplify construction. He contended, therefore, that if the builders of those days had had a material like ferro-concrete at their disposal they would have employed it. Then, too, in judging of engineers' works there must be discrimination between those of a monumental character and those which were only temporary, for the two could not be judged by the same standard of quality. In the carrying through of important schemes the speaker held the opinion that the engineer of to-day showed as much imaginative power and skill as the men of any age.

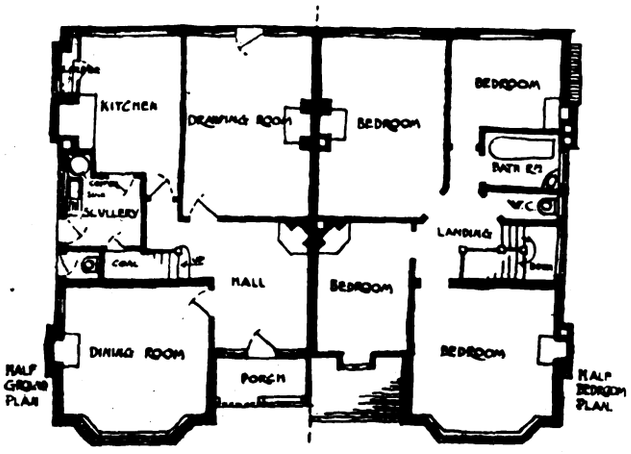
Mr. Gerald C. Horsley seconded the vote of thanks. Mr. Marshall, he said, made an appeal for honest architectural construction, and hoped the future would bring with it that almost universal artistic sense which the world once had. They could the more understand Mr. Marshall's views when they remembered his connection with the cathedral in Westminster, which they all so greatly admired. While, however, the speaker sympathised with the author of the paper, he could not follow him in the remarks he made upon the assistance an engineer could give an architect in his work, nor could he (the speaker) see why the use of steel should be objected to in buildings. They frequently used brick, and both brick and steel were manufactured materials. If steel were used in a building the architect should have some knowledge of the material he was handling, otherwise the architectural quality of the building would suffer. So long as architects understood the limits and possibilities of steel in any particular case, consultation with an engineer and assistance from him was of the utmost value. An alliance of that kind had certainly produced some fine work in France, such, for instance, as the new Lyons railway station on the Quai d'Orsay in Paris. With regard to reinforced concrete construction, the whole method was so much in its early days that its capabilities were hardly known. He did not see why an artist should not be able to make use of the new method; it might lead, by the wide spans which were possible in it, to some extraordinary developments in planning. He believed the architect of the Post Office building to which Mr. Marshall referred had said that architects using that form of construction should make their own drawings themselves, instead of handing sketch plans to the engineer of the particular patented process it was proposed to use. The speaker did not see how it was possible to design unless that was done, and after all there was no mystery in the different systems; the principle of the processes could be mastered in a short time. But designing in ferro-concrete was in its infancy, and as it was a very hard material to cut into or make alteration in once built, it was hardly likely to be widely used for private houses or in buildings likely to need alterations in the future. There was certainly one advantage the material had given us; it had made it clear that steel embedded in Portland cement was practically indestructible. All steelwork in future building should be embedded therefore in Portland cement. Passing on to the second part of the paper, the speaker said he thought we were apt, in our admiration of the magnificent qualities of mediæval architecture, to over-admire its constructional virtues. We did not know how much real statical knowledge was abroad at that time, but we did know that most of it was the result of experiment from the time the first dome of Justinian's church fell to the collapse at Beauvais and later still. It was not till we got to the time of Sir Christopher Wren that we found building based upon more certain knowledge. Sir Christopher had, too, a shrewd opinion of some of the mediæval methods of construction, as might be seen in his reports upon old St. Paul's, Salisbury Cathedral, and Westminster Abbey. In conclusion, Mr. Horsley said their chief hope for designing in beauty and building in truth was in education—the education both of themselves as artists determined not to scorn science but to learn from it, and also of the public, and thus to arrive at a general appreciation and consensus of opinion in art.

Mr. J. H. Markham suggested that even if architects could not spare the time to go very thoroughly into the scientific methods of reinforced concrete construction, it was essential they should have a rough notion of the principles; and when it came to making actual calculations for the carrying out of such construction the architect very rightly handed over that part of the work to the engineer.

Mr. Edwin Gunn and Mr. J. H. Elder Duncan also spoke.

Mr. Marshall, in his reply, said the object of his paper had been to remind the student that it was the duty of the architect to meet the wants of the hour without prevarication, while maintaining as far as possible the privilege of the artist, which was not, he believed, claimed by the engineer. The styles of the past had perhaps seen their day and nobly fulfilled their use, but they still had many lessons for the architect. It might happen that the ferruginous method of construction would eventually lead them back to that path of architectural rectitude which they seemed to have missed and the new material become invested with a sublimity and beauty hitherto undreamt of. Receding frontages rising tier above tier, with hanging gardens against backgrounds of gleaming faïence, would be an improvement on the sky-scraper that cast its gloom over cities.

A Meeting was held in the Jerusalem Chamber of Westminster Abbey on the 25th ult. for the purpose of furthering the movement for placing a John Bunyan memorial window in the Abbey. The window, which is being executed by Mr. J. M. Comper, will be a large one, and it is proposed to place it in a prominent position, with two main openings, each measuring about 20 feet by 6 feet, containing scenes from "The Pilgrim's Progress." The estimated cost is 1,400*l.*



The Annual Report of the Derbyshire Archæological Society alludes to a suggestion that the remainder of the Brough exploration fund be utilised for excavations at Peak Castle, Castleton. It is considered that the work, if done under careful supervision, would probably result in discoveries of great interest, but that it is so greatly important that it cannot be undertaken lightly. Members of the Society undertake to keep the Council informed of any discoveries of interest or of any contemplated acts of destruction or alteration to ancient buildings in the county. The report adds:—"Great acts of vandalism are now fortunately rare, and when they occur they usually come to our knowledge; but there are constant little alterations and additions being made to our old buildings, particularly the churches, of no great importance in themselves, but through which their features of interest gradually disappear, and these we often do not hear about until it is too late to interfere."

HOUSES AT THE HAMPSTEAD GARDEN SUBURB.

THE erection of these two houses has just been completed in "Hampstead Way," a main street through the suburb. They are opposite the houses illustrated in this paper on August 14 of last year by the same architect. The accommodation, as will be seen from the plan, consists of two sitting-rooms and a good hall with a fireplace, and all the usual offices have been provided. On the first floor there are four bedrooms (each with a

fireplace), a bathroom and w.c. The roof and chimney offsets are of dark red tiles, contrasting well with the white rough-cast walls. The chimneys are faced with red brick, and part of the bay windows is decorated with a simple design stamped in plaster.

Mr. BRETZFELDER, of Hampstead, has built these houses from the designs of the architect, Mr. J. GORDON ALLEN, of Dashmonden, Holmdale Road, West Hampstead, N.W.

STORAGE OF RAW RIVER WATER.

AT the meeting of the Metropolitan Water Board on Friday of last week the third report on research work by Dr. A. C. Houston, Director of Water Examinations to the Board, on "The Storage of Raw River Water antecedent to Filtration," was considered. This storage has been up to the present generally recommended for the raw water as obtained from sources of the metropolitan water-supply.

The work of the water examination staff of the Metropolitan Water Board has been largely devoted to investigating the matter anew, in the light of recent knowledge and with special attention to those tests which gauge the viability of excremental bacteria in water, note at the same time being taken of considerations previously neglected or assigned a position of subordinate importance.

A practical outcome of the above work has been that dependence is now being placed more and more on experimental proof that the water reaching the filter-beds is, as the result of adequate storage, in a reasonably "safe" condition antecedent to filtration. When the stored water results are satisfactory, this really constitutes a new and important element in the "safety" of the London water-supply. It means, indeed, that even if a breakdown in the filtering arrangements occurred, the quality of the water distributed to consumers, although possibly open to criticism on physical grounds, might yet be relatively (if not absolutely) innocuous.

Before proceeding to consider the results obtained in this investigation it is desirable to deal with a matter which, like mere physical sedimentation, is apt to allow of misconception.

The biological benefits accruing from storage of water are due to vital reactions rather than to mechanical effects. But it must not be assumed, as is commonly believed, that the death of pathogenic bacteria in water under storage is due solely to the antagonistic action of other and harmless bacteria. It has been found, indeed, that if a water be deprived, by filtration through a Pasteur filter, of all its bacteria and then inoculated artificially with typhoid bacilli, the typhoid bacilli perish as inevitably (although possibly less quickly) as if the water had not by filtration been robbed of, among other things, its normal bacterial flora. In other words, the death of pathogenic bacteria can take place in a water deprived of all particulate matter, living and dead.

Digitized by Google

The question to which Dr. Houston especially addressed himself in the investigation now to be recorded was:—Are the results of storage of water, as at present practised by the Water Board, of a sort to encourage a project of storage of all river water before submitting it to filtration? The degree to which storage has been (nominally) maintained varied widely at the several works of the Board, and thus arise many interesting considerations of a comparative sort. But in the first instance there was less concern with the relative merits of greater and less duration of storage than with definite advantage that might appear to have been gained from a reasonable degree of storage, the object being to ascertain whether the number of days storage capacity which it is necessary to provide in avoidance of shortage of water service under conditions most unfavourable, as regards weather and state of the river, may be held to suffice in the matter of satisfactorily securing safety of the water in an epidemiological sense.

The report then gives the bacteriological and the chemical results, and then treats of the shape, size, depth, construction and method of working storage reservoirs.

This is largely, says Dr. Houston, an engineering problem, and it is not proposed to trespass on debatable ground. It is necessary, however, in this connection to point out one or two matters which are of importance from the point of view of quality of water.

It is important that the inlets and outlets of the reservoirs should be so arranged as to permit of as complete a circulation of water as possible. If this matter is not attended to, part of the water reaching the filter-beds may have travelled by surface currents from inlet to outlet without practically any storage, while another part may have been stored for a length of time quite unnecessary for the purposes of safety. Over-stored water, too, may dilute and mask the bad quality of under-stored water, and this without destroying its potentially dangerous qualities. A storage reservoir in which the circulation of water is imperfect is economically a failure so far as the purification of water is concerned, and conditions of stagnation may operate in encouraging growths of algæ. It is probable that the "continuous flow" method is better than the "quiescent" method of working storage reservoirs, and that it is better to have a series of small reservoirs rather than one large reservoir. There might be advantage in causing the raw river water to pass first through a small settling reservoir before entering the storage reservoir proper. This would keep a good deal of the grosser and heavier suspended solids out of the main reservoirs and such a small reservoir could be cleaned out comparatively easily when occasion arose. The relation of the inlets and outlets of reservoirs to prevalent winds may also be of importance. These, however, are matters which may be open to dispute, and the point upon which stress is laid is that the circulation of water in the storage reservoirs should be rendered as complete as is reasonably practicable.

At the very end of this report the difficult question is considered of whether the storage of raw river water should be fixed on a maximum or on a minimum basis. If the Board elect to store raw river water on a minimum basis of thirty days' storage, it would be necessary to build reservoirs capable of holding far more than thirty days' supply of water, the reason being that sometimes, owing to conditions of floods or drought, the storage reservoirs are receiving little or no river water to make up for the water which is being daily abstracted from them for waterworks purposes.

On the other hand, if the Board decide to store water on a maximum basis of thirty days' storage, this means that occasionally the storage will fall short, it may be far short, of thirty days.

The former method means the construction of enormous reservoirs at an unremunerative cost, inasmuch as the storage would have to be unnecessarily prolonged under ordinary conditions in order to provide thirty days' storage under exceptional circumstances. The latter method would result in deterioration in the quality of the stored water during periods of stress and storm.

It is possible that the disadvantages of the latter method might be overcome in the following way:—

Mechanical filters or "roughing" filters or precipitation tanks might be interposed as a middle process between storage and sand filtration, and used only when the stored water results were unsatisfactory. As a matter of fact this process has been used (Puech's "roughing" filters) for many years in connection with the East London (Sunbury) Works. Or, either as an alternative or in combination with the above, the same processes might be employed antecedent to storage whenever the raw river water results were specially unsatisfactory.

I do not bring forward these suggestions in an egineering sense. Nevertheless, if the number of days of storage of raw river water is to be based on a maximum figure, they appear to me to be the only means of securing uniformly good results under all conditions of weather and state of river. During periods of drought it is obviously impossible to avoid temporary loss of volume of stored water. But when the volume of water in the river again allows of water being used for replenishing the storage reservoirs, its quality could be enormously improved by suitable means. Conversely, during periods of flood the intakes need never, or hardly ever, be closed if temporary expedients could be devised to render the water reasonably satisfactory for storage purposes.

If these tentative suggestions are practicable, the water in storage reservoirs could always be maintained at top water-level, except during periods of drought; and in times of flood succeeding drought, the water capacity content of the reservoirs could be restored without seriously fouling the water still remaining in the reservoirs.

Alternative Measures.

It is desirable to consider very briefly measures for the improvement of London's water-supply that may be regarded as alternative to storage.

It must be premised, however:—(1) That for crude purposes of quantity of water London must possess a huge reserve of storage capacity; (2) that the water must be filtered, even if it were proposed on biological grounds to resort to sterilisation processes of treatment; (3) that the London water-supply has been taken over by the Water Board as a going concern, with all the machinery and waterworks plant pertaining to the old régime.

On biological grounds the only possible alternative to storage would, it seems to me, be sterilisation. As regards sterilisation, perhaps no one in this country has been so favoured as I myself have been with opportunities of studying the subject practically. Thus I have had prolonged experience of the sterilisation of sewage effluents, in the first place with the Royal Commission on Sewage Disposal, and secondly with the Water Board. I have also, in conjunction with Dr. McGowan, faced the responsibility at Lincoln of sterilising the water-supply of over 50,000 people during a prolonged period. No one could be more sympathetic to projects of sterilisation or more favourable to its adoption, in particular and suitable cases, than I am, but in the case of London it is necessary to deal with existing facts and conditions, which militate against its adoption.

Having regard to the necessity of storage (for purposes of quantity apart altogether from questions of quality), to filtration in utilisation of existing plant and to the epidemiological history of the metropolis, the wholesale sterilisation of London water appears to me, on available evidence, economically out of question and therefore impracticable.

Disadvantages of Storage.

It is desirable that this aspect of the question should receive in this report, as in previous reports, full consideration.

1. The serious expense of constructing huge reservoirs is worthy of the closest consideration. But the cost of storage for "purposes of quality" is not to be estimated on the total expenditure involved, but only on that part of it which may be found to be in excess of that storage which is necessary for "purposes of quantity."

2. Excepting part of the New River and East London supplies, nearly all the raw water has to be pumped into the storage reservoirs. That is, the great bulk of the river water does not flow by gravitation into the storage reservoirs, but has to be raised into them. In so far as gravitation is not available for impounding purposes, acceptance of the principle of "active storage," as opposed to "passive storage," necessarily involves increased expenditure in coal and in general pumping charges.

3. Although it would be wrong to infer that storage often, or habitually or necessarily, creates conditions inimical to filtration, there is inevitable danger that prolonged storage, especially if the water remains stagnant, may lead, seasonally or occasionally, to the abnormal and abundant development of vegetable growths—materials harmless in themselves, but resulting in the deterioration of the water as judged by chemical and physical standards and causative of practical difficulties with its filtration. In this connection it is impossible to forecast the future or to offer any assurance that trouble will not arise in the future from this cause. On the other hand, there is the

Digitized by Google

gratifying fact that usually the use of stored water prolongs the life of filters to a remarkable extent.

4. Another plea commonly advanced against the habitual use of stored water is that when the river water is bright and clear there is no disadvantage, possibly even an advantage, in preferring it for filtration purposes. It is true that during a considerable part of the year, when the meteorological conditions are favourable, the river water improves very considerably in quality as judged by most, if not all, the ordinary analytical tests. It may also be the case that river water may sometimes be more amenable to filtration than stored water. It is true, too, that sand filtration is normally so effective a method of purifying water that the effluent from filters dealing with raw river water may sometimes be apparently as good as (possibly in some respects even better than) the effluent from filters dealing with stored water. This ability of sand filters to bring unfiltered waters of quite different character on to the same plane of apparent purity as the result of the filtration process is apt to create the impression that the quality of the water to be filtered is a matter of indifference. This view is undoubtedly unsound, though it is not easy to controvert it in a convincing manner. For example, one filter might be dealing with raw river water containing 100 B. coli per c.c., and another filter with the same water which, as the result of storage, contained only 1 B. coli per 100 c.c. of water. The filtration process would easily bring the raw river water to apparently the same condition as the stored water before filtration, whereas the stored water, being already so pure, could hardly be rendered much purer by the filtration process. Yet from the biological point of view there can be no question which would be the safer water to drink. I would not seek in the least to minimise the value of filtration in tending to make unequal things equal, or apparently equal, but this should not lead to too easy faith in filtration irrespective of the quality of the water to be filtered. It needs to be remembered that the chief source of pollution of river water is sewage, that the dangerous element in sewage is excremental matter, and that the amount of excremental matter discharged into the sewers from a given population does not vary with the seasons, although heavy rainfall influences greatly the amount of surface and subsoil water which also reaches the sewers. It is not, indeed, contended that dry weather may not materially diminish the impurities actually reaching a river. Nevertheless it is most desirable to keep in view this never varying contribution to sewage of human excremental matter, much of which finally reaches the river in an imperfectly purified condition. Considerations such as the above, coupled with the results of the routine examination of the river water, inevitably suggest doubt whether the raw waters, even during the best months of the year, are sufficiently free from impurities to be filtered without antecedent storage. If it be admitted that the raw water is never wholly free from undesirable bacteria, which become largely, if not entirely, eliminated in the process of storage, and further that sand filters do no more than afford a relatively, not an absolutely, effective barrier to the passage through them of these microbes, it is obvious that the filtration of adequately stored water cannot be attended with the same risks as the filtration of raw river water. That it may be difficult, or even impossible, directly to prove the full benefit of storage in this connection does not destroy the validity of the pleas in favour of using stored water for filtration purposes.

5. An objection which may be legitimately cited against the continuous circulation of river water through storage reservoirs is that it inevitably leads to a gradual accumulation of mud at the bottom of the reservoirs. This is a matter which deserves consideration in the future, because the fermentation of this accumulated mud is apt to cause some deterioration in the quality of the supernatant water. Of course, the smaller reservoirs can be cleaned out periodically, but this involves considerable expense. It may be practicable, as suggested elsewhere in this report, that raw river water, instead of being passed directly into the large storage reservoirs, might first be allowed to undergo some settlement in a reservoir small enough to allow of its being cleaned out occasionally without serious difficulty or expense. Alternatively, the great bulk of the suspended matter in the raw river water could be largely removed, antecedent to storage, by "roughing" filters or by precipitation tanks, but the cost of this as a routine measure would be serious. As a means of partially purifying specially impure river water, which otherwise might be considered too impure to be impounded, such a project is, however, worthy of consideration.

6. A possible disadvantage of using stored water is that the "blanket" or "skin," which forms on the surface of the sand in the filter-beds, may not prove so effective a bacterial filter as that resulting from the use of raw river water. There may be an element of truth in such a contention; but it is certain that sometimes the "stored water skin" errs on the side of being too impervious, and it is obvious that it is much less important to have a microbe-tight blanket when using comparatively safe stored water than when using potentially dangerous raw river water. Subject to absence of abnormal development of algæ, there can be little question which kind of water engineers would prefer to use year in and year out; and there can be no question from the bacteriological point of view that preference should be given to the stored water. Further, it needs to be noted that the blanket formed on sand filters is not solely a passive accumulation of dead particulate matter derived from the water "feeding" the filters. It is an "active" skin in that it is a mixture of living and dead suspended matter, built up not only from the "feeding" water per se, but from developmental changes occurring in this water as it lies on the top of the sand and also doubtless in the skin itself. My experience since 1905 of the quality of filtered water supplied to East London from the East London (Clapton) Works, which deals, after prolonged storage, with the initially unsatisfactory Lee River water, does not lead me to think that this question of "stored water skin" versus "raw water skin" need necessarily be of vital importance.

To sum up, it is desirable to point out that most, if not all, of the real or assumed disadvantages of storage disappear if the use of stored water is regarded, not as an unalterable law of the Medes and Persians, but an elastic policy which can be departed from on occasions when the local conditions render this feasible and at the same time desirable.

Advantages of Storage.

In the following few sentences endeavour has been made to condense the chief points in favour of the storage of raw river water:—

1. Storage reduces the number of bacteria of all sorts.
2. Storage reduces the number of bacteria capable of growing on agar at blood heat.
3. Storage reduces the number of bacteria capable of growing in a bile-salt medium at blood heat, chiefly excremental bacteria.
4. Storage reduces the number of coli-like microbes.
5. Storage reduces the number of typical B. coli.
6. Storage alters certain bacteriological river water ratios; for example, it reduces the number of typical B. coli to a proportionately greater extent than it reduces the number of bacteria of all sorts.
7. Storage, if sufficiently prolonged, devitalises the microbes of water-borne disease (e.g. the typhoid bacillus and the cholera vibrio).
8. Storage reduces the amount of suspended matter.
9. Storage reduces the amount of colour.
10. Storage reduces the amount of ammoniacal nitrogen.
11. Storage reduces the amount of oxygen absorbed from permanganate.
12. Storage usually reduces the hardness and may reduce (or alter the quality of) the albuminoid nitrogen (see text).
13. Storage alters certain chemical river water ratios; for example, the colour results improve more than the results yielded by the permanganate test.
14. Storage has a marked "levelling" effect on the totality of water delivered to the filter-beds.
15. Storage tends generally to lengthen the life of the filters. (Only under exceptional conditions is the converse true.)
16. An adequately stored water is to be regarded as a "safe" water, and the "safety change" which has occurred in a stored water can be recognised by appropriate tests.
17. The use of stored water enables a constant check to be maintained on the safety of London's water antecedent to and irrespective of filtration.
18. The use of stored water goes far to wipe out the gravity of the charge that the chief sources of London's water-supply are from sewage-polluted rivers.
19. The use of adequately stored waters renders any accidental breakdown in the filtering arrangements much less serious than might otherwise be the case.
20. The habitual use of stored water would lighten the grave responsibilities of the Water Board as regards the safety of the London water-supply, and would tend to create

Digitized by Google

a sense of security amongst those who watch over the health of the Metropolis.

It will be remembered that in the introductory part of this report it was stated that the primary question to be solved was whether the stored water results were so greatly superior to the raw river results as to justify the policy of storing all river water before filtration. I venture to anticipate that it will be considered that this question has been answered satisfactorily in the affirmative.

The difficulty of answering the subordinate question as to the exact number of days that a water should be stored before filtration may be rendered easier if certain assumptions are entertained. These are:—

1. That the principle of "active storage" as opposed to "passive storage" is accepted as sound.

2. That it is possible to "pool" the existing stored-water interests, so as to remove the anomaly of using over-stored water for some districts and under-stored water for others.

3. That the river water can be effectively and continuously circulated throughout the several storage reservoirs.

These assumptions being granted and bearing in mind that the Board's existing storage reservoirs are now capable (in the aggregate) of holding about forty times the average daily supply, it is considered that, subject to one qualification, the present storage capacity (say, thirty days) is reasonably sufficient (on the present consumption of water) for purposes of safety. The qualification is that sometimes no river water can be used to replenish the storage reservoirs for the reason that the rivers are in high flood and in too unsatisfactory a condition to permit these waters to be impounded, or because, owing to drought, there is too little water in the rivers to allow of its being abstracted for water-works purposes. In these untoward circumstances the water in the storage reservoirs must needs sink lower and lower each day, with the result that when the conditions again admit of refilling them (possibly with water of an inferior quality), a period inevitably follows during which the duration of storage of necessity falls short, it may be far short, of thirty days.

There are two ways of coping with this difficulty:—

1. To consider thirty days as a minimum period of storage. This would entail the construction of huge reservoirs at an unremunerative cost, capable of holding far more than thirty days' supply of water, in order to cope with the emergency conditions just mentioned.

2. To consider thirty days a maximum period of storage, but to adopt during times of stress and storm some such additional methods of purification, antecedent to storage or subsequent to storage, but antecedent to final sand filtration, as has already been briefly outlined.

My final conclusion is that raw river water should be stored antecedent to filtration, preferably for thirty days. The question of whether the thirty days' storage should be fixed on a maximum or on a minimum basis must be left unanswered, but if the former alternative be chosen, the desirability of employing supplementary processes of water purification to tide over emergencies is worthy of consideration.

THE OUSE BRIDGE CHAPEL AT YORK.

DR. EVELYN recently gave two lectures before members of the Yorkshire Archæological and Architectural Society. On the earlier occasion Dr. Evelyn's subject was "The Old Ouse Bridge and Her Burden," and on the last he spoke of "St. William's Chapel"—one of those burdens.

Dr. Evelyn endeavoured to prove approximately the date of the erection of the St. William's Chapel by historical data and by architectural detail shown in drawings by Halfpenny and Cave, the two great York topographical artists of 100 years ago. Some said it was built in memory of the miracle performed by St. William in 1154, when the then wooden bridge was broken down by a crowd which followed him and none were drowned. (This bridge was rebuilt and stood until, in 1564, the two central arches were washed away by a flood.) Others maintained the original bridge was built as an atonement by the citizens after a conflict in 1268 with John Comyns, a Scotch laird, several of whose followers were killed; others, again, that it was built in 1154 and added to in 1268. The second contention he hoped to get deleted, as false, from the history of York. It was that after the "row" the citizens were made to pay 300*l.* and to build the chapel, for which they were to find two priests to pray for the souls of the slain Scots for ever. Drake, Cæsar, Caine, Halfpenny, Cave, and Hargrove followed this idea, and Dr. Solloway, as recently as 1905, gave four reasons why the chapel could not have been built before 1235. He (Dr. Evelyn) had documentary evidence which a friend had given him casually when he asked for "anything fresh" bearing upon the subject. His friend fetched it, as an afterthought, from a corner of an old drawer. It was written in Latin 650 years ago; the ink was good and clear and beautifully legible. The translation of the document is as follows:—

To all the faithful in Christ who shall see this writing. Roger de Holgate, near York, eternal greeting in the Lord. Let all men know that I with the counsel and good wish of Agnes, my wife, and Abel, my son and heir, and Robert, my son, both for the safety of my soul and those of my ancestors, and for a certain sum of money given, granted, and by this my present letter confirmed, for the sustentation of the service of the blessed Virgin Mary in the Chapel of the blessed William upon Ousebridge, an annual Rent of 2*s.* in that land with its appurtenances in Micklegate, which stretches in breadth to the land of Hugo Cady on one part and the land of Nicholas Maysand on the other and in length from the Royal-street of Micklegate in front as far as the Nuns of St. Clement behind.

To have and receive the aforesaid rent of 2*s.* for the aforesaid chapel for the sustentation of the aforesaid service of the blessed Mary in the same chapel at 2 annual terms in equal parts namely, 12*d.* at Pentecost, and 12*d.* at the feast of St. Martin in the winter, from the aforesaid land for ever.

And me the aforesaid Roger and Agnes, my wife, and Abel and Robert, my sons, warrant acquit and defend for ever against all men the aforesaid rent of 2*s.* for the sustentation of the service of the glorious Virgin in the aforesaid Chapel by the money given into our hands and for the safety of our souls and those of our ancestors.

And our heirs and assigns are held to warrant and defend the aforesaid rent for ever.

In witness of which thing I have placed to this present writing for me and mine my seal so that the aforesaid rent shall be received by William de Acum and Stephen Bland, then the custodians of the aforesaid Chapel, and by any of their successors at the aforesaid terms.

Then witness John de Seleby (then Lord Mayor), J. Blend, J. de Conyngston, Henry le (?Sezevaux), Serton de S., Andrew de Seleby, Stephen Wylet, Stephen Bury, Alan Simpson, and others.

John de Seleby held office in 1252-63, and even if the document was written in the latter year, it proved the chapel was there five years before the "row" in 1268. It was interesting to see "Holgate" thus spelt in view of statements that it used to be "Holdgate." His second bit of evidence was from the Patent Rolls of 1228, in which Henry III. granted protection to "David the Almsgatherer of the Bridge of Ouse and of the Chapel of St. William of York." This was forty years before the "row." Again, in 1223, Bishop Honorius III. wrote a protecting letter to "Our beloved son B; rector of the Chapel on Ouse Bridge." This was forty-five years before. He was inclined to believe the chapel was built shortly after the fall of the wooden bridge in 1154, and was dedicated to St. William in gratitude.

Bridge chapels, Dr. Evelyn explained, were built as supports or staithes for strengthening the bridge; as residences of one or more priests, who usually lived in the crypts, while they also collected alms from passengers for the upkeep of the bridge; or for religious and charitable purposes, the building of a bridge and chapel being regarded as an act of the greatest piety. They were also intended for the guidance and direction, and probably for the security and refreshment, of benighted travellers and navigators, and for that purpose a cresset or beacon was placed on the keeps or towers; a further purpose of their erection was as shrines for pilgrimages.

Dr. Evelyn went on to point out the evidence provided by the architectural styles to be observed in the drawings of the chapel, and showed many very beautiful sketches and pictures by various artists, particularly those by Cave and Halfpenny, but for whom the present generation would have had practically no detailed knowledge of the little chapel on the bridge. The lecturer spoke of the elegant chain moulding of the south door, tho late Norman arch being supported by early English columns. The chapel was 36 feet long by 28 feet wide, and had a wall arcade of rich design, the mouldings being distinctly late Norman (twelfth century), and being supported upon capitals he took to belong to the thirteenth century. There was one corner partitioned off, and he suggested this was to keep the records of the city in when the chapel was used as the council chamber. The Norman

Digitized by Google

window above the door had fourteenth-century insertions; so had that in the south-west aisle, and they found thirteenth-century east windows, to which period also belonged a narrow doorway through the wall arcade. The arches of the main arcade were twelfth century, and rested upon thirteenth-century pillars. The door in the wall arcade could scarcely have been made for the convenience of the merchants who once used the chapel as an exchange. In 1235 the bridge was extensively repaired, and he had no doubt the chapel was much re-edified at the same time. The thirteenth-century alterations were probably made just before the "row," so when it was ordered that, in atonement, a chapel was to be built on the site of the conflict, the authorities, being in a bit of a fix because there was a chapel there already, only had to build a chantry at the west end and make a doorway through the screen to it. Thus it seemed the west end of the chapel was of later date than the other part. There were three bells and a clock in the tower, and in 1593 it was directed that one bell should be rung at 4 and 5 A.M. and at 6 and 8 P.M.—a forerunner of the new Daylight Saving Bill. St. William's was not only a chantry, but also a "free" chapel, and was called the "King's free chapel upon Ouse Bridge." In 1545 it shared the fate of the other religious houses in the city and was suppressed. From that date till its demolition in 1810, it served many and varying purposes. In 1555 it was converted into a school by Robert Morris, chaplain, who was permitted to use "the great chamber, or chapel, on Ouse Bridge for his skole to teach children in." Subsequently it became the exchange for the merchants of the city, a record office, and the chamber of the Common Council, while the crypt was adapted as a "kidcote," or prison for felons.

GENERAL.

The Duke of Norfolk, Lord Lieutenant of Sussex, has been nominated President of the Sussex Archæological Society. The membership of the Society is now 789.

Work is in Progress in connection with the strengthening of the western turrets of Salisbury Cathedral, a slight subsidence having recently been noticed. The defects are not of a serious nature.

Chelsea Old Church is to be repaired at a probable cost of 2,710*l.* if the necessary funds can be raised. The roof, the paving, the heating apparatus, are the principal things in need of attention. The work will be entrusted to Mr. W. D. Caröe, F.S.A.

Messrs. A. J. Gale & Son, owing to expiration of lease, have removed their offices from No. 20 to No. 35A Mecklenburgh Square, W.C.

Messrs. Rickman & Burr, surveyors, 8 Montague Street, Russell Square, W.C., have taken into partnership Mr. T. A. Burr (the son of Mr. E. J. Burr). The firm will retain its present title.

The Marylebone Borough Council propose to ask the President of the Royal Institute of British Architects to appoint a competent adviser to report on the suitability of certain sites for a new town hall in Marylebone, in lieu of the present inadequate municipal building.

The Competitive Designs of Messrs. Bigden & Walton, architects, Buxton, have been accepted for new Primitive Methodist chapel and schools in Market Street, Chapel-en-le-Frith. The estimated cost is about 2,000*l.*

Stoke-on-Trent Town Council are maturing a scheme for the extension of the present town hall at a probable cost of 20,000*l.* It is proposed to provide an adequate court-room, a small assembly-room to accommodate about 300 on the ground floor, a number of ante-rooms, and a large assembly-room, to seat at least 3,500 people, with reception-rooms, &c., on the same floor. A general competition will probably be organised for obtaining designs.

The Carnarvonshire Education Committee have received a communication from the Board of Education with reference to the committee's revised scheme in regard to the provision of new schools and the reconstruction and improvement of existing buildings during the year ending March 1910. In cases where improvements were deferred it was suggested that the committee should make some compensation for the delay by supplying a few good and attractive pictures to lighten the appearance of the old premises. The Board were informed that the walls of many of these schools were covered with antiquated and faded maps, and in some cases with even more disfiguring sheets.

A Frankfort Consular Report states that an association has been formed in Germany for the purpose of establishing a national chemical laboratory. A fund of 1,000,000 marks is to be raised for erecting a suitable building with the requisite equipment. The board of directors of the association is requesting the Federal Government to support the new institution by an annual grant of 100,000 marks. The State Government of Prussia has tendered a site for the building free of cost.

The Estimates for the Civil Services and Revenue Departments for 1909-10 have been issued. For the Civil Services the sum of 40,070,171*l.* is required, an increase of 7,981,728*l.* over the total for the past fiscal year. The principal cause of this is the provision of 8,750,000*l.* for old age pensions. The total sum required under Public Works and Buildings is 3,164,784*l.* The more important works for which provision is made include the erection of official residences for the First Lord of the Admiralty and the Senior Naval Lord, 29,000*l.*; the erection of Meteorological Offices, 5,000*l.*; the extension of the National Gallery, 19,000*l.*; works for the protection of the Gallery from fire, 8,500*l.*; and the erection of a Recruiting Station in Great Scotland Yard, 15,000*l.*; the extension of the Patent Office, 50,000*l.*; and the erection of additional Courts of Justice, 16,000*l.*; construction of a new Melting House at the Mint, 5,000*l.*; alterations for the protection from fire of the Sasines Office, General Register House, Edinburgh, 6,000*l.*; and adaptation of the old Royal Institution building at Edinburgh for the Royal Scottish Academy and other purposes, 5,000*l.*

The City Lands Committee have submitted to the Corporation a report on the moneys expended on the new Central Criminal Court. The building was begun in 1900 from designs prepared by the late Mr. E. W. Mountford, F.R.I.B.A., and completed and opened in the spring of 1907. The net cost, after allowing for 55,800*l.* received from the county rate and 701*l.* interest on the site, has been 332,831*l.*—viz., site, 40,000*l.*; temporary cells, 5,320*l.*; builders' contracts, 303,900*l.*; cost of architect's designs and fees, 22,959*l.*; furnishing, 11,764*l.*; insurance, 941*l.*; compensations and redemption, 4,446*l.* Thus 17,168*l.* of the authorised amount has been unexpended. The general upkeep of the building is at present annually 5,000*l.*, which will be exceeded in years when painting, renovation, &c., were required. The cost of the upkeep of the old building was 1,700*l.* a year.

A Public Meeting was held at the Assembly Rooms, Bath, on Saturday, for the purpose of taking steps to avert, if possible, the threatened destruction of the colonnade on one side of Bath Street. Prebendary Boyd, rector of Bath, presided, and the speakers included Professor A. Beresford Pite and Mr. D. S. Maccoll, LL.D. The following resolution was adopted:—"That this meeting of citizens and friends of Bath strongly condemns the proposed destruction of Bath Street, a unique and characteristic example of eighteenth-century architecture and an essential part of the Bath improvement scheme of 1789, and earnestly hopes that means may be devised to avert the threatened mischief." A copy of the resolution was ordered to be sent to the Mayor of Bath and to Mr. Waring, whose plans for the remodelling of the Grand Pump Room Hotel, which he proposes to reopen, involve the destruction of the north side of the street.

The Annual Report of the chief officer of the London Fire Brigade states that the total number of fires, excluding chimney fires, attended by the Brigade during 1908 was 3,238, this number being 82 less than in 1907. Of this total 61 were classed as "serious" and 33 occurred outside the County of London. Fire stations in course of erection and to be erected will be entirely motor stations, the experience gained with the motor appliances at present in use justifying the adoption of this course.

A New Carnegie Library situated in Great Brunswick Street, Dublin, is now nearing completion, and will shortly be handed over to the Corporation by the contractor, Mr. G. Langley. Some time ago Mr. Carnegie promised a sum of not less than 28,000*l.* to provide public libraries in Dublin. Of this sum 4,000*l.* was expended on the Charlemont Mall library, and about 10,000*l.* has been absorbed in the present contract, leaving a balance of 14,000*l.* unexpended. The frontage is 300 feet, with depth of 85 feet. The style selected is Georgian of the eighteenth century, of which some very fine specimens are to be found in Dublin. The materials adopted are Mountcharles sandstone, the strings, cornices, dressings, &c., being of Ballinasloe limestone. The design has been prepared by the city architect, Mr. C. J. MacCarthy.

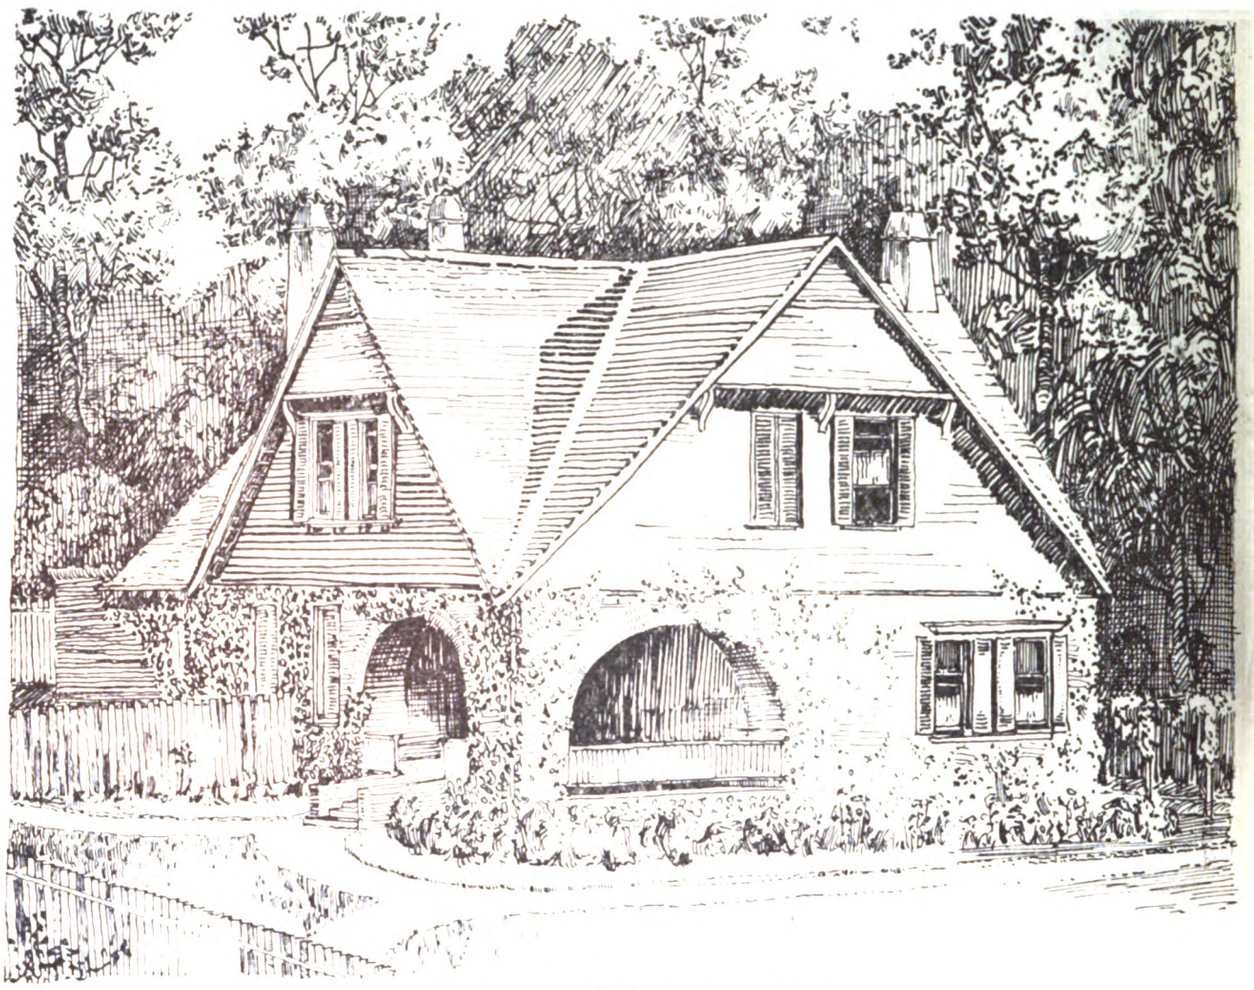
The Architect.

THE WEEK.

The compromise that has been accepted with virtual unanimity by both the registrationists and the educationalists in the Royal Institute of British Architects, and that formed the basis of the application for a new or supplemental charter, does not, of course, completely satisfy either party. A compromise never does. Now that the charter has been granted—though we are still waiting for the revised by-laws which will make that charter operative—the registrationists, within and without the Institute, are pushing on to a further effort, and have induced our esteemed contemporary, the *Builder*, to undertake a plébiscite of all architects in the kingdom on the question of registration. This is a step that certainly ought to have been taken by the Institute itself before it came to a conclusion as to the lines on which its constitution should be remodelled. The ruling spirits of the Institute profess to desire—what undoubtedly the majority of its members do wish—that it should represent the whole of the architectural profession, that it should occupy the position in architecture that the Institution of Civil Engineers and the Surveyors' Institution hold in the cognate professions. To obtain this position it should certainly ascertain, on all vital subjects, the feeling of the majority of the architects of the United Kingdom, and adopt their views. Failing action by the Institute, the *Builder*, as the oldest of the professional journals, is fully justified in conducting a plébiscite. The only pity is that this has not been done before the new charter was requested. We trust that this tardiness will not influence any of our readers to ignore the matter, but that they will record their opinion for or against registration.

The Council of the Royal Institute of British Architects would do well to follow the example of the Society of Ordained Surveyors (Edinburgh), from the accounts of whose General Examining Board we find that the amount of twelve guineas was paid in fees to the examiners who judged the work of nine candidates. The examination of students' papers is at the best wearisome and trying work, and entails to the conscientious examiner a great deal of responsibility, influencing, as it does in the case of qualifying professional examinations, the whole of a young man's future career. The number of candidates at the Institute examinations is now so large, and the bulk of work falling upon the examiners is so heavy and has to be got through with so much expedition, that it is only just to candidates and examiners alike that the latter should be paid for their services. We fully believe that the Institute examiners carry out their honorary labours as conscientiously as possible; but, however conscientious a man may be, he cannot help being biassed by the knowledge that he is doing irksome work for nothing, and there can be little doubt that candidates are prejudiced when they are being tested by unpaid examiners. The excuse we have heard made for non-payment of their examiners by the Royal Institute is that adequate reward is not financially possible. But is this a valid excuse? If half the fees paid by the candidates were ear-marked for the payment of an honorarium to each examiner, we know this would be quite appreciable and, we venture to think, appreciated.

The Architectural and Topographical Society and its Hon. Secretary, Mr. Wilfrid Travers, are to be congratulated on the excellence of No. 4 of *The Architectural and Topographical Record*, and particularly on the work of the Hon. Secretary for Ireland, Conchubhar ua Briain, better known to his English friends, and particularly the members of the A.A. Camera and Sketching Club, as Conor O'Brien. The subject of Mr. O'Brien's contribution is the parish of Askeaton, in the barony of Connello Lower, county Limerick, and the buildings thereof, very fully described and illustrated, are the parish church of St. Mary, the Franciscan convent, and Desmond Castle. These are interesting not solely archæologically but architecturally, and give us an admirable insight into the character of Irish Mediæval work. We are particularly struck with the similarity between the form of window-heads and sections of mouldings in the abbey and castle of Askeaton with those of examples at Leiria, in Portugal, and wonder if there is any causal connection. To admirers of the work of Mr. Voysey we commend a study of the chimney-piece in Askeaton Castle.



Besides Mr. O'Brien's admirable record, this number contains a description by Mr. Charles E. Lovell of the parish church of St. Mary Magdalene and Longfield Court, in the parish of Longfield, a typical North Kentish village, which, though affording less opportunity to the author, are equally well treated as the remains at Askeaton. The fragments of the screen formerly existing in the church are not only curious but suggestive. In fact, the Society well justifies its title. The records it is making are not merely topographical but also architectural.

We are informed by *The Times* (*Engineering Supplement*) that "two plans are in use for coating metallic pipes with a protecting surface of tar." One to make the pipes hot and plunge them into cold tar, the other to lower the cold pipes into hot tar. Now we understand why pipes that are sold as "Angus Smith treated" are so often unsatisfactory at the present day. The essential point of Dr. Angus Smith's process was that both pipe and tar (or bituminous composition) were each raised to a definite temperature, and it is too bad of *The Times* to ignore the method that has proved satisfactory and to leave it to be understood that there are only "two plans," both of which are inferior. It is careless statements like this that are responsible for the crystallisation, in the minds of young engineers and architects, of an immense amount of ignorance which it requires much future instruction and experience to dissolve and clear away, as was the case with the famous misprint of "black bullock's hair." Humour is often found in the most unlikely places. It is exquisite to be told that if the plan of heating the pipes and plunging them into cold tar is adopted, "there is a risk that they may become fissured." *Punch* has missed a gem this week.

The provinces are frequently more advanced and progressive than the metropolis, and Liverpool is one of the most go-ahead of our great cities, partly, no doubt, from the inherent energy of the Lancashire man, and partly from the intimate association of Liverpool's citizens with the hustlers of the United States. Hence we are not surprised to learn that in Liverpool there is installed a system of fire mains and hydrants from which an ample supply of water is delivered for the extinguishing of fires. The hydrants are fixed normally about 70 yards apart, but in some cases in the business portions of the city they are as close as 30 or 40 yards apart, so that often twenty or more hydrants can easily be concentrated on a fire. As each hydrant delivers from 8,000 to 10,000 gallons of water an hour, it will be gathered that there is an ample supply, and, as a matter of fact, the steam fire engines are needed in only a small proportion of the outbreaks of fire, hose from the hydrants being usually sufficient.

We congratulate the Crittall Manufacturing Company, who are well known to many of our readers, on the success of their libel action, and the justification thereby in the High Court of their policy with respect to trades unionism, a policy at once dignified and equitable. The company made no objection to any of their workmen joining a trade union if they wished, but firmly and successfully resisted any coercion of those who preferred to remain non-unionists. The dismissal of those who attempted coercion was followed by retaliation in the form of a circular which came within the scope of the law of libel. Hence the action in which the company was successful.

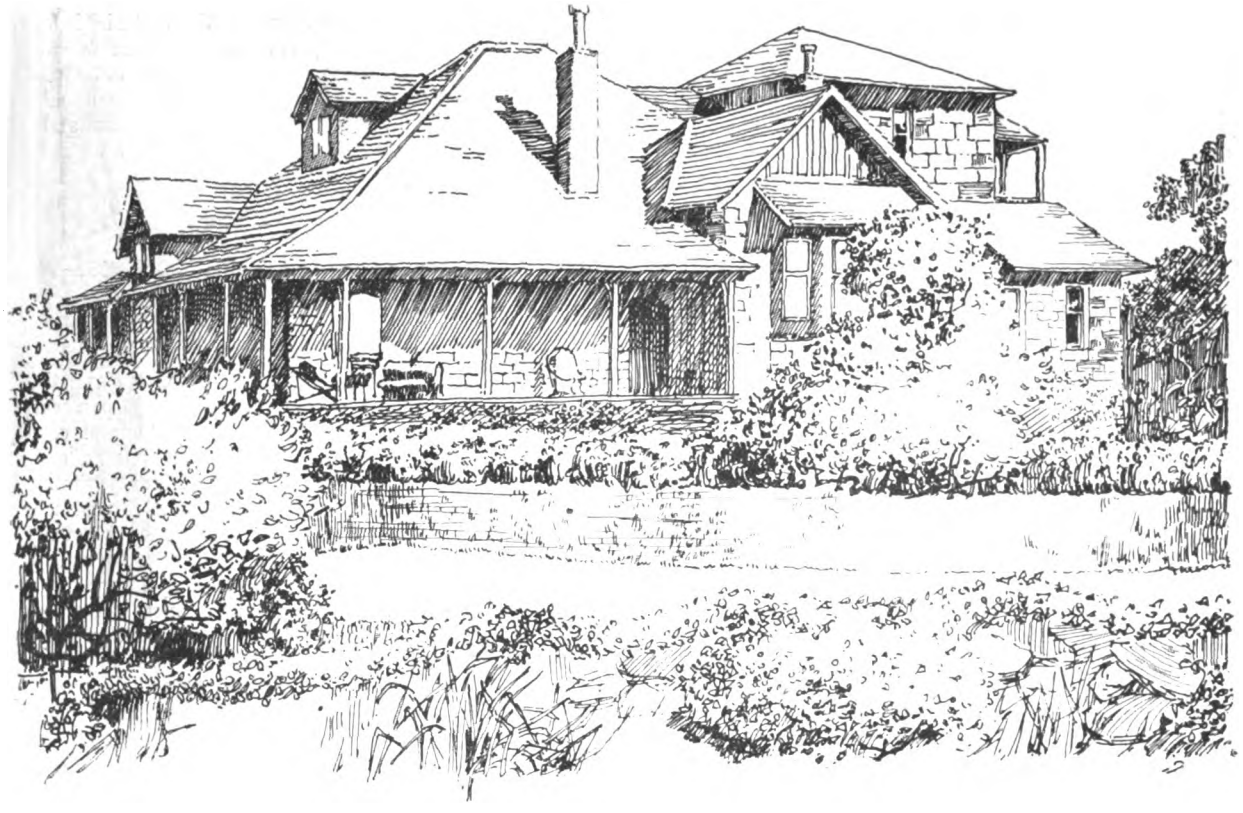
A HOUSE AT KILLARA, N.S.W.

AUSTRALIAN SUBURBAN ARCHITECTURE.

THE most distinctive architecture of Australia is to be found not in the great cities, where there is little differentiation from that in the various capitals of Europe, but in the smaller townships and suburbs that are, at present, cities in the making. The suburbs of the busy Australian capitals are frequently at a considerable distance and separated by open country, railway journeys of ten, twelve, or more miles being part of the daily life of large numbers of business men. Thus the advantages of purer air, gardens and shady trees are obtained, whilst the possibility of ample ground space for sites enables a considerable use to be made of one-storey planning. Indeed, one might say that the typical Australian suburban houses are one-storey buildings with plenty of verandahs, bungalows in fact. Not that the one-storey building is universal, far from it; examples of two-storey and even three-storey houses are not uncommon in the suburbs. The verandah, however, is almost an absolute necessity, for we must remember that the latitude of Melbourne is about the same as that of Lisbon, Seville and Palermo, and shade is a blessing for which to be grateful.



An insight into the character of the planning of Australian houses may be gathered from Mr. HADDON's book* on Australian architecture, and the examples illustrated therein are suggestive for the planning of bungalows, summer and week-end cottages in England. One feature that the author proposes is well worthy of consideration, the substitution of one large common or living room for the number of small reception rooms that has been a dominant element in our own suburban villas. The idea is not new nor peculiar to Australia, but has been largely adopted in summer cottages by the architects of the United States, where the large living room with a small "den" has for many years been quite the usual thing.

Mr. HADDON's plans range from the small workman's cottage, with living room, kitchen and three bedrooms on one floor, to the large country house on one or two storeys, with a full complement of reception rooms and many bedrooms. The planning of houses on one storey only is apt to tempt the designer into the use of long and dark corridors, and Mr. HADDON has in several instances fallen into temptation; indeed, his planning generally leaves much to be desired. Besides houses the author gives a few designs for business premises of various sorts, but these are mostly such as might be expected in a rising township or suburb, and the book is therefore more properly representative of the suburban or country architecture of Australia than of that of its capital cities or of Australian architecture as a whole. And we do not except the plans of a shearing shed and butter factory, for an Australian city usually starts from a pastoral or agricultural foundation, then becomes a village or "city" with one main street and irregularly placed bungalows or shanties, the thickly wooded masses of trees, mainly varieties of eucalyptus or "gums," being cleared for the purpose. In our plate the foreground tree in the top left-hand view is a "stringy bark" and that on the right a "blue gum," both varieties of eucalyptus. As the town grows the main street often becomes a boulevard, with shade trees planted on each side, for which purpose the Moreton Bay fig is frequently used, as in Prince Street, Grafton. Grafton is a fair example of a young Australian city, situated in a fertile district, forty-five miles from the coast, on the river Clarence, which is navigable as far as Grafton for vessels of considerable tonnage. Grafton, although at present a comparatively small town, is literally a city, according to our English definition, for it gives the title to the bishopric of Grafton and Armidale.

The views we give of typical Australian suburban houses are not taken from Mr. HADDON's book, but are sketched from photographs.

* *Australian Architecture.* A Technical Manual for all those engaged in Architectural and Building Work. By Robert J. Haddon, architect, Fellow of the Royal Institute of British Architects, Fellow of the Royal Victorian Institute of Architects, Fellow of the South Australian Institute of Architects. MARBLE.

WHEN an architect for the first time in his experience is in the fortunate position of being able to use marble for his building he is often placed in some difficulty. His knowledge of what marbles are on the market, their qualities and their appearance is perchance limited, and he is liable to make his selection on insufficient data, only to find when it is too late that there are other varieties that he would have preferred to those he has chosen. We are glad, therefore, to welcome the appearance of "a handbook for architects, sculptors, marble quarry owners and workers, and all engaged in the building and decorative industries."* The author says in his preface:—"No apology is needed for the introduction of the work. Marble is perhaps the least known of all the materials employed in a building. Its literature is scanty and not up-to-date, the manner of its selection for use is haphazard rather than methodical, and generally speaking there are few building materials or accessories respecting which knowledge is less readily obtainable." This is no longer strictly correct, for Mr. Renwick has in one volume given us all the literature that is needed, ample and thoroughly up-to-date, so that an architect who desires clear and full information on the subject of marble will here find all that he wishes.

Mr. Renwick does not split hairs in a pedantic manner as to what is or is not, strictly and scientifically speaking, marble, but includes under the term, as architects do generally, "any natural stone that is of less hardness than granite, having a sufficiently close texture to take and retain a polished face and being produced in such quantity as to be available for use for decorative purposes."

The manner in which marble is formed by Nature is well illustrated by the example of the well-known Hopton-Wood stone, the intrusion of volcanic or igneous rock into previously formed beds of limestone resulting in the metamorphosis of the limestone into marble. The widely varying circumstances under which the intrusive rocks have penetrated and the differences in composition of the original rocks before metamorphosis have been the cause of the numerous variations in the colour, composition and, above all, physical structure of marbles which lead the author to his classification into saccharoidal, unicoloured, variegated, fossiliferous, crinoidal, brecciated, laminated, travertines, serpentinous and alabaster. The suitability of a marble for various purposes and its durability or strength are largely determined by the classification under which it properly falls. The characteristics of the several classes and the means of determining their suitability are well described in the book before us.

The methods of quarrying marbles, though interesting, are of minor importance to architects, except in so far that certain processes are more likely than others to lead to the production of unsound blocks. The nature of the machinery employed in the working of marble after it has been won from the quarry is of greater consequence, as it necessarily determines the forms in which marble can most advantageously be worked, and hence the details of the architect's designs.

As in modern times we do not use marble for the reason that the Greeks used it, its excellence as a building stone, but for the beauty of its colouring and surface texture, the list of marbles in ordinary use given by the author, with descriptive notes and instances of their application, mentioning buildings in which they can be seen, will be to architects the most useful part of the book, particularly with the accompaniment of the very excellent and beautifully printed coloured plates of typical specimens of coloured marbles.

Marble being a material peculiarly liable to imperfections and to damage in working, it is desirable not to make the lowest tender an element in selection, as this leads to faking, cramping and stopping to an extent not inherently requisite, but facilitating cheapness. It is highly advisable also that the marble should be worked at home and not abroad, so that the architect may have an opportunity of inspecting, and if necessary refusing, the material before the work is completed ready for fixing. Marble being usually part of the finishing of a building one is tempted to pass for the avoidance of delay material that would have been condemned if it had been inspected at an earlier stage; hence the importance of the architect having the work under control at as early a period as possible.

* *Marble and Marble Working.* By W. G. Renwick. (London: Crosby Lockwood & Son. 15*s*.)

ARCHITECTURE: ITS TRUE PRINCIPLES.—VII.

By R. OWEN ALLSOP.

Unity of Mass.

UNITY and harmony are in some sense correlative terms. A subordination of component parts serving the common weal is implied. In architectural composition this harmony may not be always a matter of size, although as a general rule the essential spirit of gravitation—the mastery of the larger over the smaller—must hold true. Generally, it is impossible to increase the size of any part without giving it real increased importance and making it more dominant. This is but natural, seeing that gravity is a property of inert matter, and it is of inert matter we build. Moreover, seeing that simplicity and dignity go together, it does not seem reasonable to expect that mere work upon the smaller mass will enable it to hold its own in competition with the larger bulk. Would any kind of decorative treatment of one of the small Egyptian pyramids enhance its importance as contrasted against the Great Pyramid? It may, therefore, be taken as a quite safe rule founded on natural law, that bulk and importance are practically the same in architectural composition. If we increase the mass its importance increases in direct ratio. We cannot help but be more impressed by the aspect of the Matterhorn than by a mole-hill. From these considerations we may establish a rule that if any feature in major massing is obtruse and destructive of unity it is too large and must be reduced. The requirements of due domination and subordination in building masses are the harmonious relation of parts, and this is as much a matter of size, as weight is concerned with gravity.

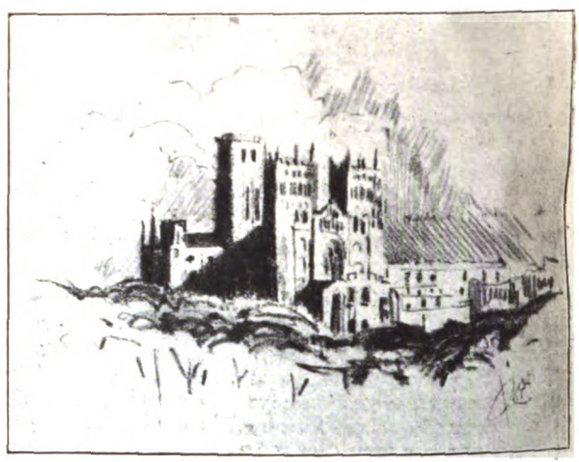

Fig. 16.—DURHAM.

Unity, therefore, in architectural composition results from due weight being given to every feature relative to its importance, as harmony in the house results from the absence of aggressive individuals; and just as the "strong" man may band together a nation, so the dominant feature of a whole architectural composition will preserve the unity. It is worth noticing that any levelling down of features of a design does not give an effect of harmony but of anarchy. The binding power of the dominant feature—be it merely a large roof or a plain chimney-shaft—is only observed if obliterated from a design (or by hiding it in a perspective view), and many a large group of institution buildings has been saved from being a nonentity by its water tower. Ruskin has advised architects to have one large thing and a lot of little things, and

Digitized by Google

has drawn attention to the general poverty of effect of four pinnacles on a square tower without some central feature to which they may refer. He instances a king and his train of courtiers. It is worth noting that the king must be such actually. If there be two such the position is as hopeless as two actual kings on one throne. The consideration introduces important facts as to the

Fig. 17.—SOUTHWELL MINSTER.

arrangement of masses in composition. It may be asserted that (for harmony) two entities necessitate a third, actual or implied. Let us imagine two towers built independently and placed side by side, not, however, actually joined. No arrangement of these two objects alone can form them into one entity.

If placed close they war one with other. The further they are separated the less they affect each other. At what might be a reasonable distance for two towers in a building they remain independent, individual units. Placed almost touching they look ridiculous—at the best like two hounds in leash striving to get apart. Two objects require a third for unity—harmony. It may be merely

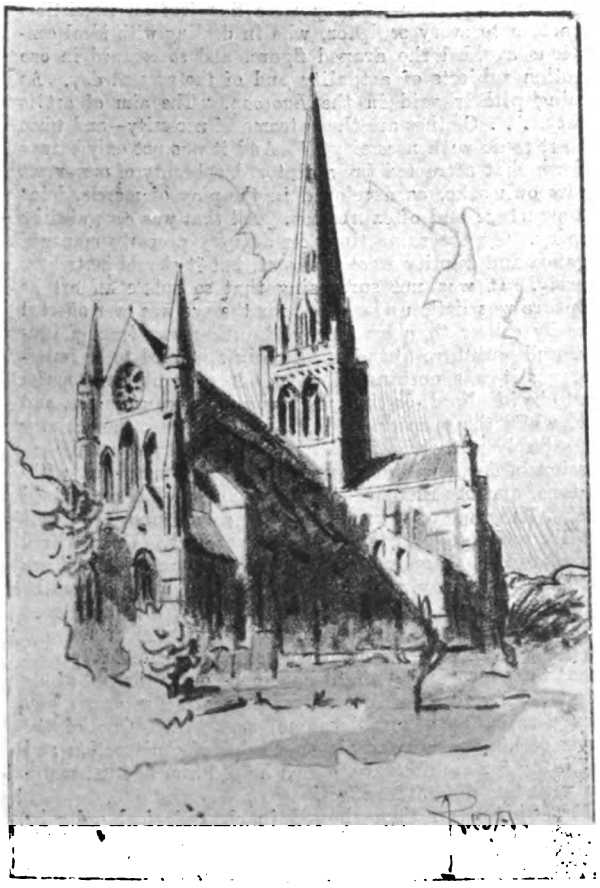

Fig. 18.—CHICHESTER.

a bond of sympathy—something spiritual—but that third part, whether spiritual, abstract or concrete, is required before the two individual entities can be subordinate to one harmonious whole. In matter of fact architecture a very little will connect the two—a wall, a gable, a screen, but no effect is produced unless the connecting object be of itself an entity that is not merely a wall. And we are therefore led to conclude that whereas with two objects the greater in bulk must be the important and the less subordinate, if we add a third part of equal bulk to the heretofore dominant, the smaller part may be rendered dominant over the two of the greater bulk. But it is an essential point in this that the smaller be placed between the two. More correctly the two should be placed on either side of the one; for the twin towers of a cathedral western front are referable to the central nave, and not the nave to the side towers. Generally we may deduce a rule that an object may be rendered important by flanking it, and further that the centre must be always dominant of the wings. The end gable and wall of a cathedral nave is of itself an inferior mass to that of the combined twin towers, but the effect on the beholder is plain enough, the towers refer to, support and add dignity to, the central feature—they are in the nature of servants. And it is remarkable of this arrangement of centre and wings that

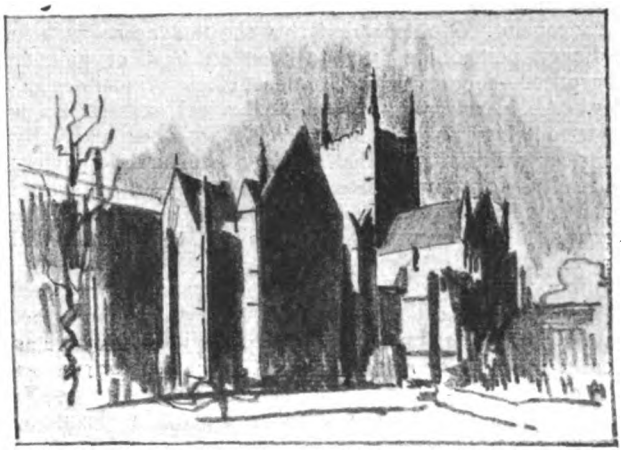

Fig. 19.—ROCHESTER.

no measure of size, no added work or ornament to the two flanks, can ever diminish the effect of the central object. It is as it were that the glory of the servants only increases that of the object served.

These considerations show that a composition—a façade, say—composed of two wings without a central feature is bad; a mere wall or colonnade connects the two, but only as by a chain. The eye always seeks a centre, just as we look for a centre of interest in a picture or a definite theme or motive in literature and music.

Every circle must be considered to harmonise with every other circle, however large or small, and however relatively placed. For most complete accord it would appear that they would need to be concentric. Every square must be in harmony with all other squares, however varied in size. In like manner every sphere and every cube are in harmony, contrasting in the one case by size and in the other by size and relative angular position. Like forms evidently harmonise by accord. Therefore we may say of Durham Cathedral that it presents in the mass more of unity, or harmony, than, for example, Southwell Minster. On a similar line of reasoning, Chichester—as also Salisbury—presents harmonious main masses on account of the accordance in form. For the reason that we criticise Southwell, we might say of the masses presented in fig. 19 that there is no harmony either of accord or by contrast, the ultimate effect being the broken and picturesque merely—"parasitical sublimity." The effect of these masses at Rochester is certainly that of dual personality, and not unity. It seems suggested that a contrast must be by design, for there is no indication that pure harmony has

Digitized by Google

been the aim in the main massing of Southwell; while the great parts of St. Paul's Cathedral are plainly intended to give effect by contrast of form, the spiny sharpness of rectangularity (in perspective) with the dome *viâ* the drum. Were there no drum and dome at St. Paul's, an artist, sketching in sharp perspective, would doubtless introduce soft, "bossy," domical cloud masses as contrast. Wren has given us such effect as a permanency—the rounded dome, and a drum as intermediary—or a modulation; for a dome arising baldly from a rectangular mass must be adjudged offensive, by too violent or inharmonious contrast. To test this point it is only necessary to make a rough sketch — in perspective, always—of such a composition.
